Benefit-Risk Assessment, Communication, and Evaluation (BRACE)

102 | Evaluation of the effectiveness of direct healthcare professional communication regarding new dosage of paracetamol paediatric syrup

Françoise Wuillaume, Martine Sabbe, Javier Sawchik and Jamila Hamdani

Federal Agency for Medicines and Health Products, Brussels, Belgium

Background: In April 2018, a new posology of paracetamol paediatric syrup was introduced in the Belgian market. The composition of the syrup remained unchanged but the dosing pipette was recalibrated to provide 15 mg/kg instead of 10 mg/kg. This change in posology was selected as a case-study to evaluate the effectiveness of Direct Healthcare Professional Communication (DHPC).

Objectives: To determine the proportion of healthcare professionals (HCP) who were informed of the change in posology of paracetamol paediatric syrup in Belgium.

Methods: A cross-sectional online survey was conducted one month after the introduction of the new paracetamol dosage. HCPs were asked if they were aware of the change in posology, source of information and opinion regarding the most reliable source of information. Dissemination of the survey was through email-lists of professional associations and through their websites. The estimated source population was over 8 700 community pharmacists, 1 050 hospital pharmacists, 2 370 paediatricians and 4 500 general practitioners (GPs). Frequencies and percentages of item response were calculated, including 95% confidence interval (95%CI), for the number of respondents overall and per professional category.

Results: Overall, 1 032 HCP responded, including community pharmacists (45%), paediatricians (30%), GPs (18%), and hospital pharmacists (4%). A total of 812 (79%, 95%CI 76-81) respondents reported that they were informed of the change. Awareness was greatest among community pharmacists (92%, 95%CI 89-94) followed by hospital pharmacists (87%, 95%CI 74-94), and paediatricians (77%, 95%CI 72-81). Only 53% (95%CI 45-60) of the GPs reported that they were aware of the change. Professional media (website or newsletters) and DHPC were the most frequently cited information sources. The DHPC was the primary source among 46% (95%CI 31-62) of hospital pharmacists, 42% (95%CI 36-48) of paediatricians, 34% (95%CI 23-45) of community pharmacists, and 25% (95%CI 16-34) of GPs. The DHPC was also cited as the most reliable source of information by 39% (95%CI 36%-43%) of informed respondents.

Conclusions: Although responder bias could have influenced the results, this survey indicates pharmacists and paediatricians were well aware of the new posology. The DHPC and professional information sources played an important role in this communication. We also confirmed the importance to maintain multiple sources of information. However, almost half of GPs were not aware of this change and further investigations are recommended in this professional group.

2372 | Medication storage and disposal in Saudi Arabia: Opportunities for public health improvement

Rasha Almubark, Aljoharah Algabbani, Nora Althumairi and Nasser Bin Dhim

Saudi Food and Drug Authority, Riyadh, Saudi Arabia

Background: Inappropriate drug storage (IDS) and inappropriate drug disposal (IDD) has previously been observed to lead to inappropriate use, accidental poisoning and medication errors. Therefore, many studies have examined patterns and methods of disposing medication and risks associated with it. These studies were carried out in the USA, UK, New Zealand, Russia among other countries worldwide, but almost none in the Kingdom of Saudi Arabia (KSA).

Objectives: This study aims to describe the distribution of IDS and IDD in KSA population, and to describe the characteristic associated with it.

Methods: A cross-sectional national survey using quota sampling, population-based of residents of KSA conducted via in-person interviews.

Results: A total of 801 surveys were available for analysis, the mean age of respondents was 33 (±11). Majority of respondents reported having diabetes and hypertension (58.8% and 31.5%, respectively). Most of respondents reported (fridge 69.1%) as their preferred location for medication storage, (52.1%) reported that stored medications were not kept in a box or cabinet dedicated for medication only. In addition, 48.4% indicated that they store medications at home for emergency uses. Additionally, 71.3% reported throwing medication in the trash, is the method they are using for medication disposal.

Conclusions: Approximately half of KSA residents do not store the medications in a dedicated location, which is contrary to the current Saudi Food and Drug Authority regulations. Future studies are needed to better characterize the distribution and determinants of storing medications at home across KSA. Moreover, existing guidelines need improvement for better disposal options within KSA community.

2588 | Proton pump inhibitor use and the risk of hepatocellular carcinoma: A systematic review of real-world data

Ambrish Singh[1], Robin Jha[2], Salman Hussain[3] and Benny Antony[1]
[1]*University of Tasmania, Hobart, Australia;* [2]*Independent Researcher, Delhi, India;* [3]*Jamia Hamdard, Delhi, India*

Background: Proton pump inhibitors (PPIs) are one of the most frequently used prescription drugs globally. Recently, there have been concerns that PPI therapy is associated with an increased risk of cancer such as hepatocellular carcinoma (HCC). However, the results of real-world clinical studies are conflicting.
Objectives: A systematic literature review was conducted to identify all the evidence and determine the effect of the use of PPI on the risk of HCC based on the published real-world data (RWD) studies.
Methods: We performed a systematic review and meta-analysis of RWD studies, adhering to the PRISMA guidelines, to evaluate the risks of HCC with PPI use. All RWD studies that assessed the risk of HCC in PPI users compared to PPI nonusers were included. We used the generic inverse variance method and RevMan (5.3.5) to meta-analyses the risk ratios (RRs) using a random-effects model. We used Newcastle-Ottawa scales (NOS) to assess the study quality. The study protocol was registered at PROSPERO [CRD42019109885].
Results: Of the identified studies, six (4 cohort and 2 case-control) with more than 33,102 HCC cases were included in our analysis. In PPI users, compared with PPI nonusers, the unadjusted and adjusted risk ratio (RR) for HCC (studies, n= 4) was 1.80 [95 % confidence interval (CI): 1.03 - 3.14, p<0.05] and (n= 6) 1.55 [CI: 1.17-2.82, p<0.05], respectively. When stratified by study design, the risk of HCC, in PPI users compared to PPI nonusers, was significant for cohort studies (n= 4) [1.51 (CI: 1.23-1.86, p<0.05)], and non-significant [1.64 (CI: 0.55-4.87, p=0.38)] for the case-control studies (n= 2). There was a significant heterogeneity (I^2>88%) among the studies and the majority (n= 5) of the studies were of moderate to high quality, based on NOS.
Conclusions: This meta-analysis found a significantly increased risk of HCC in PPI users compared to PPI nonusers; however, the results should be interpreted with caution owing to the inclusion of observational studies with significant heterogeneity.

2600 | Process indicators and outcomes to assess the effectiveness of additional risk minimisation measures in Europe

Esther Artime[1], Nawab Qizilbash[2,3], Rafael Herruzo[1] and Macarena Garrido-Estepa[4]
[1]*Universidad Autónoma de Madrid, Madrid, Spain;* [2]*OXON Epidemiology, Madrid, Spain;* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom;* [4]*Ministry of Science and Innovation, Madrid, Spain*

Background: Good Pharmacovigilance Practice XVI recommends the evaluation of additional risk minimisation measures (aRMMs) with process indicators and outcomes.
Objectives: To describe study designs, measures and results in risk minimisation evaluation plans (RM Plans) that include process indicators and outcomes in Europe.
Methods: A systematic search was conducted using the EU PAS Register, PubMed, and grey literature to identify RM Plans for products involving one or multiple studies to assess the effectiveness of aRMMs via process indicators and outcomes, between 1Jan2011 and 12Oct2019. Process indicators include measures of awareness, receipt, use, knowledge, and self-reported behaviour via surveys. Outcome measures include health outcomes and behavioural outcomes via measures of prescribing, investigations and monitoring. Data were abstracted from study reports, manuscripts and abstracts.
Results: A total of 129 studies involving 102 products were identified. Eighteen products (18%) with RM Plans assessed process indicators and outcomes; 10/18 plans included process indicators and outcomes within the same study. Most products belonged to the antineoplastic and nervous system groups (61%). Two thirds had HCP educational materials, while patient cards were implemented in half of the products. The 18 RM Plans included 29 studies: cross-sectional surveys (66%; 47% targeted patients and 90% HCPs), retrospective designs (59%; 47% using a pre/post approach) and prospective designs (10%). While 62% measured process indicators [receipt (n=14) or use of aRMMs (n=12), level of knowledge (n=17) and self-reported behaviour (n=15)], prescribing behaviour was assessed via drug utilisation studies in 41% of cases and health outcomes were measured in 28%. The proportion of patients receiving the target drug under on-label/off-label conditions, over time, before and after the aRMMs or at a specific data point, was evaluated by 11 of 29 studies. Monitoring of metabolic parameters, reading errors and inappropriate use were assessed by one study each. Outcomes measured were adverse events. Drug utilisation and health outcomes data were mostly obtained from existing healthcare databases (10 of 29). In four RM Plans a correlation between process indicators and outcomes was noted. Study results were available for 14/18 RM Plans.
Conclusions: Only one in five RM Plans identified in this review assessed both process indicators and outcomes, with health outcomes being measured in a minority. Few within-patient correlations between process indicators and outcomes were noted.

2615 | Digital tools for the communication of risk minimization measures for medicines

Michael Forstner
Mesama Consulting, Bärschwil, Switzerland

Background: The primary goal of a Risk Minimization Plan (RMiP) is to develop activities that help patients and healthcare providers understand important risks associated with a drug and to reduce the chance that a serious side effect might occur. The activities implemented by a drug company as part of this plan are called risk minimization measures (RMM). Implementing an RMiP consists of implementing the RMMs, assessing the usefulness of those

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

activities, and using the assessment results to decide if the RMiP needs to be changed.

Objectives: Despite the widespread use of mobile phone apps and other electronic means for the dissemination of information to patients, RMMs are still mostly implemented as paper-based tools, consisting of e.g., educational material packs or patient alert cards. Numerous evaluations by regulators and companies have shown the relative inefficiency of these tools. In addition, paper based tools require an offline means of effectiveness evaluation, such as a survey, and they do not lend themselves to two-way communication. Early attempts to design electronic tools for RMMs consistent mostly of web-versions of the paper material used for educational purposes but did not make use of the full capabilities of digital tools.

Methods: We review different approaches and show that apps designed to deliver information about the safe use of medicines can also be used to allow patients to report experiences pertaining to the safety of the drug and to quality-of-life related issues they may experience in connection with their disease and/or the drug.

Results: The two-way communication allows for a personalized delivery of safety relevant messages to patients and for a real-time evaluation of the benefit-risk profile by feeding into safety signal management tools directly. The evaluation of process and outcome related parameters to demonstrate the effectiveness of risk minimization is simplified as the collection of these parameters is linked to the use of the tool. Furthermore, the collection of meta-data related to the use of the app, e.g., geo-spatial data, behavioral aspects concerning the use of the app, or the frequency, time and duration of use may help to evaluate important real-world parameters associated with the safe and efficacious use of the medicine. The inherent biases associated with data obtained from such sources and ways of accounting for them are discussed as well.

Conclusions: The use of truly digital tools for patient and HCP education has the potential to change the communication on benefits and risks of drugs substantially and integrate risk management of medicines better into clinical care.

2627 | Association between dose and duration patterns of opioid and benzodiazepine use and risk of overdose among U.S. medicare beneficiaries: A group-based multi-trajectory model

Weihsuan Jenny Lo-Ciganic[1], Ting Wang[2], Yong Ge[3], Bobby Jones[4], James Huang[1], Gary Reisfield[1], Jeanne Lee[3], C. Kent Kwoh[3], Juan Hincapie-Castillo[1], P. Chris Delcher[5], Ching-Yuan Chang[1], Debbie Wilson[1] and Walid Gellad[6]

[1]University of Florida, Gainesville, FL;[2]Chinese Academy of Agricultural Sciences, Beijing, China; [3]University of Arizona, Tucson, AZ; [4]University of Pittsburgh Medical Center, Pittsburgh, PA; [5]University of Kentucky, Lexington, KY; [6]University of Pittsburgh, Pittsburgh, PA

Background: Concurrent opioid and benzodiazepine (OPI-BZD) use continues to rise despite clinical guidelines and US Food and Drug Administration black box warnings opposing such. Over 30% of OPI overdose deaths involve concurrent BZD use. Yet, little is known about OPI-BZD dose and duration patterns most associated with OPI overdose risk.

Objectives: To investigate the dose and duration patterns of OPI-BZD use most associated with OPI overdose risk.

Methods: A retrospective cohort study included fee-for-service, non-cancer Medicare beneficiaries initiating prescription OPIs from 2011-2016. During the first 6 months following OPI initiation (i.e., trajectory period), group-based multi-trajectory models identified distinct OPI-BZD dose and duration patterns, based on average daily morphine milligram equivalents (MME) for OPIs and diazepam milligram equivalents for BZDs. We estimated the risk of time to first OPI-related overdose within 6 months following the trajectory period using inverse-probability-of-treatment-weighted Cox proportional hazards models.

Results: Among 337,879 beneficiaries (age≥65=59.3%, female=71.9%, white=87.6%, having OPI overdose=0.31%), we identified 9 distinct trajectories: low-dose OPIs with low or medium-dose BZDs (n=4 trajectories), medium-dose OPIs with medium or high-dose BZDs (n=3), and high-dose OPI-BZD (n=2). The 6-month overdose risk varied by trajectory when compared to beneficiaries with the lowest-dose OPI-BZD trajectory (25.8% of the cohort). The 4 trajectories for low-dose OPIs (<25 MME) with low or medium-dose BZD and medium-dose (25-50 MME) OPIs with medium-dose BZDs were not associated with an overdose risk (42.5%; adjusted hazard ratios [aHR] range=0.32-1.02). An increased risk of OPI overdose was observed in the following 4 higher-dose trajectories: medium-dose OPIs (25-50 MME) with very-high-dose BZDs (9.9%; aHR=2.70, 95% CI=1.12-6.51); medium-dose (50-100 MME) OPIs with medium-dose BZDs (7.9%; aHR=4.95, 95%CI=1.65-14.84); high-dose OPI-BZD use (7.7%; aHR=8.30, 95%CI=2.36-29.11); and very-high-dose OPIs (>250 MME) with high-dose BZD use (5.1%; aHR=7.63, 95% CI=2.44-23.91).

Conclusions: Among Medicare fee-for-service beneficiaries, OPI overdose risks varied substantially across OPI-BZD trajectories. Compared to the lowest-dose OPI-BZD trajectories, individuals with consistently high-dose OPI-BZD use were associated with 2 to 8 times the overdose risk.

2639 | Hypoglycemia-related ED visits and hospitalizations among initiators of insulin analogues compared to NPH insulin

Marie C. Bradley[1], Yoganand Chillarige[2], Hana Lee[1], Xiyuan Wu[2], Shruti Parulekar[2], Stella Muthuri[2], Michael Wernecke[2], Thomas E. MaCurdy[2], Jeffrey A. Kelman[3] and David Graham[1]

[1]FDA, Silver Spring, MD; [2]Acumen LLC, Burlingame, CA; [3]Centers for Medicare & Medicaid Services, Washington, DC

Background: In clinical trials the risk of severe hypoglycemia did not differ between insulin analogues and neutral protamine hagedorn insulin (NPH) for patients with type II diabetes mellitus (T2DM). A recent observational study examining emergency department

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(ED) visits and hospitalizations for hypoglycemia in T2DM patients found similar results.

Objectives: To examine the risk of ED visits and hospitalizations for hypoglycemia among older T2DM patients who initiated long acting insulin or NPH in real world settings.

Methods: A retrospective new-user cohort study of Medicare beneficiaries aged ≥65 years initiating insulin glargine (407,018), insulin detemir (141,588) or NPH (26,402) who did not use other insulins, from January 2007 to July 2019 was conducted. The primary outcome was time to first hypoglycemia-related ED visit or hospitalization, defined using a modified validated algorithm. Propensity score weighted Cox proportional hazards regression was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). In the secondary analysis, recurring hypoglycemia events were modeled using the Anderson-Gill model.

Results: There were 7,347 hypoglycemia-related ED visits or hospitalizations during the study period; 5,194 for glargine, 1,693 for detemir, and 460 for NPH with a median follow-up across the three cohorts of 0.37 years (interquartile range: 0.20 to 0.76). Crude incidence rates (with 95% CIs) were 1.74 (1.69, 1.78), 1.67 (1.59, 1.75), and 3.07 (2.79, 3.35), for glargine, detemir and NPH, respectively. Initiators of glargine and detemir had reduced risk of an outcome event compared to NPH initiators, HRs (95% CIs) 0.69 (0.61-0.77) and 0.69 (0.61-0.79), respectively. When adjusting for concomitant use of oral diabetes medication the HRs did not change substantially; 0.71 (0.63-0.80) and 0.72 (0.63-82). The HR remained unchanged for the recurrent event analysis and the risk of recurrent ED visits and hospitalizations increased with the number of prior events.

Conclusions: Initiation of long acting insulin analogues was associated with a lower risk of hypoglycemia-related ED visits and hospitalizations compared with NPH in older T2DM patients.

3699 | Real-world data collection in early access programs: An additional source of data to inform benefit-risk assessment in the pre-approval phase

Mira Soni[1], Delphine Saragoussi[2], Dara Stein[1], Doug Eckley[3] and Jodie Block[4]

[1]Evidera, London, United Kingdom; [2]Evidera, Paris, France; [3]PPD, Cambridge, United Kingdom; [4]PPD, Wilmington, NC

Background: Early access programs (EAPs) provide patients with life-threatening diseases with access to investigational products prior to market approval. Across EAPs, safety data collection is usually required, but guidance on effectiveness data is limited and can vary by local regulations. The 'real-world data' (RWD) collected in EAPs could supplement trial data in the pre-approval phase, as the investigational drug is provided to a wider range of populations than would be eligible for a trial and patients are monitored as per expected usual practice. However, careful consideration of RWD collection ahead of EAP implementation is needed to ensure data quality to support pre-approval benefit-risk assessment.

Objectives: We developed an RWD framework to collect long-term effectiveness and quality of life (QoL) outcomes as part of an oncology EAP in the United Kingdom (UK). To our knowledge this was the first UK EAP with a voluntary observational study component. Our aim is to share knowledge on optimization of RWD collection in EAPs for future use in benefit-risk assessment.

Methods: During RWD framework development, input/approval on the observational study were sought from the ethics committee and regulatory body stakeholders. As drug supply requests in the UK EAP were physician-led, it was not possible to know in advance which sites would participate, so special circumstances were required to set-up and train sites for data collection within a couple of days of them submitting a drug supply request. For physicians, data collection was limited to key outcomes [disease progression, survival] collected from patient medical records. QoL questionnaires were completed by patients at home.

Results: To ensure data quality to support pre-marketing benefit-risk assessment, the following aspects should be considered ahead of EAP implementation: (1) primary research objectives should be planned and vetted with key stakeholders; (2) expected sample size should be accounted for and ways to improve the reliability of data (e.g. data pooling in multi-country EAPs); (3) a robust data collection platform should be utilized that is easy and convenient for physicians; (4) electronic questionnaires are recommended rather than paper questionnaires; (5) a rigorous safety reporting plan should be in place.

Conclusions: Regulatory bodies are increasingly looking to incorporate RWD in pre-approval benefit-risk assessment. EAPs could contribute RWD, however the related setting and challenges need to be taken into account to ensure quality data that can be considered for drug approval.

3723 | Risk of stroke and bleeding in atrial fibrillation treated with apixaban compared to warfarin

Marie C. Bradley[1], Emily C. Welch[2], Efe Eworuke[1], David Graham[1], Rongmei Zhang[1] and Ting-Ying Huang[2]

[1]FDA, Silver Spring, MD;[2]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA

Background: Apixaban use has been increasing in recent years in the US. A previous FDA study reported a favorable benefit risk for apixaban compared to warfarin for stroke prevention in older non-valvular atrial fibrillation (NVAF) patients. However, that study was restricted to those aged 65 years or more and it remains unclear whether this favorable benefit risk profile persists in other populations including younger users. We examined if a similar benefit risk profile was observed in the Sentinel Distributed Database (SDD), and if it varied by age group.

Objectives: To examine if a similar benefit risk profile was observed in the Sentinel Distributed Database (SDD), and if it varied by age group.

Methods: Patients, 21 years and older initiating apixaban or warfarin for NVAF, between December 28, 2012 and June 30, 2018, were identified in the SDD. Cox proportional hazards regression was used to estimate the hazard ratios (HR) and 95 % confidence intervals (95%

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

CI) for each outcome [ischemic stroke, gastrointestinal (GI) bleeding and intracranial hemorrhage (ICH)] in propensity score matched apixaban users compared to the warfarin users. A subgroup analysis by age (21-64, 65-74 and 75+ years) was conducted.

Results: After matching, 55.3% and 58.4% (n=55,038) of the apixaban and warfarin users were included in the main analysis. GI bleeding was the most common outcome. The HR (95%CI) for GI bleeding, ICH and ischemic stroke in apixaban users compared to warfarin users was 0.57 (0.50-0.66), 0.53 (0.40-0.70) and 0.56 (0.45-0.71) respectively. The reduced risk of these outcomes in apixaban compared to warfarin users persisted across age groups and was lowest in those aged 21-64 years.

Conclusions: In NVAF patients initiating either apixaban or warfarin for stroke prevention, apixaban was associated with a decreased risk of GI bleeding, ICH and ischemic stroke compared to warfarin, and this reduced risk was seen in all age groups.

3736 | Comparative risk assessment of severe abnormal uterine bleeding associated with non-vitamin K oral anticoagulants

Efe Eworuke[1], Laura Hou[2], Rongmei Zhang[1], Hui-Lee Wong[1], Peter Waldron[1], Abby Andersen[1], Audrey Gassman[1], David Moeny[1] and Ting-Ying Huang[2]

[1]US Food and Drug Administration, Silver Spring, MD;[2]Harvard Pilgrim Health Care Institute, Boston, MA

Background: Clinically relevant uterine bleeding has been reported among women of reproductive age, exposed to oral anticoagulants including Non-Vitamin K Oral Anticoagulants (NOACs).

Objectives: To conduct a pairwise NOAC risk assessment for severe abnormal uterine bleeding (SAUB) defined as vaginal bleeding (VB) requiring same-day transfusion and VB requiring surgery (hysterectomy, hysteroscopy, hysteroscopic polypectomy, myomectomy, dilation/curettage, endometrial ablation, or uterine artery embolization) within 30 days after starting NOAC or warfarin.

Methods: We conducted a retrospective cohort study in the Sentinel Distributed Database. Females 18+ years with venous thromboembolism (VTE), or atrial flutter/fibrillation (AF) who newly initiated a NOAC (rivaroxaban [R], apixaban [A], dabigatran [D]) or warfarin [W] from 01/2010 to 09/2015 were included. Patients with hysterectomy, VB, use of oral contraception/antifibrinolytics/vaginal packing, insertion of intrauterine device or study outcome within 183 days were excluded. We followed patients from dispensing date until the earliest of transfusion or surgery following VB, disenrollment, exposure or study end date, initiation of other NOAC or warfarin, or recorded death. Using Cox proportional hazards regression via propensity score stratification, we estimated the hazard ratios (HRs) overall and by age (18-50 and 51+ years), past gynecological disorder, low vs. high NOAC dose, and NOAC indication. Four pairwise comparisons were conducted; R-D, R-A, D-A and R-W for each intervention.

Results: We identified 194,400 rivaroxaban, 80,074 dabigatran, 97,784 apixaban and 722,772 warfarin new users. Overall, there was an increased risk of surgical intervention with rivaroxaban when compared to dabigatran (HR: 1.19; 95% CI:1.03-1.38), apixaban (1.23; 1.04-1.47) and warfarin (1.34; 1.22-1.47). No difference in risk was observed for the D-A comparison. Increased risk of transfusion was observed for rivaroxaban compared to dabigatran (1.43; 1.03-2.17) only. For patients with no gynecological history, rivaroxaban was associated with risk of surgical intervention compared to dabigatran (1.22; 1.05-1.42), apixaban (1.25; 1.04-1.49) and warfarin (1.36; 1.23-1.50). No difference in risk was observed for R-D, R-A and D-A comparisons stratified by age and dose for both outcomes.

Conclusions: Our study found increased SAUB risk with rivaroxaban users compared to other NOACs or warfarin. The increased risk was present among women without underlying gynecological conditions.

3739 | Risk of neuropsychiatric adverse events among montelukast users

Efe Eworuke[1], Nicole Haug[2], Andrew Mosholder[1], Noelle Cocoros[2], Marie Bradley[1], Dinci Pennap[1], Elizabeth C. Dee[2], Sengwee Toh[2], Ella Prestine[2], Andrew Petrone[2], Ivone Kim[1], Yong Ma[1], Jennifer G. Lyons[2] and Veronica V. Sansing[1]

[1]US Food and Drug Administration, Silver Spring, MD;[2]Harvard Pilgrim Health Care Institute, Boston, MA

Background: There have been conflicting results from observational studies regarding the risk of neuropsychiatric adverse events (NAEs) with montelukast use.

Objectives: To determine if there are associations of depressive disorders, self-harm, and suicide with use of montelukast compared to inhaled corticosteroid (ICS) use.

Methods: We conducted a retrospective cohort study (01/2000-09/2015) using data from the Sentinel Distributed Database. We identified montelukast and ICS new users, aged 6 years and older, with a diagnosis of asthma (ICD-9-CM: 493.xx) in the six months prior to index dispensing. We excluded patients with chronic obstructive pulmonary disease during the baseline period but allowed comorbid allergic rhinitis. We matched montelukast to ICS users 1:1 on propensity score. Patients were followed from the day after the cohort entry date until a diagnosis of depression, self-harm, or suicide; exposure end date; dispensing of comparator drug, other leukotriene antagonists, long-acting-beta-agonists (LABA), oral corticosteroids, or a combination ICS/LABA product; asthma-related hospitalization; death; disenrollment; or data end date. We estimated hazard ratios (HRs) and 95% confidence intervals (CI) for each study outcome overall and by age, sex, psychiatric history, and pre- and post-2008 labeling updates using Cox proportional hazards regression.

Results: We matched 457,377 montelukast users with 457,377 ICS users. Most NAEs (93%) occurred in patients with a history of a psychiatric disorder. Exposure to montelukast was associated with a lower risk of treated outpatient depressive disorder (HR: 0.91; CI: 0.89-0.93) compared to ICS exposure. No increased risks of inpatient depressive disorder (HR: 1.06; CI: 0.90-1.24), self-harm (HR: 0.92; CI:

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

0.69-1.21), or self-harm using a modified algorithm (HR: 0.81; CI: 0.63-1.05) were observed with montelukast use compared to ICS use.
Conclusions: When compared to use of ICS, no associations between montelukast use and hospitalizations for depression or self-harm events were found. Psychiatric comorbidity was common, and the majority of NAEs occurred in patients with a psychiatric history. Our study outcomes were limited to severe NAEs and early termination of montelukast use to resolve depressive symptoms may have impacted the results.

3744 | Heterogeneity of patient preferences for benefits and risks of antiplatelet therapies

Cathy Anne Pinto[1], Gin Nie Chua[2], Ella Brookes[2], Johanna Hyacinthe[1] and Tommi Tervonen[2]
[1]*Merck & Co., Inc, Kenilworth, NJ;*[2]*Evidera, London, United Kingdom*

Background: Benefit-risk (B-R) profiles of antiplatelet treatments for cardiovascular (CV) disease depend on patient risk factors and preferences for ischemic and bleeding risk, which may also be affected by patient characteristics.
Objectives: To understand myocardial infarction (MI) patient preferences associated with antiplatelet therapies.
Methods: An online discrete choice experiment (DCE) survey was used to elicit MI patients' preferences for ischemic and bleeding risk for antiplatelet therapy: CV death; non-fatal ischemic stroke (IS), recurrent MI, intracranial hemorrhage (ICH) and other non-fatal severe bleeding (OSB). DCE data was analysed using a heteroscedastic multinomial logit model (HMNL), controlling for scale heterogeneity between patients recruited from different sources (access panels vs NHS sites) and preference heterogeneity in subgroups (e.g. age, bleeding risk factors). Maximum acceptable risk of CV outcomes was estimated for a 1% decrease in mortality risk.
Results: 353 patients completed the survey. Majority were male (84%), with median (IQR) age of 65 (59-71) years. Approximately one-third (38%) experienced their most recent MI <1 year prior to completing the survey. Internal validity was high with most patients correctly answering a dominance test (93%), stability test (82%) and trading across choice tasks (99%). The HMNL model had good fit (adj. R^2=0.27) with no significant scale heterogeneity detected between patients recruited from the two sources. For a 1% decrease in mortality risk, patients were willing to accept an increased risk (95% CI) of 0.7% (0.6 - 0.8) for ICH, 1.0% (0.8 - 1.2) for OSB, 1.9% (0.8 - 2.9) for IS. Significant (p<0.001) interactions of MI and age and bleeding risk factors were observed. Older patients (≥65 years) were willing to accept significantly lower increase (1.1%, 95% CI 0.8 - 1.3) in MI risk for 1% mortality risk reduction compared to younger patients (2.1%, 95% CI 1.4 - 2.8). Older patients with ≥1 bleeding risk factor cared less about MI risk than those without bleeding risk factors.
Conclusions: The acceptability of MI risk depends on age and bleeding risk factors. This heterogeneity may impact BR profiles for MI patients receiving antiplatelet therapy.

3786 | Can monitoring instructions provided in direct healthcare professional communications (DHPCs) be applied in clinical practice? - A retrospective analysis of DHPCs sent out between 2007 and 2018

Christine E. Hallgreen, Arnela F. Boskovic, Maja-Marie G. Højer and Marie Louise de Bruin
Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

Background: Direct to Healthcare Professional Communications (DHPC) are one of the most used additional risk minimisation measures. Around 10% of all drugs require regulatory action to inform healthcare professionals about new safety concerns that appear after marketing approval. Often DHPCs include instructions to monitor patients. However, the effectiveness of DHPCs and their usability in clinical practice has been criticised.
Objectives: In this study we assessed whether DHPCs are applicable in clinical practice and how the applicability differs according to safety concerns and type of monitoring.
Methods: A retrospective cohort study of DHPCs containing monitoring instructions issued in Denmark between 2007 and 2018 was conducted. Clinical applicability of monitoring instructions was assessed according to the Systematic Information for Monitoring (SIM) score. Associations between different characteristics of instructions and the SIM score were compared with analysis of variance (ANOVA) and the post hoc test Tukey's HSD if significant.
Results: In total, 297 DHPCs were issued, of which 97 contained 134 monitoring instructions. For 95% of these DHPCs the European Medicines Agency was involved. The average SIM score was 2.551.57 (range 0-6) and only 47% were considered applicable in clinical practice (SIM score 3). In addition, even fewer (11%) instructions were considered a "sufficient instruction" which also reported about facts and risks. Differences between clinical applicability according to type of monitoring were observed, specifically between clinical monitoring (SIM score 1.9) and biomarker monitoring (physical SIM score 2.9, p=0.029, and laboratory SIM score 3.4, p<0.0001).
Conclusions: Monitoring instructions were found not to be clinically applicable according to the SIM score. Our study concludes the need for further research and regulatory steps to ensure clinical applicability of safety communications.

3818 | Evaluation of spontaneous adverse event reports for hepatocellular carcinoma attributed to sofosbuvir and its combinations within the FDA adverse events reporting system

Mai M. Salama[1], Ahmed M. Elkersh[2] and Mohamed A. Mekkawy[3]
[1]*Biomedical Informatics and Medical Statistics Department, Medical Research Institute, Alexandria University, Alexandria, Egypt;*
[2]*Epidemiology Department, High Institute of Public Health, Alexandria University, Alexandria, Egypt;* [3]*Medical Statistics Department, High Institute of Public Health, Alexandria University, Alexandria, Egypt*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Few trials have reported conflicting results about development or recurrence of hepatocellular carcinoma (HCC) among patients treated with direct-acting antivirals (DAAs). However, no study has analyzed spontaneous reports of HCC with these drugs.

Objectives: To describe and evaluate spontaneous adverse event reports of HCC attributed to sofosbuvir and its combinations.

Methods: We identified adverse events reports listing sofosbuvir or sofosbuvir and its combinations in the FDA Adverse Events Reporting System (FAERS) from July 2014 to September 2019. We used the terms "sofosbuvir," "voxilaprevir," "glecaprevir," "pibrentasvir," "ledipasvir," "dasabuvir," "ombitasvir," "paritaprevir," "ritonavir," "elbasvir," "grazoprevir" and "velpatasvir" to identify sofosbuvir and its combinations. Hepatocellular carcinoma (HCC) MedDRA term was used to identify HCC events. We calculated the proportional reporting ratio (PRR) and the reporting odds ratio (ROR) for each drug.

Results: Among 3,258,771 FAERS reports between July 2014 and September 2019, 28,894 (0.9 %) reports mentioned DAAs, 5546 (19 %) mentioned sofosbuvir, 16131 (56 %) mentioned sofosbuvir /ledipasvir, 6609 (23 %) mentioned sofosbuvir/velpatasvir, and 608 (2.0 %) mentioned sofosbuvir/velpatasvir/voxilaprevir. There were 2642 (9 %) HCC reports during the same period of which 602 reports (22.8 %) were attributed to sofosbuvir combinations, 301 (50 %) were attributed to sofosbuvir, 244 (40.5%) were attributed to sofosbuvir /ledipasvir, 42 (7 %) to sofosbuvir/velpatasvir, and 15 (2.5 %) to sofosbuvir/velpatasvir/voxilaprevir. The PRR for sofosbuvir was 75.42 (95% CI: 67.09, 84.79), for sofosbuvir /ledipasvir was 20.45 (95% CI: 17.95, 23.31), for sofosbuvir/velpatasvir was 7.95 (95% CI: 5.86, 10.77), and for sofosbuvir/velpatasvir/voxilaprevir was 30.6 (95% CI: 18.54, 50.51) respectively, and the ROR were 79.69 (95% CI: 70.47, 90.13), 20.75 (95% CI: 18.18, 23.7), 7.99 (95% CI: 5.8, 10.8), and 31.35 (95% CI: 18.75, 52.4) respectively.

Conclusions: Although FAERS is subject to significant limitations, the results suggest that sofosbuvir and its combinations have a statistically significant association with an increased incidence of HCC. Further studies are promptly needed to investigate this risk.

3826 | Risk of non-melanoma skin cancer associated with hydrochlorothiazide-containing products in the United States

Efe Eworuke[1], Nicole Haug[2], Marie Bradley[1], Austin Cosgrove[2], Elizabeth C. Dee[2], Sruthi Adimadhyam[2], Hana Lee[1], Tiffany Woodworth[2] and Sengwee Toh[2]

[1]US Food and Drug Administration, Silver Spring, MD;[2]Harvard Pilgrim Health Care Institute, Boston, MA

Background: Recent studies conducted in Europe report an increased risk of non-melanoma skin cancer (NMSC) with hydrochlorothiazide-containing (HCTZ) products. It remains unclear whether the observed risk applies to the US.

Objectives: To determine whether there is an increased risk of NMSC among patients exposed to HCTZ compared to patients exposed to angiotensin-converting-enzyme inhibitors (ACEIs).

Methods: We conducted a retrospective cohort study (January 2000-August 2018) in the Sentinel Distributed Database. Patients at the time of dispensing were followed until a diagnosis of squamous cell carcinoma (SCC) or basal cell carcinoma (BCC) (ICD-9: BCC: 173.x1; SCC: 173.x2; ICD-10: BCC/SCC: C44.xxx) requiring excision; destruction; Mohs microscopic chemosurgery or topical chemotherapy treatment on or within 30 days after the diagnosis date; or a censoring event (non-outcome cancer, radiation or chemotherapy, disenrollment, or death). Using Cox proportional hazards regression analysis via 1:1 propensity score matching, we estimated the hazard ratios (HRs) of NMSC overall and separately by age, gender, and race. We also examined site- and age-adjusted incidence rate ratios (IRRs) by cumulative HCTZ dose within the matched cohort.

Results: After propensity score matching, 5.2 million HCTZ and 5.2 million ACEI users were retained for analyses. Overall, there was no difference in risk between HCTZ and ACEI of BCC (HR: 0.99; 95% CI: 0.97-1.00) but an elevated risk of SCC (1.04; 1.02-1.06). Elevated risks of BCC (1.09; 1.07-1.11) and SCC (1.15; 1.12-1.17) were observed among Whites. An increased risk of SCC was also observed in males (1.06; 1.03-1.09) and older patients (1.05; 1.02-1.08 for 60-74 and 1.04; 1.01-1.07 for ≥75 year-olds). Cumulative HCTZ dose of ≥50,000mg was associated with an increased risk of SCC (IRR: 1.19; 1.05-1.35 in all patients and 1.27; 1.10-1.47 in Whites) but not BCC (IRRs 0.93; 0.84-1.02 in all patients; and 0.92; 0.81-1.04 in Whites)

Conclusions: We identified a small increased risk of NMSC associated with HCTZ use. This magnitude of risk should not alter the risk-benefit profile for HCTZ use in the treatment of hypertension. Instead, risk mitigation strategies such as reducing prolonged sun exposure and following up clinically on new skin lesions should be considered while on HCTZ.

3969 | Changes in zolpidem exposure cases in the national poison data system after FDA drug safety communications

Esther Zhou, Zhou Feng, Ellen Pinnow, Joann Lee, Amarilys Vega and Gerald DalPan

Food and Drug Administration (FDA), Silver Spring, MD

Background: The US Food and Drug Administration (FDA) issued two Drug Safety Communications (DSCs) concerning the sleep aid zolpidem, first in January and a follow-up in May 2013, after emerging data from post-approval clinical experience demonstrated a high risk of next-morning impairment.

Objectives: To evaluate the long-term impact of the 2013 zolpidem DSCs, we assessed trend changes in nation-wide zolpidem exposure cases reported to the American Association of Poison Control Centers' (AAPCC) National Poison Data System (NPDS).

Methods: We used the NPDS data to conduct a retrospective study of zolpidem-related call cases in the United States, from 2009 to 2018. We calculated monthly rate of single-product zolpidem exposures per 1,000 AAPCC single-product human exposures.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

We evaluated long-term impact of the FDA's zolpidem DSCs, using interrupted time series (ITS) analysis with seasonal adjustment. We also assessed concomitant exposures for multiple-product exposures involving zolpidem. Cases related to sedating antidepressants (ADs), commonly used for sleep disorders, were used as a comparison group.

Results: During the 10-year period, we identified 74,958 zolpidem and 78,101 sedating ADs single-product exposures; and 87,996 zolpidem and 140,854 sedating ADs multiple-product exposures. Among the single-product zolpidem cases, 25% were children, 59% were female; 40% reported "Intentional - Suspected Suicide"; 31% were admitted to critical care unit or psychiatric care facility. Before the 2013 DSCs, monthly trend for single zolpidem rate was constant with approximately 5 cases per month per 1,000 single-product exposures. The rate dropped to 4 cases immediately after May 2013 (-0.9, 95% CI -1.1, -0.7; P <0.0001); then continuously decreased afterwards compare to baseline (monthly change: -0.03, 95% CI -0.03, -0.02, P <0.0001). Even though there was a significant but smaller increase in AD rate immediately after May 2013 (0.4, 95% CI 0.25, 0.60, P <0.0001), the trend afterward did not change compare to baseline (0.00, 95% CI -0.01, 0.01, p =0.97). Among multiple-product exposures, benzodiazepines were the most frequently reported concomitant drugs involving both zolpidem or sedating AD, in approximately 40% of the cases.

Conclusions: The FDA's zolpidem-DSCs have significant immediate and long-term impact on nation-wide monthly trend of single zolpidem exposure cases. Partial switching from zolpidem to sedating ADs may have occurred in early 2013.

4069 | Retirement of statistical significance testing

Olaf Klungel[1], Kenneth J. Rothman[2], Hans Hillege[3] and John Fletcher[4]
[1]*Utrecht University, Utrecht, Netherlands;* [2]*Research Triangle Institute, Research Triangle Park, NC;* [3]*Dutch Medicines Evaluation Board/ University Medical Center Groningen, Utrecht/Groningen, Netherlands;* [4]*BMJ, London, United Kingdom*

Background: For decades, science has relied on an arbitrary p-value of 0.05 to make a distinction between a statistically significant study result, or not. However, there has been more and more debate about abandoning statistical significance testing in its current form, leading to a recent call by three statisticians to abandon statistical significance (Amrhein V, Greenland S, McShane B,. Retire statistical significance. Nature 2019;567:305-7). The call has been signed by more than 800 researchers, many of which from our society, clearly showing the urgency scientists feel to get rid of the current situation.

Objectives: To identify and understand misconceptions of statistical significance testing. To understand the role of significance testing in decision making on drug approvals from the regulatory perspective and decision making on scientific papers from the perspective of medical journals. To provide alternative ways of interpreting study findings for decision making.

Description: To set the stage, Kenneth Rothman will speak (20 min) about misconceptions related to statistical significance. Using examples of published studies, the audience will get an understanding of why statistical significance testing is misleading. In addition, alternatives for significance testing will be discussed. The second speaker, Hans Hillege will discuss (20 min) the role of significance in regulatory decision making. Lastly, John Fletcher, research editor of BMJ, will speak (20 min) about significance testing from the perspective of a major medical journal.

A panel discussion will be moderated by Olaf Klungel (30 min).

4097 | Evaluation of the physician education component of the ozurdex risk management plan

Laurie Zografos[1], Elena Rivero-Ferrer[2], Staci Abramsky[3], Jean Lou[3], Eric Davenport[1] and Daniel Wolin[4]
[1]*RTI Health Solutions, Research Triangle Park, NC;*[2]*RTI Health Solutions, Barcelona, Spain;* [3]*Allergan, Irvine, CA;*[4]*RTI Health Solutions, Marshall, MI*

Background: In 2014, a survey was conducted to evaluate physician understanding of educational materials (Injector's guide and patient's guide) developed as part of the risk management plan (RMP) for Ozurdex. The educational materials were revised according to regulatory requirements and were redistributed beginning in 2014.

Objectives: To assess the effectiveness of the revised educational materials, a new survey was conducted from October through December 2018.

Methods: In this noninterventional, cross-sectional study, physicians in France, Germany, Spain, and the United Kingdom who administered Ozurdex in the previous 6 months were eligible to complete a web-based, multiple-choice questionnaire designed to evaluate physicians' knowledge and understanding of the educational materials on six knowledge areas: contraindications to Ozurdex injection (6 items), patient preparation for injection (5 items), proper injection technique (7 items), important injection-associated risks (12 items), patient monitoring post-injection (4 items), and importance of counselling patients on symptom reporting (5 items). For each area, the number of physicians considered to have knowledge of that area was determined. Correctly answering $\geq$80% of questions in an area was considered the threshold for knowledge in that area.

Results: Of 4,162 physicians invited to participate, 401 (9.6%) completed the questionnaire. Knowledge of proper injection technique was the highest at 76%. Knowledge of injection-associated risks, the importance of counselling patients on symptom reporting, and contraindications to Ozurdex injection reached 68%, 65%, and 61%, respectively. Physicians were least knowledgeable of patient preparation for Ozurdex injection and patient monitoring post-injection with 31% and 3%, respectively. Only 31% of physicians reported receiving the Ozurdex injector's guide, of whom 82% reported having read it. Variation in knowledge by country was minimal, as were differences in knowledge between physicians who reported receiving the materials and those who did not.

Conclusions: Knowledge varied considerably across information categories, and the proportion of physicians who reportedly received the

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

injector's guide was low. Knowledge was high for most key areas covered by the guide, particularly about injection technique and risks. Knowledge of material from the injector's guide, and recall of receipt of it, may have been affected by the length of time between distribution of the revised materials and the survey, which could have been as much as four years.

4138 | Attitudes of pharmacy students towards patient safety: A multinational cross-sectional study

Abdallah Y. Naser[1], Zahra Khalil Alsairafi[2], Ahmed Awaisu[3], Hassan Alwafi[4], Oriana Awwad[5], Salman Hussain[6], Avinash Kumar Singh[6], Alaa Alsharif[7,8], Fatima B. Jeragh-Alhaddad[2], Angga Prawira Kautsar[9] and Amal Khaleel AbuAlhommos[10]

[1]Isra University, Amman, Jordan; [2]Kuwait University, Kuwait, Kuwait; [3]Qatar University, Doha, Qatar; [4]Umm Alqura University, Mecca, Saudi Arabia; [5]University of Jordan, Amman, Jordan; [6]School of Pharmaceutical Education and Research, New Delhi, India; [7]University College London, London, United Kingdom; [8]Princess Norah bint Abdul Rahman University, Riyadh, Saudi Arabia; [9]Universitas Padjadjaran, Bandung, Indonesia; [10]King Faisal University, Alhasa, Saudi Arabia

Background: Patient safety is one of the main concerns of healthcare systems during the provision of healthcare. Pharmacy programmes globally include content related to patient safety in their curricula. Attitudes of pharmacy students towards patient safety can substantially impact their behaviours.

Objectives: To evaluate the attitudes of undergraduate pharmacy students towards patient safety in six developing countries.

Methods: A cross-sectional study using a pre-validated questionnaire (Walpola et al.) was conducted among undergraduate pharmacy students between October 2018 and September 2019 in six developing countries (Jordan, Saudi Arabia, Kuwait, Qatar, India, and Indonesia). Walpola et al. questionnaire was used in this study. This questionnaire contains five subscales: being quality improvement focused, internalising errors regardless of harm, value of contextual learning, acceptability of questioning more senior healthcare professionals' behaviour, and attitude towards open disclosure, using a five-point Likert scale (range 0-4). Multiple-linear regression analysis was used to identify predictors of positive attitudes towards patient safety.

Results: A total of 2,595 students participated in this study (1,044 from Jordan, 514 from Saudi Arabia, 145 from Kuwait, 61 from Qatar, 416 from India, and 434 from Indonesia). Overall, the pharmacy students had good attitudes towards patient safety with a mean score of 37.4 (SD= 7.0) out of 56 (66.8%). "Being quality improvement focused" scale had the highest score, 75.6%. The scale with the lowest score was "internalising errors regardless of harm", 49.2%. Female students had better attitude towards patient safety score (p= 0.001). Being at a higher level of study and involved in or witnessed harm to patients while practicing were important predictors of negative attitude towards patient safety (p= 0.000).

Conclusions: Patient safety content should be covered comprehensively in pharmacy curricula and reinforced at each year of study. This should focus more on students at their final years of study and who started their training. This will enhance our confidence that the next generation of pharmacists are equipped with the requisite knowledge, core competencies, and attitudes to ensure optimal patient safety when they practice.

4176 | Participation in survey studies of the effectiveness of risk minimisation measures in Europe

Esther Artime[1], Nawab Qizilbash[2,3], Rafael Herruzo[1] and Macarena Garrido-Estepa[4]

[1]Universidad Autónoma de Madrid, Madrid, Spain; [2]OXON Epidemiology, Madrid, Spain; [3]London School of Hygiene & Tropical Medicine, London, United Kingdom; [4]Ministry of Science and Innovation, Madrid, Spain

Background: One main challenge of survey studies assessing the effectiveness of risk minimisation measures (RM studies) is country selection and participant recruitment which may result in selection bias.

Objectives: To describe country selection and subject participation in RM survey studies in Europe

Methods: A systematic literature search was conducted using the EU PAS Register, PubMed, and grey literature to identify RM studies to assess the effectiveness of aRMMs via process indicators and/or outcomes, between 1 January 2011 and 12 October 2019. Survey studies that included at least one European country with process indicators were selected. Participation data were abstracted from study reports, manuscripts and abstracts. Response rate was calculated as the proportion of participants among invited.

Results: Of 129 RM studies, 45 surveys of HCPs and 14 surveys of patients and caregivers were identified. Twenty-eight different European countries were included in the HCP surveys with an average of 5 (Range: 1 to 18) countries per survey. In patient surveys 17 different countries were involved with an average of 5.8 (Range: 3 to 10) countries per survey. The total number of participants was 18316 HCPs and 4129 patients; 17611 and 2996, respectively, with country-specific participation data. The highest recruiting countries in HCP surveys were the UK (34/45), Spain (29/45), France (29/45) and Germany (29/45), contributing 64.3% (by country range: 18.2% to 12.6%) of all participants with country-specific data. Italy, Sweden, Netherlands, Belgium, Austria and Portugal participated in 19, 17, 11, 10, 10 and 4 HCP surveys, respectively, recruiting 21.9% (Range: 2.2% to 6.3%) of all participants. The other 18 countries participated in 1 to 15 studies and provided 13.7% (Ranging from 0% to 2%) of the HCP participants. The median HCP response rate by country ranged from 22.0% to 0.3%, being highest in Greece (22.0%), Italy (19.0%) and Czech Republic (18.4%). The UK (13/14), Germany (10/14), France (9/14) and Spain (7/14) were also the top recruiters in the 14 patient surveys, recruiting 65.7% of all participants with country-specific data. The median patient response rate by country ranged

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

from 90.3% to 10.0%, being highest in Spain (90.3%) and Germany (78.9%)

Conclusions: Some countries are overrepresented in HCP and patient RM survey studies. Subject participation remains low, especially in patient surveys. Strengthened recommendations to guide country selection and participation are warranted.

4187 | Pregnancy outcomes among women exposed to potentially harmful drugs

Thuy Thai[1], Amir Sarayani[1], Yasser Albogami[1,2], Xi Wang[1], Sabina Nduaguba[1], Preya Patel[1] and Almut Winterstein[1,3,4]

[1]College of Pharmacy, University of Florida, Gainesville, FL;[2]College of Pharmacy, King Saud University, Riyadh, Saudi Arabia; [3]College of Medicine and College of Public Health and Health Professions, University of Florida, Gainesville, FL;[4]Center for Drug Evaluation and Safety (CoDES), University of Florida, Gainesville, FL

Background: Only 12 out of hundreds of potentially teratogenic drugs are approved with risk mitigation strategies (REMS) aimed at preventing fetal exposure in the US. The public health impact of potentially harmful but non-REMS drugs on adverse pregnancy outcomes is unclear.

Objectives: To evaluate the risk for pregnancy loss and malformation associated with potentially harmful non-REMS, REMS and non-potentially harmful drug exposures during early pregnancy.

Methods: We conducted two retrospective cohort studies using the IBM MarketScan Commercial Claims data 2005-2018. Women aged 12-55 years old had a continuous enrollment from 180 days before conception to pregnancy end date for non-livebirth or 30 days after pregnancy end date for livebirth. Linked infants had ≥30 days enrollment after birth or ≥90 days enrollment after birth for malformation evaluation. Potentially harmful drugs were based on the Teratogen Information System including drugs with ≥moderate level evidence on teratogenicity or with indication for potential teratogenicity from animal studies and labeled pregnancy contraindication (269 drugs). Women with any drug fill from conception to first trimester end were classified into three groups: REMS (REMS), potentially harmful non-REMS (non-REMS), and non-potentially harmful (non-harmful) drug users. Pregnancy loss and major malformation were compared between non-REMS vs non-harmful drugs and between REMS vs non-harmful drugs in cohort 2. We adjusted for maternal age, gestational age at first prescription fill, demographics, and a variety of maternal characteristics using clinical classification software condition categories. We used standardized mortality ratio weighting and generalized estimating equation models to estimate adjusted absolute risk difference (ARD) and risk ratio (RR).

Results: A total 1,038,584 pregnancies were included: REMS (0.03%), non-REMS (8.7%), and non-harmful (91.2%) drugs. Adjusted ARD between non-REMS and non-harmful drug users was 8.0% (95%CI 7.5-8.4%) and 0.4% (95%CI -0.03 to 0.9%) and RR was 1.30 (95%CI 1.28-1.32) and 1.06 (95%CI 1.00-1.13) for pregnancy loss and malformation, respectively. In cohort 2 comparing REMS and non-harmful drug users, ARD was 22.0% (95%CI 12.3-31.8%) and RR was 1.78 (95%CI 1.36-2.37) for pregnancy loss. Due to small number of livebirths in REMS users, malformation was not evaluated.

Conclusions: Both REMS and non-REMS potentially harmful drugs showed increases in adverse pregnancy outcomes but despite broad adjustment, confounding may contribute to this finding. More studies should address non-REMS drugs individually to quantify teratogenic burden.

4239 | Medication errors current situation in Saudi Arabia; A nationwide observational study

Khalidah A. Alanazi[1], Yasser Alatawi[2], Ali F. Altebainawi[3] and Thamir M. Alshammari[4,5]

[1]Ministry of Health, Tabuk, Saudi Arabia; [2]University of Tabuk, Collage of Pharmacy, Tabuk, Saudi Arabia; [3]Ministry of Health, Hail, Saudi Arabia; [4]Saudi Food and Drug Authority, Riyadh, Saudi Arabia; [5]Medication Safety Research Chair, King Saud University, Saudi Arabia

Background: Medication errors is a global concern that lead the World Health Organization to have an initiative aiming to reduce the medication errors worldwide.

Objectives: The objective of this nationwide study was to estimate the prevalence of medication errors, characterize the type of errors and determine the stages of the medication process in which the errors occurred. In addition, we aimed to identify the groups of healthcare providers who detect and report errors, as well as the potential causes of the errors and classes of medication involved.

Methods: A retrospective observational study that assessed all medication errors reports that were submitted to the general pharmaceutical care department database from 265 government hospitals and primary care centers for the period of March 2018 to June 2019. The database was structured to include information regarding all aspects of medication errors, including patient information, medication information, error information, causing the error and reporter information. The medication use process was categorized into ordering/prescribing, transcribing, dispensing, administration, and monitoring. All data were analyzed by using the Statistical Analysis Software (SAS), version 9.4

Results: About 71,332 medication errors reports were submitted to the pharmaceutical care in ministry of health database during the period between March 2018 to June 2019. The medication error rate was estimated to be 0.15% and most of errors were frequently made by physicians 63120 (88.5%) and were primarily detected by pharmacists (75.9%). The majority of errors were detected at the prescribing stage (84.8%), followed by the transcribing (5.8%), dispensing (5.7%) stage and only 4,182 (5.8%) errors reached patients. Medication errors were frequently reported for medication taken orally (56.5%). Antimicrobials were the most commonly associated drugs with a medication error (24.3%). Work overload of the staff was associated with one-third of the reported error (31.6%) and 22.7% of the errors were due to lack of experiences and training among health care providers.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: This study found that medication errors were more likely to occur in the prescribing phase and mainly detect by pharmacists. The majority of factors contributing to medication errors were human-related, such as increased workload and non-compliance with policy and procedure. It is important that we focus on improving our understanding of the scope and nature of errors and implement policies and procedures that will improve patient safety.

4295 | How patient preferences can inform net clinical benefit: A personalized, patient-centered, benefit risk assessment using real-world and clinical trial data

Tommi Tervonen[1,2], Thibaud Prawitz[1], Gin Nie Chua[1], Johanna Hyacinthe[3] and Cathy Anne Pinto[3]

[1]Evidera, London, United Kingdom; [2]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Merck & Co., Inc, Kenilworth, NJ

Background: Drug benefit-risk (BR) assessments have traditionally been informed with clinical trial data with equal or arbitrary weighting of outcomes. Characterization of the expected BR profile in the real-world (RW) requires additional understanding of how risks and their tolerance vary within the population receiving treatment.

Objectives: To estimate the patient-centered net clinical benefit (NCB) of an oral antiplatelet, vorapaxar, in terms of key treatment outcomes including ischemic benefit and bleeding risks.

Methods: A database study identified patients with a prior myocardial infarction (MI) in the Clinical Practice Research Datalink, linked to the Hospital Episode Statistics and Office of National Statistics databases. Risk prediction models were developed to estimate baseline risk of each NCB outcome for each patient over 3-years of follow-up. A separate preference study using a Discrete Choice Experiment (DCE) to elicit trade-offs among these outcomes from MI patients was conducted with recruitment via access panels and National Health Service (NHS) in England. DCE data was analyzed using a heteroscedastic logit model. The drug's hazard ratios relative to placebo, as observed in the pivotal RCT, were applied to baseline risk estimates to compute expected attributable risks which were weighted to estimate the per-patient NCB. Attributable risks were weighted equally and with patient preference data.

Results: Complete-case database sample included 22,125 adults with median (IQR) age of 72 (61-81) yrs, 64% male. The DCE was completed by 353 MI patients with a median (IQR) age of 65 (59-71) yrs, and 84% male. In the DCE, patients >=65 yrs of age with no other bleeding risk factors valued reduction of MI risk higher than younger patients or those with additional bleeding risk factors. Using equal weighting and preference weighting, the relative NCB for patients within the highest and lowest deciles of baseline cardiovascular risk ranged between 9-12% and 2-3%, and between 8-11% and 1-2%, respectively. Mean NCB was significantly lower in the preference weighted than in the equal weighted analysis (4.3 vs 5.7; p<0.001). Sensitivity analyses showed that 100% of patients would maintain a positive NCB in the equal- and preference-weighted analyses, if bleeding risk increased 12-fold and 7-fold, respectively.

Conclusions: Patient preferences can have a significant effect on the treatment NCB and is an important consideration for patient-centric decision-making processes.

4301 | Handling information about new drug safety issues in Dutch hospitals: A mixed-methods approach

Esther de Vries[1,2], Elisabeth Bakker[1], Peter G.M. Mol[1,2] and Petra Denig[1]

[1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Dutch Medicines Evaluation Board, Utrecht, Netherlands

Background: Risk communication by regulators through Direct Healthcare Professional Communications (DHPC) is primarily focussed at individual healthcare professionals (HCPs). Many new safety issues concern hospital based HCPs but little is known about the routines hospitals have to handle such information. To optimise communication about new drug safety issues it is crucial to align with current ways of handling drug information in hospital settings.

Objectives: Which routines for handling information about new drug safety issues exist in Dutch hospitals?

Methods: We used a mixed-methods design. Semi-structured focus group interviews were conducted with hospital specialists and pharmacists. Based on the focus group results and literature review, a survey was developed, which was distributed among the heads of hospital pharmacies. The survey included questions to assess whether and how new safety issues and DHPCs were addressed in hospital committees, policies, procedures, and agreements.

Results: Of the 15 hospitals approached, 6 agreed to participate in a focus group within their hospital, 3 academic, 2 top clinical and 1 general hospital. The survey was completed by 38 of 79 pharmacies, 2 academic, 16 top clinical and 20 general hospitals. From the focus groups it became clear that safety issues were sometimes discussed in drug formulary committees but DHPCs seldom. New drug safety issues were introduced by individuals at department meetings. The survey showed that only 11 hospitals had hospital wide agreements how to deal with new safety information. Drug safety aspects were considered in drug formulary committees in 24 hospitals, but DHPCs were discussed in only 7. In 30 hospitals, there were agreements on how to deal with new safety information at pharmacy level. DHPCs were evaluated by one of the pharmacists in 27 hospitals. In 4 of them DHPCs were also discussed at department meetings, 3 other hospitals did this solely. 18 of the 27 hospitals with a committee for treatment protocols, considered drug safety aspects in these committees. Only 3 hospitals mentioned that DHPCs could change protocols. Although DHPCs are sent to all relevant HCPs, in 13 hospitals pharmacists forwarded the DHPC to prescribers and in 5 to relevant departments. 5 hospitals archived the DHPCs in a quality system.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: In most hospitals, there are no clear routines to handle new drug safety information. DHPCs are at best discussed in the drug formulary committee and/or handled by one of the hospital pharmacists. Currently, individual hospital specialists need to decide for themselves what to do with new safety information.

4372 | Measuring the uptake of pharmacoepidemiologic research through bibliometric analysis: A pilot study from the Canadian network for observational drug effect studies

Robyn L. Traynor[1], Wusiman Aibibula[2], Melissa Helwig[1], Kristian B. Filion[3], Ingrid S. Sketris[1] and Samuel A. Stewart[1]
[1]Dalhousie University, Halifax, NS, Canada; [2]Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, Canada; [3]McGill University, Montreal, QC, Canada

Background: Drug safety research findings are communicated to policy makers, researchers, and health care professionals, in part, by being cited in academic and clinical publications. Understanding how research findings are cited, interpreted, and used is helpful for determining research impact.
Objectives: The objective of this pilot study is to describe the uptake of findings from a Canadian Network for Observational Drug Effect Studies (CNODES) study of the heart failure risk of incretin-based drugs using a bibliometric approach.
Methods: We searched Scopus® (March 24, 2016 - August 8, 2018) for articles citing the CNODES study, Filion et al. 2016 (doi:10.1056/NEJMoa1506115). We downloaded all records to REDCap, removing any that were duplicates or non-English. We conducted content analysis, using a piloted extraction form, to retrieve data related to the citing article and its journal. We applied the Becker Medical Library Model for Assessment of Research Impact and the Canadian Academy of Health Sciences return on investment model to further assess potential impact.
Results: A total of 79 articles citing the CNODES study were analyzed, including 43 reviews, 19 original research articles, and 17 'other' publications, including editorials. The review citations were largely narrative (91%); four were systematic reviews. The CNODES study results were often cited as rationale in background and discussion sections; less commonly, the study's methods were cited. Twenty-four of the citing articles included calculations or reported numbers from the original CNODES study. The majority (96%) of the citing articles were classified as contributing to the "advancement of knowledge" under the Becker Model.
Conclusions: The CNODES study of the heart failure risk of incretin-based drugs was cited in original research and review articles, contributing to a change in understanding and an advancement of knowledge in the field. Further work is needed to determine how results from drug safety studies can be better communicated to policy makers, researchers, and health care professionals to contribute to improving policies, programs, and patient care.

4449 | Patient perceptions on transplant with organs from donors with hepatitis C virus infection

M. Elle Saine[1,2], Erin M. Schnellinger[1], Michaella Moore[3], Ashley J. Woodards[1], Caitlin Phillips[1], David S. Goldberg[4], Peter P. Reese[1] and Frances K. Barg[1]
[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Howard University, Washington, DC; [4]University of Miami Miller School of Medicine, Miami, FL

Background: Historically, many organs from deceased donors with hepatitis C virus (HCV) were discarded. The advent of highly-curative direct acting antiviral (DAA) therapies motivated transplant centers to conduct pilot trials of transplanting HCV-infected organs into uninfected recipients, followed by DAA treatment. These therapies create the potential to significantly increase the number of organ transplants each year. However, factors that influence patients' decisions regarding acceptance of transplant with HCV-viremic organs are unknown.
Objectives: To explore patient-level perceptions, influences, and experiences that inform recipient decision-making regarding transplant with organs from HCV-positive donors.
Methods: We are conducting an ongoing qualitative semi-structured interview study embedded within clinical trials investigating the safety and efficacy of transplanting lungs (Open-Labeled Trial of Zepatier for Treatment of Hepatitis C-Negative Patients who Receive Lung Transplants from Hepatitis C-Positive Donors [SHELTER]) and kidneys (Multi-center Study to Transplant Hepatitis-C Infected Kidneys [MYTHIC]) from HCV-positive donors into HCV-negative recipients. Thematic domains include: 1) chronic illness experience; 2) infection and stigma concerns; and, 3) decision-making processes. Interviews are conducted via telephone and last 20-30 minutes. All interviews are transcribed and systematically analyzed for common themes.
Results: Preliminary data indicate that the curability of HCV with DAA therapies had varying impact on patients' decisions to receive transplant from HCV-positive donors. Some participants feel that curative DAA treatment made the risk of receiving HCV-positive organs comparable to other transplant risks (e.g. receiving organs from older donors), while others are concerned about the limited clinical trial data. Participants frequently express concerns regarding the risk of transmitting HCV to loved ones post-transplant, specifically during DAA treatment.
Conclusions: The potential to cure HCV through DAA therapies offers promising opportunities to patients in need of transplant, as it could dramatically increase the number of donor organs available. However, preliminary qualitative interview data suggest that patients' willingness to accept HCV-positive organs varies, as do their perspectives on the attendant risks of receiving such organs. Ongoing research aims to further elucidate factors informing patient decision-making regarding transplant with HCV-positive organs.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4852 | Stakeholders' perspective in implementation of additional risk minimization measures: reflection on challenges and solutions

Harshil Patel
APCER Life Sciences, Ahmedabad, India

Background: Additional risk minimization measures (ARMMs) are developed as regulatory commitment to inform healthcare professionals and patients on the risks associated with a particular product including measures to mitigate them. Any non-compliance in implementation, and effectiveness assessment of the ARMMs have a critical impact on safety and well-being of the patients. The implementation and determination of effectiveness for ARMMs can be a challenge as it involves multiple stakeholders.

Objectives: 1) To understand the pharmaceutical industry Stakeholders' perspective to meet the legal obligation of global ARMM commitments including implementation and effectiveness assessment. 2) To identify the root cause of non-compliance of RMP commitments and related solutions

Methods: To understand the challenges faced by industry for RMP commitments, three-way analysis of MHRA GPvP metrics 2017-18, author's experiences and Stakeholders' perspectives through anonymous survey was undertaken using online SurveyMonkey® application.

Results: Three-way analyses revealed critical lack in adherence to RMP commitments [failure in additional risk minimization measures (aRMMs) implementation and effectiveness assessment, specific data monitoring in lieu of a Post Authorization Safety Studies (PASS) and targeted follow-up of events] and lack of robust process (including aRMM tracking, outreach to target audience, lack of awareness and resource crunch) for RMP implementation at Marketing Authorization Holders' end. Challenges like aRMM translation and version management during national approval (36%); distribution, stakeholders training and budget during implementation of aRMMs (40%); and higher chances of manual miss due to use of excel based tracking tools (55%) were identified from survey results of 38 respondents comprehend author's experiences and GPvP metrics. Effectiveness assessment included post-marketing incidence and reporting rates, and drug utilization studies. Possible challenges in RMP commitments implementation and tracking require collaborative approach. Solutions focusing on ARMM education, local market alliance and multi-faceted IT tools can be supportive aids to ensure that legal obligations are met and risk to the patients are adequately communicated and mitigated.

Conclusions: Maintenance of products with complex risk management systems is always a challenge and such systems are under the scanner of the inspectors. Multi-prong solutions would increase visibility of measures reaching target and achieve the objective of risk reduction.

4880 | Deprescribing of inappropriately consumed proton pump inhibitors and its clinical consequences: A prospective study

Eswaran Maheswari
M.S. Ramaiah University of Applied Sciences, Bangalore, India

Background: Deprescribing is the process of ceasing, tapering or substituting inappropriate medication(s). Proton Pump Inhibitors (PPI) are consumed inappropriately which may lead to increased occurrence of Adverse Drug Reactions (ADR).

Objectives: The aim of the study is to deprescribe inappropriate consumption of PPI among PPI chronic users and assess the clinical consequences of deprescribing.

Methods: This is a prospective interventional study carried out for a period of 11 months after obtaining ethical approval. Patients more than 18 years of age consuming PPI were included. Based on endoscopic report, medical records and expert opinion the patients were classified as "clearly appropriate", "likely appropriate" and "potentially inappropriate". The "potentially inappropriate" patients were counseled on harms of inappropriate PPI usage, impact of healthy dietary and lifestyle habits employing a Patient Information Leaflets (PIL). The patients deprescribed were followed up through telephonic communication. Global Overall Symptom scale (GOS) was utilized to assess gastric discomfort before and after deprescribing.

Results: From the 745 patients recruited, 226 (30.33%) were classified under "potentially inappropriate", out of which 113 (15.16%) were deprescribed. When paired t-test was applied, GOS scale indicated significant difference in symptoms before and after deprescribing (P- value<0.01).

Conclusions: Deprescribing of PPI decreased the incidence of long-term ADR, cost burden and promoted healthy lifestyle and therefore, may help improve the Quality of Life (Q0L).

4983 | Establishing drug safety and effectiveness strategies in low and middle income countries

Edward Mills[1], Nathan Ford[2] and Sabin Nsanzimana[3]
[1]Bill and Melinda Gates Foundation, Seattle, WA; [2]World Health Organization, Geneva, Switzerland; [3]Rwanda Biomedical Centre, Kigali, Rwanda

Background: Low and middle income countries now have emerging markets for medical products that have not been evaluated in their local setting. There is a need for local evaluations assessing the appropriateness of drug availability, efficacy, safety and cost-effectiveness. These settings are unique as the efficacy and safety data is rarely from LMICs and the quality of medical components varies widely.

Objectives: This session will address the need and process to develop local administrative skills for the assessment of safety, efficacy, and economic evaluations of external data for local settings in LMICs.

Description: Low and middle income countries represent an emerging pharmaceutical market and established drugs are now being marketed in these settings. Many LMICs do not have oversight agencies to assess the efficacy, safety or applicability of these drugs in their markets. This is unique to LMICs as the efficacy and safety data has rarely been collected in similar settings. The World Health Organization (WHO) offers guidance on the use of drugs for low income settings but does not take into consideration the heterogeneity of markets within countries and

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the use of drugs without local guidance. This session will debate whether there is a need for a general (WHO like) oversight agency, regional agencies, or national agencies. There is limited infrastructure in many settings to evaluate drug applicability and a need for specialized human resources for drug technology evaluations. The panel will begin (10 minutes) with an overview of capabilities in LMICs addressing current strategies for drug evaluations. We will then have representation from global funders, the WHO, and regional leaders. After the presentations, questions and ideas from the session attendees will be addressed.

5049 | Benefit-harm balance of fingolimod in patients with MS: A modelling study based on FREEDOMS

Alessandra Spanu
University of Zurich, Zurich, Switzerland

Background: Multiples sclerosis is a chronic condition that requires a life long treatment.
Objectives: Our aim was to assess the benefits and arms of fingolimod, an agent employed in MS management, using individual patient data from FREEDOMS trial.
Methods: We modelled each patient health in a scale from 100 (maximum health) to 0 (minimum health/death) including EDSS measurements, relapses, adverse events with their relative drop (loosing of health points) in the scale. We averaged the health status in all arms and compared the difference between them with a predefined Minimal Important Difference (MID). We computed the proportion of patients who profited or declined in health during the treatment. We performed several analyses to evaluate the impact of relapse and AEs different drops in our model.
Results: The main analysis showed that Fingolimod 0.5mg benefits significantly outweighed its harms compared to placebo. The average health status difference of 2.7 (95% CI 2.2 to 3.2, p<0.001) over two years of study. The risk ratio for preventing a relevant decline in health status with fingolimod 0.5mg was 0.53 (95% CI 0.40-0.72, p<0.001), the number needed to treat to prevent one relevant decline in health status was 8. Sensitivity analyses favoured Fingolimod 0.5.
Conclusions: Fingolimod net benefit was not significant when compared to the MID, but the decreased risk in health deterioration could be relevant for patients. This method based on IPD could be useful to evaluate other MS drugs and gives an objective evidence base for guideline recommendations.

5070 | A comprehensive analysis of the characteristics of external control arms in approved oncology therapies

Caitlin Knox, Cherise Wong, Lewis Raynor and Asieh Golozar
Regeneron, Tarrytown, NY

Background: In recent years, there has been a rise in the approval of oncology therapies based on non-randomized clinical trials. The use of historic or external control (EC) arms may provide additional context/supplementary evidence to support the clinical efficacy in the submission of these non-randomized pivotal trials, however the frequency of their application is unknown.
Objectives: To systematically review and characterize the current landscape of EC in the submission of non-randomized oncology trials approved by the European Medicines Agency (EMA).
Methods: A comprehensive search on the EMA's database of European public assessment reports (EPAR) was conducted to extract approvals with single arm trials for anti-neoplastic and immune-modulating agents that were granted accelerated approval, conditional approval, exceptional circumstances or orphan drug designation. No time limitation was imposed. Data elements were extracted by one abstractor and confirmed by the second abstractor.
Results: A total of 27 eligible indications approved between 2001 and 2019 were identified though the EMA EMAR system; 16 indications for hematologic malignancies and 11 for solid tumors. Twenty (74%) of approvals occurred during the past five years; 13 (48%) through the conditional mechanism and three via exceptional circumstances. Use of non-randomized evidence as EC was observed in 14 (52%) approvals. The types of EC submitted included data from retrospective observational studies (9 approvals), literature review (two approvals), pooled or meta-analyses of published literature (six approvals) or a combination of these approaches. Efficacy data was directly compared with the external controls in three approvals and indirectly, in one approval. The choice of EC, description of the EC studies in which they were originally used, and their use in the submission varied across all approved medicines.
Conclusions: Submission of EC as supporting efficacy evidence in non-randomized oncology trials to the EMA is increasing, with the majority occurring in the last five years. There is variability in the design, conduct, and reporting as observed within the systematic review of the EPARs. Additional guidance on the appropriate use of EC and methodological applications may be beneficial and improve the consistency of EC utilization.

Biologics/Biosimilars

27 | Why not biosimilars: Biologic and biosimilar utilization trends in Japanese RA patients

Lu Zhang, Tiffany S. Woodworth and Joseph Menzin
Boston Health Economics, Boston, MA

Background: Lower-costing biosimilars offer opportunities to increase access to biologic treatment for patients with rheumatoid arthritis (RA) and to lower overall health care expenditures in these patients. Since the 2014 market entry in Japan, the impact of biosimilars is largely unknown.
Objectives: To assess the impact of biosimilars and describe utilization trends and patient characteristics in Japanese RA patients.
Methods: We identified patients with ≥1 RA treatment, prior RA diagnosis and 1 year of continuous enrollment in the JMDC Inc. database

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

between January 1, 2005 and May 31, 2019. We calculated annual prevalence of RA treatments: biologics, including biosimilars for etanercept, infliximab, and rituximab; non-biologic DMARDs; glucocorticoids; and methotrexate (MTX). Among new users of biologics, defined as no prior biologic use in prior year, we examined treatment and switching patterns between reference biologics and associated biosimilars. Finally, we examined patient characteristics among those initiating reference biologics vs biosimilars.

Results: Among treated Japanese RA patients, prevalent biologic use steadily increased from 2.7% in 2005 to 18.5% in 2019. MTX use also increased (24.0 to 46.7%). Use of glucocorticoids and other DMARDs decreased (78.1 to 57.9% and 40.2 to 26.6%, respectively). Biosimilars had low uptake (0.1% in 2015 to 1.0% in 2019) despite overall increase in biologics. While prevalence of newer biologics without associated biosimilars increased (0.6% in 2008 to 11.7% in 2019), prevalence of reference biologics peaked to 10.5% in 2011 and have been steadily declining to 6.3% in 2019. Further, new initiators of reference biologics (N=536) stayed on reference for 541 days on average, and 7.3% switched to biosimilars, while new biosimilar initiators (N=37) stayed on biosimilars for 95.5 days on average, and 10.8% switched to reference. Biosimilar initiators tended to be older (50.8 [11.7] vs 47.4 [13.1] years), male (32.4 vs 27.1%), had less outpatient visits in the 12 month baseline period (19.6 vs. 24.6), and were more likely to use MTX at baseline (73.0 vs. 63.1%).

Conclusions: While biosimilars are presumed to increase utilization of biologics due to better affordability, preliminary analysis of biosimilar and biologic uptake and utilization patterns indicate hesitancy to use biosimilars in Japan. Early results seem to indicate that new initiators of biosimilars may have different clinical and demographic attributes compared to initiators of reference biosimilars. Further research should be conducted examine these differences and their impact on biosimilar uptake.

2324 | Monoclonal antibody induced progressive multifocal leukoencephalopathy and cytokine release syndrome: Analysis of Eudravigilance and FAERS databases and risk minimisation measures

Kalindi N. Hapani
APCER LIFESCIENCES, Ahmedabad, India

Background: Monoclonal antibodies (MABs) are used in different therapeutic areas. There has been increased concern for spontaneous reports of progressive multifocal leukoencephalopathy (PML) and cytokine release syndrome (CRS) attributed to MABs that modulate the immune system.

Objectives: 1. To detect the cases of PML & CRS with MABs from FAERS and EudraVigilance safety database and to apply signal detection algorithms to identify significant signals for PML & CRS. 2. To identify the risk minimization measures (RMMs) prevailing in EU & US for PML and CRS with MABs and to discuss the need of awareness in healthcare professionals (HCP) regarding RMMs.

Methods: EudraVigilance and FAERS database were searched using each MAB name approved by EMA & USFDA as suspect drug and adverse reaction of PML and CRS. Proportional reporting ratios (PRR) and 95% confidence intervals (CI) were calculated for MABs with ≥2 case reports. European public assessment reports (EPARs) and REMS database were further explored for the type of RMMs implemented in EU and US.

Results: 72 and 81 MABs were identified by searching the EPARs & Purple Book respectively. About 70% of PML cases and 34% of CRS cases retrieved from both databases were found with MABs. MABs with highest number of PML cases (n=EVD, FAERS) were natalizumab (n=1223, 1658), rituximab (n=847, 1374) and alemtuzumab (n=50, 86). Similarly, MABs with highest number of CRS cases were blinatumomab (n=195, 186), rituximab (n=107, 114) and obinutuzumab (n=6, 45). The percentages of PML & CRS versus all EVD cases for each drug ranged from 0.034% (adalimumab) to 5.28% (natalizumab) and 0.025% (alemtuzumab) to 13.14% (blinatumomab). Similarly, percentages of PML & CRS versus all FAERS cases for each drug ranged from 0.008% (adalimumab) to 1.77% (rituximab) and 0.12% (nivolumab) to 6.06% (blinatumomab). Both EU & US product labels of natalizumab describes PML with guidance on detection and mitigation of PML. Additional RMMs (aRMMs) and REMS are implemented in EU & US respectively for natalizumab. However, no aRMMs or REMS exist for PML for other 4 MABs. For blinatumomab, one of the goals included in REMS is to inform HCPs about the risk of CRS which may be life-threatening or fatal. However, there are no aRMMs in place for blinatumomab in EU.

Conclusions: Our results expand the knowledge of the relationship of MABs with PML and CRS. Calculated statistics and further analysis may reveal a strong signal which requires further study so that patients and HCPs can be communicated regarding these ADRs and its minimisation strategies.

2477 | Long-term safety and effectiveness of etanercept in pediatric psoriasis patients: Results from a prospective observational cohort study

Yun Gu[1], Emma Brinkley[2], Rachel E. Sobel[3], Joel M. Gelfand[4], Marieke Seyger[5], Zsuzsanna Szalai[6], Jean-Philippe Lacour[7] and Mona Ståhle[8]
[1]Pfizer Inc., Collegeville, PA;[2]IQVIA, Durham, NC;[3]United BioSource Corporation, Blue Bell, PA;[4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA;[5]Universitair Medisch Centrum St, Nijmegen, Netherlands; [6]Heim Pál Children's Hospital, Budapest, Hungary; [7]Hôpital de l'Archet II, Nice, France; [8]Karolinska Institutet, Stockholm, Sweden

Background: Etanercept is a soluble TNF receptor fusion protein indicated for treatment of severe plaque psoriasis, and can be prescribed from 6 years of age.

Objectives: The study aimed to evaluate long-term safety and effectiveness of etanercept in pediatric plaque psoriasis patients.

Methods: It was a long-term, prospective, observational study of pediatric psoriasis patients prescribed etanercept and followed for up to 5 years in 8 EU countries. Patients were classified as prospective (starting etanercept within 30 days pre-enrolment or any time after) or retrospective (starting etanercept > 30 days pre-enrolment).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Incidence rate and relative risk were estimated for defined outcomes, with patients classified by timing of AE relative to etanercept: current/recent or previous treatment.

Results: There were 72 patients (32 prospective and 40 retrospective) enrolled at 28 sites, with 51% males. Mean age was 14.5 years with average disease duration of 7.1 years. Patients were followed for a mean of 3. 8 years, with 29 (40%) completing 5 years follow-up. No serious or opportunistic infections or malignancies were reported. There were 25 serious adverse events (SAEs), including 15 SAEs in 11 (15.3%) patients with current/recent etanercept treatment and 10 SAEs in 7 (13.0%) previously exposed, with an incidence rate of 6.21 (95% CI: 3.48 - 10.24) and 8.54 (95% CI: 4.09 - 15.70) per 100 person-years, respectively. Among them, 7 (28.0%) were considered possibly related to etanercept (1 Cholesteatoma, 1 hepatic steatosis, 3 psoriasis and 2 drug ineffective). Infections and infestations were most frequently reported treatment-emergent AE (TEAEs) with 49 events in 19 (26.4%) and 7 events in 5 (9.3%) patients with current/recent exposure and previous exposure, respectively. Among 32 prospective patients, 28 (87.5%) completed at least 24 weeks of therapy, and 5 (15.6%) required ≥ 1 subsequent course of etanercept. Sixteen (50%) required > 1 treatment period with other systemic treatments. After treatment with etanercept, 93.8% (30/32) had a decrease in disease severity. Twenty six (81.3%) prospective patients had ≥ 1 dose change/discontinuation during initial treatment period, with drug ineffective being the most common reason (32.4%).

Conclusions: In this one of the largest studies with the longest follow-up of pediatric psoriasis patients treated with etanercept in the real-world setting, no serious or opportunistic infections or malignancies were observed, and the majority of prospective patients had a decrease in disease severity after etanercept treatment.

2511 | Infliximab use in the Netherlands: Uptake and characteristics of originator and biosimilars over time

Jetty A. Overbeek[1], Josephina G. Kuiper[1,2], Marina Bakker[1], B.J.F. (Bart) van den Bemt[3,4] and Ron M.C. Herings[1,5]

[1]*PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands;* [2]*Erasmus MC University Medical Centre, Rotterdam, Netherlands;* [3]*Sint Maartenskliniek, Nijmegen, Netherlands;* [4]*Radboud University Medical Center, Nijmegen, Netherlands;* [5]*VU University Medical Center, Amsterdam, Netherlands*

Background: To date there is limited data available regarding the general utilization of infliximab and the uptake of its biosimilars in Europe. The nature of the data of PHARMO's In-patient Pharmacy Database allows for distinction between originator and biosimilar and the assessment of multiple centres and indications at once.

Objectives: To provide an overview of the utilization of originator and biosimilar infliximab in the Netherlands in terms of uptake over time and switching patterns.

Methods: All dispensings for infliximab were selected from the In-patient Pharmacy Database of the PHARMO Database Network from 2002 through 2018. Descriptive analyses were performed in order to characterize initiators of originator and biosimilar infliximab and to characterize patients switching from originator infliximab to biosimilar infliximab and patients not switching.

Results: In total, 3,840 patients with 61,274 infliximab dispensings were identified. 2,496 patients initiated an originator infliximab and 777 patients initiated a biosimilar infliximab. Overall, 57% of the patients was female and mean (± standard deviation [SD]) age was 43.2 (± 17.5) years. Both originators and biosimilars were mostly prescribed by gastroenterologists, followed by internists and rheumatologists. After market authorization of the first biosimilar in 2015 the proportion of new patients initiating the biosimilar increased from 39% in 2015 to 91% in 2018. 704 patients were eligible for switching as they had at least one dispensing of infliximab after 01 January 2015. Among these patients 34% switched. Among switchers, the proportion of females was 60% and mean (±SD) age at index was 45.1 (±16.7) years. Among non-switchers, 55% was female and mean age was 39.8 (±17.0) years. The median (interquartile range [IQR]) time to switch was 1.7 (0.6-2.1) years and switchers were most frequently initiated on infliximab by a rheumatologist (42%), while non-switchers were most frequently initiated by a gastroenterologist (42%).

Conclusions: The results of this large population-based cohort show an increase in biosimilar initiation in daily clinical practice. The number of switchers remains relatively low as non-medical switch is not encouraged in the Netherlands. Complete traceability of originator or biosimilar and indication and expansion of PHARMO's In-patient Pharmacy Database would increase the applicability and validity of the current results. Linkage to other databases in the PHARMO Database Network would create possibilities to study outcomes among originator and biosimilar infliximab users.

2605 | Association between biologics and risk of herpes zoster in patients with psoriasis

Chaw-Ning Lee[1,2], Hsing-Chun Hsieh[2], Tzu-Chi Liao[2] and Edward Chia-Cheng Lai[2]

[1]*Department of Dermatology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Tainan, Taiwan;* [2]*School of Pharmacy, Institute of Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Tainan, Taiwan*

Background: Previous studies indicated patients with psoriasis posed a higher risk of herpes zoster (HZ). It raised a concern that use of biologics and other immunosuppressants may increase the risk of HZ. However, only limited evidences on this issue were available and conclusions of the studies remained controversial.

Objectives: To evaluate the association between biologics and risk of HZ in patients with psoriasis.

Methods: We conducted a retrospective cohort study by analyzing the Taiwan's National Health Insurance Database (NHID). We included adult patients aged 18+ diagnosed with psoriasis or psoriatic

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

arthritis receiving biologics (etanercept, adalimumab, ustekinumab, secukinumab) between 2000 and 2016. Patients with biologics were 1:5 matched to patients with non-biologic treatments (methotrexate, cyclosporine, acitretin) by using propensity score, which was derived from logistic regressions considering patients' age, sex, comorbidities and co-medications. The outcome of study was diagnosis of HZ with subsequent use of antivirus agents. We followed up patients for 2 years from initiation of biologics or non-biologic treatments. We censored patients at the date of diagnosis of HZ or death. We used Cox proportional hazards models to examine the risk of HZ between patients with biologics vs. non-biologic treatments.

Results: We identified a total of 4142 and 20,710 patients with psoriasis receiving biologics and non-biologic treatments, respectively. The mean age of patients were 47.6 (SD 16.5) years old and similar between groups. We found the incidence rates of HZ were 175.4 and 127.4 per 10000 person-years for biologics and non-biologic users, respectively. Compared to patients with non-biologic treatments, the adjusted hazard ratio of HZ to patients receiving biologics were 1.56 (95% CIs, 1.27 to 1.92).

Conclusions: We found patients with psoriasis receiving biologics were associated with the risk of HZ. The finding warrants clinical attentions and strategies to prevent the occurrence of HZ infection while using the biologics.

3709 | Different safety reporting profiles of infliximab biosimilar from originator: Comparison among countries

Kimie Sai, Yoshiko Aoki and Yoshiro Saito
National Institute of Health Sciences, Kawasaki, Japan

Background: Usage of biosimilar (BS) of infliximab (IFX) has been encouraged worldwide. One important issue of BS usage is a possible interpopulation difference in its safety profiles; e.g., similar to the originator, immunogenicity of BS might be different among individual/populations and could lead to different efficacy/safety profiles among regions. However, information of safety profiles of BS in real world and possible regional differences is still limited.

Objectives: To examine possible differences in adverse drug reaction (ADR) reporting profiles between IFX originator and BS, and to explore those regional differences.

Methods: ADRs reports of IFX originator (Remicade) and its CT-P13 BS (Remsima/Inflectra/BS 1) were examined. JADER was used in analysis for Japan (Apr 2015 - Dec 2019) and VigiBase (serious report type) was used for global analysis, i.e., Korea, UK, France and USA (Jan 2014 - Dec 2019). Number/percent for ADR reports of either IFX (originator or BS) and reporting odds ratios (RORs) (target vs. non-target drugs) based on MedDRA preferred terms and 27 categories for System Organ Class (SOC) were compared between the originator and the BS. For evaluation of differences in ADR reporting profiles, lower limit of 95% confidence intervals (> 1) for ROR (BS vs. originator) was used.

Results: Major ADRs (either the top or top two SOC) for both originator and BS was "Infections and infestations" in Japan, Korea and UK, "Skin and subcutaneous tissue disorders" in France, and "General disorders and administration site conditions" in USA. Significantly higher ROR (BS vs. originator) was observed in 5 SOC categories in Japan, 2 for Korea, 3 for France, 1 for UK and 7 for USA, of which profile was different among regions. "Injury, poisoning and procedural complications", attributed to "infusion related reaction" was raised to the second BS ADRs in Japan [ROR (95%CI):2.98 (1.70-5.23)], and to the third, but not due to infusion related reaction, in Korea [2.10 (1.08-4.10)]. "General disorders and administration site conditions" was raised to the top BS ADRs, mainly "drug ineffective", in France [2.33 (1.75-3.12)] and, mainly "pain" and "death", in USA [1.36 (1.05-1.76)].

Conclusions: This study suggests that the major ADRs (the top or top two) by IFX would be mostly consistent between originator and BS in each country, but different ADRs might be also raised as major BS ADRs in a region-specific manner. The reason of regional difference might be due to differences in medical practice and population differences among regions. However, further confirmation study is still needed in a larger number of case reports.

3751 | Switching from originator infliximab to biosimilar: Missed dose and discontinuation in a population-based cohort

Cristiano S. Moura[1], Jeffrey R. Curtis[2], Denis Choquette[3], Gilles Boire[4], Gilles Boire[4], Vivian P. Bykerk[5], Walter P. Maksymowych[6], Peter L. Lakatos[7], Waqqas Afif[7] and Sasha Bernatsky[1]
[1]McGill University Health Center, Montreal, QC, Canada; [2]University of Alabama at Birmingham, Birmingham, AL;[3]Institut de Rhumatologie de Montréal, Montreal, QC, Canada; [4]University of Sherbrooke, Sherbrooke, QC, Canada; [5]Hospital for Special Surgery, New York, NY;[6]University of Alberta, Edmonton, AB, Canada; [7]McGill University, Montreal, QC, Canada

Background: Observational studies of patients switching from originator biologic to biosimilar are limited.

Objectives: To compare persistence on therapy between switchers from originator to biosimilar infliximab, versus non-switchers.

Methods: We used Marketscan data (Jan 2017-Dec. 2018) from the United States (US) to study adult individuals (age≥18), switching from infliximab originator to biosimilar. A group of infliximab originator users remaining on the therapy was also identified. Both groups were required to have 3 or more originator infusions (no gap > 90 days between them) in the past six months before the index date (date of first biosimilar infusion). We assessed time to first missed dose (allowing a grace period of 7 days) based on the maintenance schedule (infusion Q8 weeks) and time to complete therapy discontinuation (first 90-day gap between infusions without restarting). We used multivariate Cox regression to compare both outcomes among switchers and non-switchers. Models were adjusted for age, sex, prior use of DMARDs and biologics, baseline systemic glucocorticoids, duration of prior infliximab, calendar period of index date, and underlying disease (inflammatory arthritis [rheumatoid arthritis, ankylosing spondylitis, or

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

psoriasis/psoriatic arthritis], and inflammatory bowel disease [Crohn's disease, or ulcerative colitis]).

Results: We identified 178 switchers to biosimilar and 3,704 who remained on originator. Female sex was 51% among switchers and 56% in the originator group; age was 46±17 in switchers and 42 ±14 years in the originator group. Among switchers, 32.6% missed at least one dose, versus 42.2% in the non-switcher group (9.6% difference, 95% confidence interval, CI 2.2 to 16.2). Complete infliximab discontinuation occurred in 11.0% of non-switchers (11.6% in switchers, difference of 0.6%, 95% CI -3.5 to 6.7). The adjusted hazard ratio (HR) suggested a trend for longer time to first missing dose with biosimilar versus originator (adjusted HR 0.81, 95% CI 0.62-1.06). We were unable to determine if complete discontinuation differed between the two groups (HR 1.54; 95% CI: 0.97-2.44).

Conclusions: Switching from originator to biosimilar infliximab remains very infrequent in this US sample. We noted a trend for lower risk of missed dose in switchers biosimilar but our results were not precise enough for conclusions regarding relative persistence with biosimilar versus originator. These 'real-world' results may reflect true underlying effects although we cannot rule out residual confounding (e.g. differences in time of originator use or disease duration).

3900 | Persistence in rheumatoid arthritis patients on biosimilar and bio-originator etanercept: A pooled analysis of pan-Canadian cohorts

Cristiano S. Moura[1], Denis Choquette[2], Louis Coupal[2], Orit Schieir[3], Vivian Bykerk[4], Marie-France Valois[5], Gilles Boire[6] and Walter P. Maksymowych[7]

[1]McGill University Health Center, Montreal, QC, Canada; [2]Institut de Rhumatologie de Montréal, Montreal, QC, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]Hospital for Special Surgery, New York, NY; [5]McGill University, Montreal, QC, Canada; [6]University of Sherbrooke, Sherbrooke, QC, Canada; [7]University of Alberta, Edmonton, AB, Canada

Background: Biosimilar etanercept (ETA-B) was recently introduced in Canada but real-world data descriptions of drug persistence (and comparisons with the originator product, ETA-O) are still scarce.

Objectives: To describe and compare persistence of ETA-B and ETA-O in RA.

Methods: We used data from four ongoing, prospective cohorts in Canada: the Canadian Early Arthritis Cohort (CATCH), the Rheumatoid Arthritis Pharmacovigilance Program and Outcomes Research in Therapeutics (RAPPORT), the Early Undifferentiated Polyarthritis (EUPA) cohort, and the RHUMADATA® registry. We studied biologic-naïve and biologic-experienced RA adult initiating ETA-B or ETA-O between Jan. 2015 and Oct. 2019. Switchers from ETA-O to ETA-B (or vice-versa) were included. We assessed persistence of therapy in the first 12 or 24 months, measured as time from therapy initiation (time zero) to discontinuation. Individuals switching between products could contribute further person-time to the new exposure category. Multivariable Cox regression models were performed with each cohort dataset separately, following a common protocol. Model variables included age, sex, comorbidity, past biologic use, and disease duration. After testing for between-study heterogeneity (Higgin's I^2), cohort-estimated hazard ratios (HR) were pooled using random-effects meta-analysis.

Results: We identified 262 episodes of etanercept use (118 ETA-B and 144 ETA-O) from 250 RA patients. Sex distribution (% of female) on the four cohorts ranged from 63% to 73% in the ETA-B group and 67%-77% in the ETA-O group; mean age ranged from 51±15 to 59 ±15 in the ETA-B group and 51±13 to 59±15 in the ETA-O group. Across cohorts, there was considerable variation in RA duration at the time of initiating ETA-B or ETA-O. In the pooled analysis, the HR for discontinuation at 24 months comparing ETA-B to ETA-O was 0.51 (95% confidence interval, CI: 0.26-0.98). The pooled analysis for therapy discontinuation at 12 months adjusted HR in this analysis was 0.82 (95% CI: 0.42-1.60).

Conclusions: Despite wide confidence intervals, the 24-month data suggested potential better persistence with ETA-B versus ETA-O, with a similar trend at 12 months. Some of the observed associations may be related to residual confounding (e.g. disease activity, time-dependent effects of concomitant medications) and/or survivorship bias (in patients transitioning from ETA-O to ETA-B).

3916 | Machine learning coupled with patient reported outcome data to classify & predict RA disease activity: Results from the AWARE trial

Jeffrey R. Curtis[1], Fenglong Xie[1], Shelly Kafka[2] and Shawn Black[1]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Janssen Scientific Affairs, LLC, Horsham, PA

Background: Patient reported outcome (PRO) data have assumed increasing importance in the care of rheumatoid arthritis (RA) patients.

Objectives: Physician-derived disease activity measures such as CDAI remain the most-accepted metrics to assess RA. The possibility that newer, longitudinal PRO might proxy for the CDAI has not been evaluated.

Methods: Setting: Using data from the Comparative and Pragmatic Study of Golimumab IV vs. Infliximab (AWARE), we evaluated RA patients initiating one of these two therapies who started in moderate or high disease activity and remained under observation through 6 months. Interventions: The primary prediction target was CDAI and CDAI disease activity category at Month 6. Outcome measures: Candidate predictors included baseline CDAI, baseline PROs including those from the NIH PROMIS system (e.g. Pain Interference, Fatigue, Physical Function, Sleep Disturbance), and follow up PROs at month 1 and 6 (+-30 days). Data were randomly partitioned into a training (2/3) and test (1/3) datasets. Multiple machine learning (ML) methods (e.g. Gradient Boosting, (XGBoost), RandomForests, SVM, ensemble approaches) and traditional statistics (e.g. LASSO, logistic regression) were used to classify both CDAI, and CDAI disease activity category

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(remission/low vs. moderate/high). Statistical Analysis: Model performance evaluated cross-validated error comparing different ML approaches using the test data.

Results: A total of 388 AWARE patients were analyzed. Of these, the distribution of disease activity by CDAI at month 6 was remission (4.9%), low (26.8%), moderate (31.7%), and high (36.6%). The more optimal analytic approaches were gradient boosting (XG), LASSO and RandomForests, and resulted in c statistics of 0.83 (XG), 0.80 (LASSO) and 0.78 (RF) for the binary outcome. In univariate analysis examining outcomes at 6 months, and depending on which modeling method was used, the most important features included pain intensity, PROMIS measures (social participation, pain interference, pain intensity, physical function), baseline CDAI, and age. Requiring a minimum PPV of 80%, sensitivity ranged from 74-92% (depending on ML method) to identify LDA/remission.

Conclusions: Machine learning methods coupled with longitudinal PRO data appear useful and accurate to classify RA disease activity over time among patients starting a new biologic. This approach has promise to support real-world evidence generation in the circumstance where PRO measures are available but physician-derived disease activity data is yet.

3930 | Variation in definitions of granulocyte colony stimulating factor prophylaxis and patient outcomes: A scoping review of observational studies

Cara L. McDermott[1], Pamala A. Pawloski[2], Prasad Gawade[3], Cynthia Holmes[4], Edward Li[5], Aaron Mendelsohn[6], Gary Yee[7] and Catherine M. Lockhart[1]

[1]Biologics and Biosimilars Collective Intelligence Consortium, Alexandria, VA; [2]HealthPartners Institute, Bloomington, MN; [3]Amgen, Inc, Thousand Oaks, CA; [4]AbbVie, North Chicago, IL; [5]Sandoz, Princeton, NJ; [6]Harvard Pilgrim Health Care Institute, Boston, MA; [7]University of Nebraska Medical Center, Omaha, NE

Background: The uptake of granulocyte colony stimulating factor (G-CSF) biosimilars has started in clinical practice, but limited comparative research exists on safety and effectiveness in real-world settings.

Objectives: To conduct a scoping review to examine exposure and outcome definitions used in observational studies of long and short-acting G-CSFs. Our findings will inform the design of future comparative effectiveness research (CER) with G-CSF products, including biosimilars.

Methods: Our review identified observational studies of G-CSF use in patients with cancer age 18y+, who received myelosuppressive chemotherapy. We included studies in humans, published in English between January 1, 2012 and December 31, 2019 in Medline. This time period was selected to include study populations from 2011 and beyond to allow for adoption of the 2010 European Organization for Research and Treatment of Cancer (EORTC) clinical practice guidelines. We describe definitions, algorithms and analytic methods used in studies to determine and analyze G-CSF prophylaxis, neutropenia, and healthcare utilization.

Results: The initial search strategy identified 385 studies for title review. After reviewing the abstracts of 136 studies, excluding non-observational studies and those outside our timeframe of interest, we included 13 studies in this review. Of included studies, five were conducted in the U.S., four in Europe, two in multiple countries, one in Canada and one in China. Eight (61%) studies were retrospective, using insurance claims or electronic health records and five (39%) were prospective. Studies evaluated solid tumors (38%), non-Hodgkin's lymphoma (8%), or a combination of solid and hematologic malignancies (54%). Definition of G-CSF prophylaxis administration varied between 1 and 7 days after initial chemotherapy receipt. Comparators to G-CSF administration included no G-CSF receipt, biosimilar G-CSF product, or G-CSF receipt outside the study definition of prophylaxis. Studies varied in the definition of neutropenia, e.g. with or without fever, with or without other signs of infection. The most common healthcare utilization evaluated was inpatient hospitalization for neutropenia. No studies reported patient-related quality of life.

Conclusions: To allow for comparisons across studies, future CER should use standardized definitions for primary G-CSF prophylaxis receipt and for neutropenia-related outcomes. Future observational research is needed to evaluate patient quality of life.

4057 | Do labels of drugs with the same mechanism of action describe the same adverse drug reactions? A case study on TNF-alpha inhibitors

Lotte A. Minnema[1,2], Thijs J. Giezen[2,3,4], Jarno Hoekman[1], Toine C.G. Egberts[1,5], Hubert G.M. Leufkens[1] and Helga Gardarsdottir[1,5,6]

[1]Utrecht University, Utrecht, Netherlands; [2]Medicines Evaluation Board, Utrecht, Netherlands; [3]Foundation Pharmacy for Hospitals in Haarlem, Haarlem, Netherlands; [4]Spaarne Gasthuis, Haarlem, Netherlands; [5]University Medical Centre Utrecht, Utrecht, Netherlands; [6]University of Iceland, Reykjavik, Iceland

Background: The drug label is an important information source to guide prescribers and patients on safe drug use. The labels of drugs with the same mechanism of action are expected to show consistency in mechanism of action related adverse drug reactions (ADRs).

Objectives: To assess the consistency in mechanism of action related ADRs described in the label of TNF-α inhibitors.

Methods: We included all TNF-α inhibitors that were approved in the European Union (EU). We extracted, through validated text mining techniques, the ADRs that were described in all versions of the label (section 4.8 of the summary of product characteristics) from date of approval until 31 December 2019. ADRs were characterized using a standard dictionary (Medical Dictionary for Regulatory Activities version 22.1 on the preferred term level). ADRs not related to the mechanism of action (hypersensitivity and administration site reactions) were excluded. We performed Kaplan-Meier analysis to assess the

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

time from first description of an ADR in any of the labels to the first description of the same ADR in the label of another TNF-α inhibitor. The analysis was restricted to TNF-α inhibitors that were approved at the time an ADR was first described. Using a univariable Cox regression analysis, we studied which determinants were associated with an ADR being described in a second label. The following determinants were assessed: a) serious vs. non-serious ADRs; b) important risk vs. non-important risk; and c) ADR first described in the label of the first-in-class product vs. ADR first described in follow-on drug label.

Results: We assessed the labels of five TNF-α inhibitors: adalimumab, certolizumab, etanercept, golimumab, and infliximab. At the end of follow-up, a total of 488 unique ADRs were described in the labels, of which 287 (59%) ADRs were described in one label, 84 (17%) in two, 55 (11%) in three, 32 (7%) in four and 30 (6%) in all five labels. Approximately 5% of the ADRs were described in a second label one year after the ADR was first described in a label. Serious ADRs and ADRs that were classified as important risks were significantly more often described in a second label (HR=3.61 (95%CI: 1.83-7.12), HR=3.01 (95%CI: 1.52-5.94), respectively). Also, ADRs that were first described in the first-in-class product label were significantly more often described in a second label (HR=2.30, 95%CI: 1.28-4.14).

Conclusions: Mechanism of action related ADRs described in the label differ considerably among drugs with the same mechanism of action. This may hamper the provision of safety information to health care professionals and patients.

4167 | Insulin glargine and hypersensitivity reactions as an example of biosimilars pharmacovigilance

Ayad K. Ali and Martin S. Bohm
Eli Lilly and Company, Indianapolis, IN

Background: Hypersensitivity reactions (HSR) are concerns for all biologics and biosimilars, including insulin. In rare circumstances HSR could be serious and life-threatening.

Objectives: To describe a pharmacovigilance approach to monitor HSR for biosimilar insulin glargine (BIG) compared to the original insulin glargine (OIG).

Methods: Adverse event reports submitted to FDA Adverse Event Reporting System (FAERS) between Apr 2000 and Dec 2018 were analyzed. BIG and OIG products were identified by corresponding brand names. HSR were defined by custom narrow and algorithmic structured MedDRA queries (SMQ) of Preferred Terms: 'hypersensitivity'; 'angioedema'; 'anaphylactic reaction'; and 'anaphylactic/anaphylactoid shock conditions'. Multi-item Gamma Poisson Shrinker disproportionality analysis was applied to estimate Empirical Bayes Geometric Mean (EBGM) and corresponding 95%CI (EB05-EB95) as a signal detection metric (EB05≥2.0 denote potential signal that warrants further review). To account for reporting bias due to Weber effect, analyses were restricted to 2 years post-launch for both products (Jan 2017-Dec 2018 for BIG; Apr 2000-Jan 2002 for OIG). To minimize masking effect, adverse event reports submitted for all insulin products—regardless of brand were used as the background during corresponding analysis periods.

Results: A total of 191 and 56 HSR reports were submitted for BIG and OIG, respectively; corresponding to 6.7% and 10% of all adverse events reported during the period for these products, respectively. Serious events accounted for 19.4% (n=37) of HSR reports submitted for BIG and 8.9% (n=5) of HSR reports submitted for OIG. Among all HSR reported for BIG, about 40% (n=77) reported concomitant treatment with other medicinal product, including 20% (n=39) of reports mentioned concurrent treatment with other insulin product (including OIG, n=10) at the time of HSR occurrence. There was no disproportionate reporting of HSR in relation with either product (BIG: EBGM=0.70, EB05-EB95=0.62-0.79; OIG: EBGM=0.67, EB05-EB95=0.53-0.83). Among all insulin products as the background, the disproportional reporting of HSR for insulin glargine was similar between either product (BIG: EBGM=1.30, EB05-EB95=1.15-1.46; OIG: EBGM=1.16, EB05-EB95=0.97-1.38).

Conclusions: There was no difference in reporting of HSR between BIG and OIG. No HSR signal was identified for either product. This pharmacovigilance methodology can be applied to monitor HSR for other biosimilars.

4275 | Trends in formulary coverage of and point-of-sale prices for short-acting filgrastim products

Shelley A. Jazowski[1] and Stacie B. Dusetzina[2]
[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC;* [2]*Vanderbilt University School of Medicine, Nashville, TN*

Background: Adoption of biosimilars has been slower than anticipated in the United States. Commonly cited barriers, including limited formulary coverage and non-competitive prices, have spurred debate around policy solutions and ultimately the future of biosimilar development and utilization.

Objectives: To compare trends in Medicare Part D formulary coverage of and point-of-sale prices for short-acting filgrastim products.

Methods: We used prescription drug formulary and pricing data from the Centers for Medicare and Medicaid Services for Q1-2015 to Q3-2019. We used National Drug Classification and Concept Unique Identifier codes to identify filgrastim (originator biologic), tbo-filgrastim (follow-on biologic approved prior to the implementation of the US biosimilar licensure pathway), filgrastim-sndz (biosimilar approved in Q1-2015) and filgrastim-aafi (biosimilar approved in Q3-2018). For each product, we summarized Medicare Part D formulary coverage and point-of-sales prices (amount paid by beneficiaries and plans to the pharmacy, excluding discounts and rebates).

Results: Prior to filgrastim-sndz entry in Q3-2015, originator filgrastim and tbo-filgrastim were included on 81% and 48% of Medicare Part D formularies, respectively. Filgrastim-sndz was first included on formularies in Q1-2016 (40% coverage). By Q1-2017, formulary inclusion of filgrastim-sndz increased to 45% while coverage of originator filgrastim decreased to 63%. In the quarter following filgrastim-aafi

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

entry (Q1-2019), filgrastim-aafi was included on 9% of formularies, whereas formulary inclusion for originator filgrastim, tbo-filgrastim and filgrastim-sndz was 74%, 51% and 49%, respectively.

Average point-of-sale prices for originator filgrastim were consistently higher than biosimilar and follow-on products. Originator filgrastim's mean price increased from $5,233 in Q1-2016 to $5,430 in Q3-2019, while filgrastim-sndz's average price remained approximately $4,500 during this same period

Conclusions: Formulary coverage of biosimilars lagged behind that of originator filgrastim, while prices for the first biosimilar were comparable to those of the originator product. To increase formulary inclusion, reduce prices and ultimately ensure adoption, Part D plans should consider preferred placement of biosimilars or incorporating biosimilars into existing incentives and cost-savings programs (e.g., Medicare Star Ratings and Shared Savings Programs).

4421 | Changes in patient-reported outcome (pro) scores for nausea and fatigue following weekly methotrexate dose in a real-world sample of RA and PsA patients in the ArthritisPower registry

W. Benjamin Nowell[1], Elaine Karis[2], Kelly Gavigan[1], Laura Stradford[1], Scott Stryker[2], Huifeng Yun[3], Shilpa Venkatachalam[1], Gregory Kricorian[2], Lang Chen[3], Hong Zhao[3], Fenglong Xie[3] and Jeffrey R. Curtis[3]

[1]Global Healthy Living Foundation/CreakyJoints, Upper Nyack, NY; [2]Amgen, Thousand Oaks, CA; [3]University of Alabama at Birmingham, Birmingham, AL

Background: Methotrexate (MTX) is frequently used in patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA). Despite known benefits of MTX, it has potential side effects, including nausea and fatigue, which can be severe and are often temporally related to weekly MTX administration. The combined patient-reported side effects, along with potential long-term toxicity, may make use of MTX more burdensome. Currently, there is a gap in patient-centered studies focusing on patients' experience with MTX.

Objectives: Using self-controlled case series study design, examine fatigue and nausea associated with oral MTX (with or without biologics) in RA/PsA.

Methods: Participants (pts) are members of the ArthritisPower (AP) registry who self-reported RA or PsA and taking MTX for <10 yrs. Each completed a screener and brief online survey. In an ancillary study, pts were asked to complete ≤8 assessments within 6-36 hours ('risk') and 96-144 hours ('control') after a weekly MTX oral dose, for ≤4 weeks. Risk and control windows were selected based on expected temporal relationship between MTX use and peak onset of symptoms. Assessments included PROMIS short forms for same-day Fatigue, Nausea/Vomiting, and Patient Global. Descriptive statistics were conducted using paired t-tests 2-way comparisons. Within-person change in PROMIS scores between risk (1-2 days post MTX) and control (4-6 days post MTX) windows were analyzed using mixed models for repeated measures, stratified by pt reported baseline fatigue or nausea.

Results: As of December 2019, 91 pts participated (76.9% RA and 28.6% PsA) with mean baseline PROMIS Patient Global score (SD) of 39.5 (7.1). Mean age (SD) was 50.9 (12.0) yrs, 84.6% female, 92.3% White, and mean BMI 33.7 (8.8). Mean MTX treatment duration was 2.1 (2.8) yrs. Among pts, 41.8% were on a biologic DMARD and 58.2% on non-biologic DMARDs only. Among pts reporting baseline nausea (n=30, 33.0%), where paired within-week measures were observed (n=64 observations/20 pts), the mean increase in PROMIS Nausea was 4.5 (adj p=0.003) units. Among those reporting baseline fatigue (n=39, 42.9%), where paired within-week measures were observed (n=96 observations/28 pts), the mean increase in PROMIS Fatigue was 4.7 (adj p=0.004) units. In those pts, the proportion of pts with worsened nausea and fatigue with minimally important difference of >5 units was 40.0% (nausea), and 60.7% (fatigue).

Conclusions: One-third or more pts experienced nausea or fatigue shortly after MTX dosing, many of them with clinically meaningful symptoms.

4544 | Risk of preterm delivery and small for gestational age among women with inflammatory bowel disease using TNF alpha inhibitors during pregnancy

Xi Wang[1], Ellen Zimmerman[2], Joshua Brown[1,3], Amie J. Goodin[1,3] and Almut Winterstein[1,3]

[1]College of Pharmacy, University of Florida, Gainesville, FL; [2]College of Medicine, University of Florida, Gainesville, FL; [3]Center for Drug Evaluation and Safety(CoDES), University of Florida, Gainesville, FL

Background: There is limited evidence on the benefit (in controlling disease) and risk (e.g., due to immune-modulatory properties) of TNF-alpha inhibitors (anti-TNFs) use during pregnancy for women with inflammatory bowel disease (IBD).

Objectives: To investigate the association between anti-TNF use during pregnancy and the risk of preterm or small for gestational age (SGA) delivery.

Methods: A retrospective cohort study established from the 1999-2012 Medicaid Analytic eXtract and the 2005-2015 IBM MarketsSan Databases. We included pregnant women with IBD enrolled in insurance plans from 6 months before the last menstrual period through 1 month after delivery and linked infants enrolled for at least 1 month after birth. The exposure of interest was treatment with anti-TNFs (adalimumab, certolizumab pegol, infliximab), or immunomodulators (azathioprine, mercaptopurine, cyclosporine). Preterm and SGA were defined with validated claim-based algorithms. We estimated risk ratios (RRs) after balancing exposure groups with stabilized inverse probability of treatment weights (SIPTW) to control for confounders. To assess the impact of anti-TNFs use during late pregnancy, we used a cox regression model with SIPTW adjustment to assess the hazard ratio (HR) of preterm in exposure to anti-TNFs vs. immunomodulators in the third trimester.

Results: Among 6,045 pregnancies with IBD, 498 (8.2%) were exposed to anti-TNFs, and 398 (5.6%) to immunomodulators during

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pregnancy. Overall, 67 (13.5%) anti-TNFs exposed and 69 (20.1%) immunomodulators exposed infants were preterm births and 13 (2.6%) anti-TNFs exposed and 14 (4.1%) immunomodulators exposed infants were SGA. The adjusted RR for preterm was 0.65 (95% confidence interval (CI), 0.47-0.89) and the adjusted RR for SGA was 0.54 (95% CI, 0.26-1.14). The adjusted HR for preterm risk in the third trimester was 0.49 (95% CI, 0.35 to 0.67).

Conclusions: Use of anti-TNF during pregnancy was associated a decreased risk of preterm among pregnant women with IBD. The current findings also suggest that third trimester use of anti-TNF could decrease the risk of preterm delivery relative to the use of immunomodulators.

4575 | Effect of biosimilar market entry on cost of biologics in the United States: The case of filgrastim

Morgane Mouslim, Caleb Alexander and Jodi Segal
Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: Biosimilars, lower cost, highly similar but inexact copies of referent (brand name) biologics, have been put forth as a promising cost containment strategy for mounting drug prices. However, since their introduction in the United States market, few studies have investigated whether they have been an effective tool in curbing pharmaceutical expenditures with regards to biologic medications. The launch of filgrastim-sndz, the first Food and Drug Administration approved biosimilar, provides a natural experiment with which to empirically evaluate and quantify biosimilar generated cost savings in the United States.

Objectives: To estimate the effect of filgrastim-sndz market entry on cost of filgrastim in the United States.

Methods: This study used a single interrupted time series approach and data from the IBM MarketScan® Commercial Claims and Encounters database to assess the impact of filgrastim-sdnz market entry on cost of filgrastim in the U.S. Study population consisted of outpatient prescription claims for filgrastim, and filgrastim-sndz from January 1, 2014 to December 31, 2017. Our exposure of interest was the September 2015 U.S. launch of filgrastim-sndz. Our primary outcome was the monthly mean reimbursement cost to third party payers (insurers) for filgrastim. Cost was adjusted for inflation using the Consumer Price Index for Medical Care Commodities and was standardized to cost per 480 mcg vial. To the extent that filgrastim-sndz market entry did not translate into immediate market penetration, we used a test of unknow break point to test for an intervention point post filgrastim-sndz launch. Analyses were adjusted for autocorrelation and seasonality

Results: Following filgrastim-sndz launch there was an immediate level decrease in the cost of filgrastim of approximately $5.38 dollars per 480 mcg vial (95% CI, -9.22 to - 1.55; p=0.007) but no significant decrease in monthly cost trend (β= -0.11; 95% CI, -0.61 to -0.38 ; p=0.634). Results of our structural break analysis show a significant discontinuity in utilization of filgrastim 16 months post filgrastim-sndz launch (sup-Wald, 38.25, p<0.001). After this estimated "market penetration intervention point" we observed a significant decrease in the monthly cost trend of a 480-mcg vial of filgrastim (β= -1.22; 95%CI, -2.30 to -0.13, p=0.029).

Conclusions: Among commercially insured patients, filgrastim biosimilar availability led to an immediate decrease in price level and a lagged decrease in price trend for filgrastim. The delay in price trend decrease is likely due to the lag between biosimilar availability and biosimilar adoption.

4583 | Traceability of biosimilar and reference products in adverse drug events reports in Saudi Arabia

Fares Alrubaish, Rayan Alolayet, Muhanad Alharbi, Hamad Alnomay and Fawaz Alharbi
Saudi Food and Drug Authority, Riyadh, Saudi Arabia

Background: Product trade name and batch number are essential elements in reporting Adverse Drug Events (ADEs) of biologics (reference and biosimilar products) due to the variability of biomanufacturing process.

Objectives: To assess the availability of biologics (reference and biosimilar) trade name and batch number in ADE reports on the National Pharmacovigilance Center (NPC) database at the Saudi Food and Drug Authority (SFDA).

Methods: We performed a descriptive analysis of ADE case reports of biosimilars and reference products in Saudi Arabia reported to the NPC by healthcare providers and the public from January 2010 to January 2020. The analysis examined the reporting frequency of the product trade name, batch number, and the type of reporter.

Results: We identified 322 ADE case reports of biosimilars and reference products. The product trade name was only included in 97 (30%) ADE case reports. The majority of case reports (303; 94%) did not include the batch number. 224 (70%) ADE case reports did not specify the reporter type. The remaining cases (98; 30%) were reported by pharmacists.

Conclusions: The analysis demonstrates the need for improving the traceability of biosimilars and reference products in Saudi Arabia. The product trade name and batch number are essential elements in post-marketing safety surveillance of biosimilars and reference medicines.

4586 | Cardiovascular risk in patients receiving ranibizumab therapy for exudative age-related macular degeneration: A nationwide self-controlled case-series study

Ha-Lim Jeon[1], Seong Jun Byun[1], Nicole L. Pratt[2], Janet Sultana[3], Sang Jun Park[4] and Ju-Young Shin[1]
[1]Sungkyunkwan University (SKKU), Suwon, Republic of Korea; [2]University of South Australia, Adelaide, Australia; [3]University of Messina, Messina, Italy; [4]Seoul National University Bundang Hospital, Seongnam, Republic of Korea

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Ranibizumab is a vascular endothelial growth factor (VEGF) inhibitor, which is developed for the treatment of exudative age-related macular degeneration (AMD). Although cardiovascular complications are identified by systemic use of anti-VEGF in oncology, it is still unclear whether intravitreal anti-VEGF injection is associated with the systemic cardiovascular events.

Objectives: To examine the association between ranibizumab use and the risk of stroke and acute myocardial infarction (AMI) using a self-controlled case-series design.

Methods: We identified patients aged ≥45 years who received ranibizumab for exudative age-related macular degeneration (AMD) between January 2009 and December 2015 using the Korean National Health Insurance database. Of these, we selected patients suffering stroke or AMI for the self-controlled case-series. We estimated age-adjusted incidence rate ratios (IRRs) with 95% confidence intervals (CIs) for stroke or AMI by comparing incidence rates of ranibizumab-exposed periods to that of baseline periods using conditional Poisson regression. We also calculated the risks of hemorrhagic and ischemic strokes separately to examine potential differences due to physiological mechanism.

Results: Among 33,134 patients receiving ranibizumab for exudative AMD, 2,397 patients had stroke or AMI; 1,943 had stroke and 762 had AMI. The median duration of exposure was 4.6 (interquartile range [IQR], 2.7-6.2) and median age at first exposure was 76 (IRQ, 70-81). The risk of stroke (IRR=0.83, 95% CI=0.75-0.91) was not increased during overall exposed period compared to baseline period; however, there was a marginally elevated risk in ≥57 days exposed period (IRR=1.14, 95% CI=1.001-1.31). When analyzing by the types of stroke, no increased risk of hemorrhagic (IRR=1.01, 95% CI=0.80-1.26) and ischemic stroke (IRR=0.78, 95% CI=0.71-0.86) was observed during the exposed period, although the risks of ischemic and hemorrhagic stroke were slightly elevated during ≥57 days exposed period (ischemic: IRR=1.15, 95% CI=1.00-1.32; hemorrhagic: IRR=1.26, 95% CI=0.90-1.76). We could not find an association between ranibizumab and AMI.

Conclusions: This study shows ranibizumab intravitreal injections did not increase the overall risk of stroke or AMI. Although the cardiovascular risk in patient with ranibizumab therapy for exudative AMD seems to be low under current good medical practice, continuous monthly use of ranibizumab for high-risk patients should be judged carefully.

4617 | Biosimilar formulations of gonadotropins in a central Italian region: Use patterns and time trends

Alessandro Cesare Rosa

Department of Epidemiology, Asl Roma 1, Lazio Region, Rome, Italy

Background: Gonadotropins (Gona) are hormones that play a central role in the follicular growth (and therefore in the production of oocytes) in women but are also useful in male infertility. Gona used for infertility treatment are available as urinary extracts or recombinants. In 2015, the first biosimilar of follitropin alfa (a recombinant Gona) was authorised in Italy.

Objectives: We aimed to evaluate use patterns, temporal and spatial variations of Gona biosimilar formulations in a central Italian region, accounting for about 6 Million residents.

Methods: From administrative healthcare databases of the Lazio region, we extracted drug claims in the years 2015-2018. Gona formulations were grouped into urinary (u-Gona) and recombinant (r-Gona). Special focus was on biosimilar r-Gona. Use patterns were investigated with respect to characteristics of the patients treated, time trends, type of prescribing physician, and differences among local health units.

Results: For the study period, we retrieved 112,090 Gona dispensations for 51,178 patients. The 9,878 r-Gona biosimilar dispensations (8.8% of all claims, of which 99.5% Bemfola®, and 0.5% Ovaleap®), were mostly referred to women, aged 18-45 years, (85.5% of all patients). Median age was 37 years for women, 38 for men. Since its authorisation, biosimilar r-Gona steadily gained market from 2015 (0,4% of claims) to 2017 (22,7%) followed by a decrease in 2018 (9,1%). Biosimilars claims are more frequent in treating men (32,4%) than women (6,4%). Most biosimilar prescriptions were issued by general practitioners (83.9%), followed by specialists (7.1%) and others. Biosimilar use patterns varied between different local health units (IQR 3.4%-9,1%).

Conclusions: In clinical practice, in the Lazio region, r-Gona biosimilar dispensation account for less than 10% and are mostly prescribed by general practitioners and proportionally more used in treating men. Further investigation is under way.

4750 | Dupilumab and the risk of conjunctivitis and serious infection in patients with atopic dermatitis: A propensity score-matched cohort study

Maria Schneeweiss[1], Seoyoung Kim[1], Sebastian Schneeweiss[1] and Joseph Merola[1]

[1]*Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Background: Dupilumab is a human monoclonal antibody against interleukin (IL)-4 receptor alpha that inhibits signaling of IL-4 and IL-13, and is indicated for use in moderate-severe atopic dermatitis (AD). Dupilumab has been associated with an increased risk of conjunctivitis in trials, yet there is limited real-world data concerning this adverse event.

Objectives: This study compared the 6-month risk of conjunctivitis and serious bacterial and opportunistic infections in patients with AD who initiated dupilumab versus methotrexate (MTX).

Methods: We identified adults and children with AD enrolled in a US commercial health plan who initiated either dupilumab or MTX (i.e., cohort entry), from March 2017 through June 2019. Conjunctivitis, including bacterial and allergic, and serious bacterial and opportunistic infections were identified as study outcomes. Patients were free of any conjunctivitis diagnosis, any autoimmune or chronic

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

inflammatory disease, or other indications for biologic immunomodulating drugs before cohort entry. We computed the 6-month event risks carrying the exposure status at cohort entry forward for the 180 days of follow up. Relative risks of infection and conjunctivitis were computed after 1:1 PS-matching.

Results: Among 1,132,783 patients with AD we identified 2,000 patients who initiated treatment with either dupilumab (n=1,194) or MTX (n=806). PS-matching resulted in 574 pairs of patients who initiated dupilumab and MTX. In comparing patients with AD who initiated dupilumab versus MTX, we found that those who initiated dupilumab had a decreased 6-month risk for serious infections (6.97 vs. 15.68 per 1,000 patients; RR=0.44 [95% CI 0.13-1.44]), and had an increased 6-month risk for any conjunctivitis (76.66 vs. 38.33; RR=2.08 [1.39-3.58]). The 6-month risk of bacterial conjunctivitis requiring antibiotics was RR=1.44 (0.54-3.80), of allergic conjunctivitis was RR=1.51 (0.53-4.26), and of keratoconjunctivitis was RR= 2.85 (1.02-7.95).

Conclusions: In patients with AD who initiated treatment with dupilumab we identified few cases of serious infection showing no indication of an increased 6-month risk with an upper 95% confidence interval of 1.44 when compared to MTX initiators. Dupilumab initiators had twice the risk of developing conjunctivitis compared to MTX consistently across a range of various types of conjunctivitis. This study adds further evidence of no increase in serious bacterial or opportunistic infections and that an increased risk of conjunctivitis needs to be managed in clinical practice.

4807 | Comparability of patients with CIDP using intravenous immunoglobulin in medicaid vs commercial or medicare claims data

J. Bradley Layton[1], Mary E. Ritchey[1], Zhongwen Huang[2] and Colin Anderson-Smits[2]

[1]RTI Health Solutions, Research Triangle Park, NC; [2]Takeda Pharmaceutical Company, Cambridge, MA

Background: Multiple data sources may be required to obtain necessary sample sizes for studies of rare diseases and treatments. While Medicaid, Medicare, and commercial insurance claims data sources are all available in the US, Medicaid programs for patients with low incomes have differences by state in underlying patient case mix, eligibility criteria, and healthcare coverage.

Objectives: To describe the differences in patient characteristics and medication-usage patterns between patients with chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), a rare neurological disorder affecting nerve signal transmission, as identified in Medicaid versus Medicare or commercial insurance.

Methods: Patients with diagnoses of CIDP were identified in Medicaid, Medicare supplementary, and commercial insurance data (2008-2018). Those subsequently initiating treatment with intravenous immunoglobulin (IVIg) were identified through procedure and pharmacy dispensing coding. Demographic and clinical characteristics of patients and patterns of use of IVIg were compared between patients identified in Medicaid and those in other insurance.

Results: Out of 32,090 patients with CIDP diagnoses, 12% were identified in Medicaid, and 88% in Medicare or commercial claims. Medicaid patients were younger (mean age 51.7 vs. 57.8) and more likely to be female (59% vs. 47%). Medicaid patients were more likely to have any of several comorbidities, including asthma, arrythmias, chronic obstructive pulmonary disease, heart failure, diabetes mellitus, hepatitis, hypertension, and renal disorders, but were less likely to have electrodiagnostic/nerve conduction testing. Of those with CIDP, 10% of the Medicaid sample and 13% of the others initiated IVIg treatment. 23% of IVIg initiation was identified in pharmacy claims in Medicaid, while only 10% IVIg initiation in other insurance was. The duration of IVIg use was shorter among those with Medicaid (188 vs. 216 days).

Conclusions: The characteristics and treatment patterns of patients with CIDP identified in Medicaid differed from those identified in other data sources. Medicaid may be a valuable source of information on an important population, but the suitability of its use and availability of critical study variables should be carefully considered in context to the research question before inclusion in multi-database studies of rare diseases. Assessment of differences in demographics, comorbidities, and treatment patterns could aid understanding of whether Medicaid patients would be best suited for studies including long-term outcomes.

4820 | Adverse event profiles of therapies that target the calcitonin gene-related peptide (CGRP) pathway, during the first six months after launch: A real-world data analysis using the FDA adverse events reporting system (FAERS)

Stephen D. Silberstein[1], Shoshana Reshef[2], Joshua M. Cohen[2], Sanjay Gandhi[2], Michael Seminerio[2], Verena Ramirez Campos[2], Yoel Kessler[2], Stephen Thompson[2] and Andrew Blumenfeld[3]

[1]Jefferson Headache Center, Thomas Jefferson University, Philadelphia, PA; [2]Teva Branded Pharmaceutical Products R&D, Inc., West Chester, PA; [3]Headache Center of Southern California, The Neurology Center, Carlsbad, CA

Background: Since May 2018, three medications that target the CGRP pathway have been FDA approved for preventive treatment of migraine: erenumab-aooe, fremanezumab-vfrm, and galcanezumab-gnlm. Post-marketing data indicate medication safety in a real-world setting.

Objectives: To gain insight into the real-world adverse event (AE) profile of CGRP pathway-targeted migraine preventive treatments.

Methods: This retrospective analysis of data from FAERS, the FDA's database for safety surveillance, evaluated AEs spontaneously reported during the first 6 months post-approval of erenumab, fremanezumab, and galcanezumab using FAERS. We evaluated cases in which the product was classified as the "primary suspect" associated with an AE. Reporting rates (RR) were calculated by dividing number of events in each AE category by estimated number of exposed subjects based on de-identified prescription data (IQVIA database) and multiplied by 1,000 to create a rate per 1,000 exposed.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The top ten AE RRs per 1,000 were: erenumab: wrong technique (4.97), constipation (4.90), migraine (4.89), accidental product exposure (4.83), drug ineffective (3.68), headache (3.32), injection-site pain (2.94), nausea (2.94), under-dose (2.55), and fatigue (2.33); fremanezumab: headache (1.27), drug ineffective (1.14), migraine (1.01), nausea (0.91), injection-site pain (0.81), pruritus (0.73), injection-site erythema (0.71), injection-site pruritus (0.63), injection-site rash (0.63), injection-site swelling (0.58); galcanezumab: injection-site pain (4.90), under-dose (3.86), headache (3.07), migraine (2.99), drug ineffective (1.69), injection-site erythema (1.58), injection-site swelling (1.25); injection-site pruritus (1.14), nausea (1.09), and product-dose omission (1.09).

Conclusions: Migraine, headache, or drug ineffective AEs were commonly reported for all three products, as were migraine-associated symptoms and injection-site reactions. Constipation ranked second for erenumab but did not make the top ten AEs for fremanezumab or galcanezumab. Cardiovascular events were not ranked in the top ten for any product.

4829 | Identifying immunoglobulin use in claims data with procedure coding and pharmacy dispensing data

Colin Anderson-Smits[1], Bradley Layton[2], Zhongwen Huang[1] and Mary Beth Ritchey[2]

[1]*Takeda Pharmaceuticals, Cambridge, MA;* [2]*RTI Health Solutions, RTP, NC*

Background: Immunoglobulins (Ig) may be administered intravenously (IVIg) or subcutaneously (SCIg), inpatient, at an infusion center or at home, and some Ig may be self-administered. Differences in administration routes, treatment guidelines, and reimbursement policies may result in Ig use recorded as dispensed pharmacy products or procedures in US claims data. Correctly identifying users of Ig treatments is critical for valid generation of real-world evidence for these products.

Objectives: To describe the relative distribution and characteristics of Ig initiators identified via procedure and pharmacy claims.

Methods: Patients with diagnoses of primary immunodeficiency (PID) or chronic inflammatory demyelinating polyneuropathy (CIDP) were identified in US commercial, Medicare, or Medicaid claims data. Patients with PID initiating IVIg or SCIG and patients with CIDP initiating IVIg were identified at the first recorded claim for an Ig product in inpatient or outpatient procedure coding (i.e., HCPCS) or pharmacy dispensing drug claims (i.e., NDC). Characteristics of Ig initiators were described, stratified by the source of the first Ig claim.

Results: For patients with PID initiating Ig (N=17,931), 9% were first identified through pharmacy claims; those identified in pharmacy claims were more likely to have Medicaid insurance than those identified in procedure claims (30% vs. 17%). The characteristics of pharmacy-identified patients differed from procedure-identified patients, with some characteristics higher among those identified in pharmacy claims (e.g. asthma, 55% vs. 40%), but others were higher among procedure-identified patients (e.g. leukemia, 22% vs. 4%). Among those with CIDP (N=3,975), 11% were first identified through pharmacy claims, and they were more likely to have Medicaid (19% vs. 8%) or Medicare (38% vs. 23%) than those identified through procedure claims. Pharmacy-identified patients generally had similar or higher levels of most comorbidities compared to procedure-identified patients. Procedure-identified Ig were more likely to have some markers of health care screening and utilization, such as blood laboratory tests, in both diseases.

Conclusions: While most Ig initiators were identified in procedure claims, pharmacy dispensing claims are an important source of information about Ig use and identifying initiation of Ig products. There may be key differences in patient populations identified by procedure or pharmacy coding reflective of the payer policies or treatment guidelines across disease areas.

4853 | Agreement between electronic health record and medical claims data for defining exposure to infused biologic treatments in inflammatory bowel disease

Carrie Huisingh and Lani R. Wegrzyn

AbbVie, North Chicago, IL

Background: Electronic health record (EHR) databases provide researchers the opportunity to conduct investigations that are not possible in insurance claims databases. For pharmacoepidemiology studies, accurate classification of medication exposure is critical. Several medications for treatment of advanced inflammatory bowel disease, i.e. Crohn's Disease (CD) and Ulcerative Colitis (UC), are administered by intravenous infusion in a healthcare provider's office. It is not clear how well this EHR-based treatment information correlates with medical claims.

Objectives: To evaluate the agreement of medication exposure information in EHR and medical claims for infused biologics in patients with CD or UC.

Methods: We conducted a retrospective study among patients with linked medical claims in the Optum de-identified Integrated Claims-Clinical database. Separately for CD and UC, index was defined as the first medication administration or procedure code for an infused biologic, and patients were required to have continuous medical and pharmacy insurance coverage for 180 days prior to and after index. The agreement between EHR medication administration and procedure data and medical claims data was determined for 3 biologic treatments (Infliximab, Ustekinumab, and Vedolizumab) using the positive predictive value (PPV) calculated in 30-day and 180-day periods. Secondary analyses included using codes for unclassified biologics to identify potential claims and restricting to patients with an encounter with a Gastroenterologist within 180 days after index.

Results: In CD patients, the 30-day period PPV was 86.0% for Infliximab, 53.5% for Ustekinumab, and 83.6% for Vedolizumab. The 180-day period PPV was 91.3% for Infliximab, 86.0% for Ustekinumab, and 86.9% for Vedolizumab. In UC patients, the 30-day PPV was 86.1% for Infliximab and 88.0% for Vedolizumab. The 180-day period PPV was

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

90.4% for Infliximab and 89.8% for Vedolizumab. Identifying Ustekinumab users with unclassified biologics code improved the PPV. Requiring a follow-up visit with a GI physician did not substantially improve medication exposure classification.

Conclusions: There was high agreement between EHR medication administration and procedure data and medical claims data for infused biologics used in the treatment of inflammatory bowel disease. To maximize the validity of classifying medication exposure with EHR data, researchers may consider using longer periods (180 days) and including unclassified biologics codes for newer drugs.

4861 | Profile of patients with rheumatic diseases and treated at a Brazilian Health System Unit in Belo Horizonte City

Natália Brandão, Marina Morgado, Gerusa Araújo, Juliana Alvares-Teodoro, Francisco Acúrcio and Augusto Afonso Guerra
Federal University of Minas Gerais, Belo Horizonte, Brazil

Background: Rheumatic diseases are chronic inflammatory diseases, autoimmune, associated with joint destruction. Biological drugs are often used to treat these diseases.

Objectives: Retrospective analysis of demographic, clinical and drug utilization characteristics of patients diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PA) or ankylosing spondylitis (AS), undergoing outpatient follow-up and receiving biological drugs by the Brazilian Public Health System (SUS) unit in Belo Horizonte city.

Methods: Cross-sectional study focusing on secondary data of patients attended regularly at the SUS unit through the request for medication completed by the doctor. The categorical variables were described by means of the distribution of frequencies and the continuous variables by means of mean and standard deviation at baseline.

Results: 426 patients were evaluated and 59% used previously biologics. The mean age of 306 RA patients was 56 years and 87.5% were women. The mean disease duration was 34 months. 60% of the patients had affection in more than 10 joints and 76.5% scored 5 or more points in the ACR/EULAR criteria. 51.8% had rheumatoid factor or anti-CCP positive in high titers. 99.7% had rheumatoid vasculitis and 97% rheumatoid lung disease. 95% had high or moderate disease activity, according to the DAS-28. 42% requested tofacitinib, 24% certolizumab pegol and 10% abatacept. The mean age of 65 PA patients was 54 years and 61.5% were women. The mean disease duration was 26 months. All patients had inflammatory joint disease, 89.2% with peripheral involvement, 16.9% enthesitis or dactylitis and 15.4% with axial involvement. 75.4% had current psoriasis, 36.9% psoriatic nail dystrophy, 21.5% current dactylitis and 23.1% radiographic evidence of proliferation bone (CASPAR Classification). Regarding the MDA, 31.3% met 5 or more criteria. 83% requested secuquinumab, 8% golimumab and 5% adalimumab. 65% used previously NSAIDS drugs. The mean age of 58 AS patients was 48 years and 53.4% were women. The mean disease duration was 26 months. 71% had peripheral arthritis and 29% had inflammatory low back pain and enthesitis. As for the ASAS criteria, 98.4% had inflammatory low back pain for at least 3 months, disease onset was up to 45 years and 96.8% had sacroiliitis on imaging tests. 45% requested secuquinumab, 21% golimumab and 19% certolizumab pegol.

Conclusions: The results showed that patients with rheumatic diseases who requested biological drugs in SUS presented high disease activity. This knowledge may support the development of public policies to improve the access of the biological drugs.

5008 | The adherence patterns among patients using infliximab bio-originator and biosimilar

Joseph C. Alanaeme[1], Sarvesh Sujith[1], Jeffrey R. Curtis[1] and Huifeng Yun[1]
[1]*University of Alabama at Birmingham, Birmingham, AL*

Background: Infliximab (INF) biosimilar was approved for multiple indications in U.S. in 2016. Although clinical trials have demonstrated that switching from infliximab bio-originator to its biosimilar is safe with no significant loss of efficacy, there are limited real-world data comparing their utilization and adherence patterns.

Objectives: We evaluated medication adherence among INF biosimilar users and compared them to INF bio-originator users using national administrative data, 2014-2018.

Methods: We established 4 cohorts among patients who had at least one administration or pharmacy claim for INF bio-originator or biosimilar in 2017 Truven Marketscan data, including INF biosimilar naïve users, INF biosimilar prevalent users, INF bio-originator naïve users, and INF bio-originator prevalent users. We evaluate the prior use of INF and other biologics using all available data in 2014-2017 prior to the first INF administration in 2017 (index date). The INF naïve users were defined as no prior use of INF bio-originator or INF biosimilar, whereas prevalent users had any prior use of bio-originator INF but no prior INF biosimilar use. Eligible patients were ≥18 years of age, continuously enrolled with full coverage from 2014 and through follow up. Follow-up started on the index date and ended on the earliest date of death, loss of coverage, or 12/31/2018. For patients who had at least 12 or 18 months of follow-up time, we calculated their proportion of days covered (PDC) at 12 or 18 months. Ongoing analyses are adjusting for important patient characteristics that differ across cohorts.

Results: We identified 96 INF biosimilar naïve users, 223 INF biosimilar prevalent users, 2,149 INF bio-originator naïve users, and 10,970 INF bio-originator prevalent users. The proportion of other biologic use prior to index date and demographic characteristics are similar across different cohorts with mean age of 45 and 60% females. Among patients who had >=12m of follow-up, 43% INF biosimilar naive users, 41.5% INF biosimilar prevalent users, 52% INF bio-originator naïve users and 73% INF bio-originator prevalent users continued to be adherent (>80%) at 12 months. Among patients who had >=18m of follow-up, 48%, 36%, 41%, and 64% user continued to be adherent at 18 months respectively.

Conclusions: The adherence patterns were similar among INF biosimilar naïve, INF biosimilar prevalent, and INF bio-originator naïve users, and the INF bio-originator prevalent users had the highest

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

adherence at 12 or 18 months of follow-up. However, further studies with large sample size are needed to evaluate the adherence and the cost of INF biosimilar users.

5035 | Real-world evidence of the risk of neutropenia among patients treated with filgrastim

Elnara Fazio-Eynullayeva
TriNetX, Inc., Cambridge, MA

Background: As of February 12, 2020, 25 biosimilars referencing nine originator biologics have been approved for use in the United States. Filgrastim is a biologic drug used to treat patients with low neutrophil count. This study builds on previous research in comparing filgrastim originator biologic with stand-alone alternative biologic tbo-filgrastim and biosimilar filgrastim-sndz using real-world data.
Objectives: The aim of this study was to compare the risk of neutropenia in patients on chemotherapy treated with filgrastim, tbo-filgrastim and filgrastim-sndz.
Methods: Chemotherapy-treated patients were identified in a US-based EMR network (>55.8 million patients). Patients with evidence of neutropenia prior to index filgrastim biologic/biosimilar use were excluded. Three separate comparison analyses were conducted: patients treated with filgrastim were compared to patients treated with tbo-filgrastim; those treated with filgrastim were compared with those treated with filgrastim-sndz; and tbo-filgrastim cohort was compared to the filgrastim-sndz cohort. All comparisons were adjusted for baseline confounders using a 1:1 greedy nearest neighbor matching propensity score model. Risk ratios, 95% confidence intervals, and Kaplan-Meier survival curves were calculated. Patient characteristics were defined by ICD, CPT, LOINC, and RxNorm terminology.
Results: The standardized mean difference for all baseline characteristics after propensity score matching was less than 10%. After matching, there were 520 patients in each, filgrastim and filgrastim-sndz cohorts. The risk of neutropenia was higher in filgrastim cohort (N=157) than in filgrastim-sndz cohort (N=91), RR=1.73 [1.37, 2.17]. Differences in the risk of neutropenia between filgrastim and tbo-filgrastim, as well as between filgrastim-sndz and tbo-filgrastim were found to not be statistically significant.
Conclusions: This analysis found that compared with filgrastim-sndz, there was a higher risk in the filgrastim cohort for incidence of neutropenia. No significant differences in the risk of neutropenia were observed in the other two comparisons.

5120 | Seasonal differences in omalizumab utilization among persons with asthma and allergic rhinitis in the United States

Ayobami Akenroye, Kayte Andersen, Corinne Keet, Jodi Segal and Caleb Alexander
Johns Hopkins University, Baltimore, MD

Background: Seasonal variations in asthma morbidity and mortality have been well documented, with disease worsening due to viral respiratory infections in the winter and environmental allergens in the fall. Omalizumab is a monoclonal antibody approved for severe allergic asthma in the case of inadequate control with inhaled corticosteroids. Thus, seasonal variations in asthmatic disease activity may be reflected as treatment escalation to omalizumab.
Objectives: To describe seasonal differences in the initiation, adherence, and persistence to omalizumab in the United States from 2011 to 2017.
Methods: Longitudinal retrospective cohort analysis using the IBM MarketScan® Commercial Claims and Encounters Database. We included patients with concomitant diagnoses of asthma and allergic rhinitis and at least 1 claim for omalizumab between 2011 and 2017, using a 1-year look-back period to ascertain new user status. We used date of dispensation and days of supply to define continuous omalizumab use. Linear regression (adjusted for age, sex, days supply, copay, insurance type & region) was used to compare percent differences in the proportion of days covered (PDC) between seasons with 95% confidence intervals (95% CI). Time to discontinuation, defined as a gap of 180 days or more between claims given the monthly dosing administration, was assessed using hazard ratios (HR) and 95% CI from Cox proportional hazards models, adjusted for the variables listed above.
Results: A total of 7,535 individuals were included, with a mean age of 43 years (standard deviation, SD 15) and 65% were females. A majority of omalizumab initiations (41%) were in the winter, with similar rates for the other seasons (spring 19%, summer 18%, fall 17%). In multivariable analyses, persons who initiated in the winter (-16%, 95% CI -10 to -21%), spring (-16%, 95% CI -10 to -22%) and summer (-12%, 95% CI -6 to -18%) had significantly lower PDC than persons who initiated in the fall. The average duration of use was 2.8 years (1.6 years). Persistence was significantly shorter for prescriptions initiated in the winter (HR=1.74, 95% CI 1.37-2.21) and spring (HR=1.56, 95% CI 1.20-2.01) compared to fall initiations, but not summer (HR=1.27, 95% CI 0.96-1.69).
Conclusions: There is seasonal variation in omalizumab initiation, adherence and persistence, which may reflect confounding by indication rather than true differences in omalizumab effectiveness. Future studies examining adherence to omalizumab and effectiveness should account for possible underlying seasonal differences.

5124 | Use of monoclonal antibodies for asthma in the United States, 2003-2019

Ayobami Akenroye, Jamie Heyward, Corinne Keet and Caleb Alexander
Johns Hopkins University, Baltimore, MD

Background: Little is known about the use of the monoclonal antibodies approved for the treatment of asthma in the US.
Objectives: We quantified trends and patterns of utilization of these biologics in the US.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We used the IQVIA National Disease and Therapeutic Index™ (NDTI), a nationally representative survey of over 4000 office-based physicians in the US. We focused on ambulatory visits where asthma was diagnosed and treated with one or more of the biologics ("treatment visit").

Results: From 2003 to 2019, annual asthma-related visits plateaued between 12 and 14 million. Biologic treatment visits ranged from 0.4% of 14,167,830 asthma-related visits in 2004, the first full year with a biologic available, to 1.1% of 14,343,305 visits in 2018, the most recent year with complete data [trend, p=0.03]. Omalizumab was the most used biologic, accounting for 53% of the visits in 2018, followed by mepolizumab (26%), benralizumab (21%), and reslizumab (0.7%). Data on dupilumab use is limited given its recent introduction. Of these biologic treatment visits, 58% were female, 48.6% 40-59 years of age, 21% 60-74 years, 17% 20-39, 9% 6-19, and <5% ≥75 years of age. 66.8% were white, 14% black, and 12% Hispanic. These visits were mostly to allergists [55%] and pulmonologists [32%]. Internists, family practitioners, and pediatricians accounted for 9%, 2%, and 0.5% of these visits respectively.

Conclusions: There is an overall increasing trend in the use of biologics for asthma with omalizumab remaining the most commonly prescribed biologic for asthma. Use of mepolizumab and benralizumab is increasing.

5141 | Tumor necrosis factor alpha-inhibitor (TNFα-I) use and hip fracture in United States (US) veterans with rheumatoid arthritis (RA)

Sarah Homann, Carlos Grijalva, S. Bobo Tanner and James Morrow
Vanderbilt University Medical Center, Nashville, TN

Background: Patients with RA have a greater risk of sustaining a hip fracture than those without. Though some studies have reported beneficial effects of TNFα-I on bone health in patients with RA, whether use of TNFα-I decreases the risk of hip fractures remains unclear. Prior work on this subject have included predominantly female populations.

Objectives: To determine whether use of TNFα-I decreases the risk of hip fractures compared with use of non-biologic disease modifying anti-rheumatic drugs (DMARDs) in US Veterans with RA.

Methods: Using national Veterans' Affairs (VA) data linked to Medicare files from 2000-2017, a retrospective cohort of RA patients was assembled. RA was identified using a validated algorithm. Veterans with prior hip fracture, cancer, and serious organ disease identified during the baseline period were excluded. Cohort members were followed until development of exclusion criteria, hip fracture, leaving VA, enrollment in Medicare Advantage or death. Using this cohort, a nested case-control study was implemented with cases of incident hip fractures identified using an adapted validated algorithm. Incidence density sampling was used to select up to 20 at-risk controls per case on the date of the fracture (index date). Controls were matched to cases on age, sex, VA region, and time since cohort entry. Pharmacy data were used to assess DMARD exposure in the two years preceding the index date. Cases and controls were classified into mutually exclusive exposure categories: non-biologic DMARD users (ref.), TNFα-I biologic DMARD users, non-TNFα-I biologic DMARD users, and others. Multiple imputation with chained equations was used to impute missing values. Multivariable conditional logistic regression was used to assess the association between medication exposure and the risk of hip fracture, accounting for covariates.

Results: During follow-up, 496 hip fracture cases and 8917 matched controls were identified. The proportion of male cases was 93%, with median age of 76 years. In multivariable analyses accounting for relevant covariates, hip fracture cases had similar odds of exposure to TNFα-I compared with controls (aOR: 1.08 [95% CI, 0.73 - 1.60]). Factors associated with hip fractures in the multivariable regression included the use of benzodiazepines, opioid analgesics, SSRIs, and inhibitors of bone resorption. Use of thiazide diuretics was associated with a lower risk of fracture.

Conclusions: In this preliminary assessment, use of TNFα-I was not associated with a decreased risk of hip fractures compared with use of non-biologic DMARDs among Veterans with RA.

Disease Epidemiology/Clinical Course -> Cancer

129 | Screening for potential prescription drug effects on prognosis of localized colorectal cancer

Anne Katrine Duun-Henriksen[1], Klaus K. Andersen[1], Irene Petersen[2], Henrik Toft Sørensen[3], Anssi Auvinen[4], Laurel A. Habel[5], Jesper Hallas[6], Anton Pottegård[6], Jiri Bartek[1], Søren Friis[1] and Christian Dehlendorff[1]
[1]Danish Cancer Society Research Centre, Copenhagen, Denmark; [2]University College London, London, United Kingdom; [3]Aarhus University Hospital, Aarhus, Denmark; [4]University of Tampere, Tampere, Finland; [5]Kaiser Permanente, Oakland, CA; [6]University of Southern Denmark, Odense, Denmark

Background: Identification of harmful or beneficial effects of drugs on cancer prognosis has inspired efforts in drug safety and drug repurposing for cancer treatment. Large registries are excellent data resources for screening for potential candidate drugs.

Objectives: In this study, we present a framework for screening the potential effects of prescription drugs on cancer prognosis based on the Danish nationwide health registries, illustrated by localized colorectal cancer (CRC) patients.

Methods: We used the National Cancer Registry to identify all one-year survivors of localized CRC in the period 2002-2015 and retrieved their prescription history from the Danish Prescription Registry. We followed the patients from one year after diagnosis up to 5 years after diagnosis. The framework consists of two estimation steps and three evaluation criteria for each unique drug class (4^{th} ATC level). First, inverse probability (IP)-weighted hazard ratios (HRs) for overall and cancer-specific death from Cox models were used to compare drug users vs. nonusers. Stabilized IP weights were estimated from a

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

logistic regression model with sex, age at diagnosis, period of diagnosis, marital status, income, and cancer treatment included as covariates. Secondly, five-year survival probabilities for users and nonusers were estimated using the IP-weighted Kaplan-Meier (KM) estimator. For each drug class, use was defined as redeeming at least one prescription within the first year after diagnosis. Drug classes with less than 100 users were not considered. For each drug class, the analyses were restricted to individuals with no prescriptions within the last year prior to diagnosis. Drug classes fulfilling all of the following three criteria were defined as potential signals: Criteria 1: The HR for overall death was >1.5 or <0.67 or the confidence interval did not overlap 0.83-1.2. Criteria 2: The HR for cancer-specific death was as least the magnitude as the HR for overall death. Criteria 3: The IP-weighted KM five-year survival estimates for users and nonusers was statistically significantly different at a 5% significance level.

Results: In total, 15,274 one-year survivors of CRC filled prescriptions of 941 unique drugs in 412 unique drug classes during the first year after cancer diagnosis. Out of the 412 drug classes, 94 were eligible for screening. From the evaluation, we identified seven drug classes with a potential effect on the prognosis of one-year survivors of CRC.

Conclusions: Applied on localized CRC patients, our proposed screening framework identified seven potential candidates among 94 drug classes for further investigation.

2371 | Venous thromboembolism and risk of cancer in users of low-dose aspirin: A Danish population-based cohort study

Frederikke Schønfeldt Troelsen[1], David Nagy[1], Nils Skajaa[1], Dóra Körmendiné Farkas[1], Rune Erichsen[1,2] and Henrik Toft Sørensen[1]
[1]Aarhus University Hospital, Aarhus N, Denmark; [2]Randers Regional Hospital, Randers, Denmark

Background: Long-term use of low-dose aspirin has been associated with a reduced risk of several cancers. Venous thromboembolism (VTE) is a marker of increased cancer risk; however, it remains unknown whether VTE is a marker of occult cancer in users of low-dose aspirin.

Objectives: To investigate the risk of cancer subsequent to VTE among users of low-dose aspirin.

Methods: We performed a population-based cohort study in Denmark, linking prospectively collected, individual-level data from existing Danish health registries during 2006-2017. We identified all patients with a first-time hospital-based diagnosis of VTE who also redeemed a prescription for low-dose aspirin within 90 days prior to the date of their first-time VTE. We defined new use of aspirin as first-time prescription within one year prior to the VTE diagnosis and current use as first-time prescription more than one year prior to the VTE diagnosis. We computed absolute risks of cancer, treating death as a competing risk, and age-, sex-, and calendar-period standardized incidence ratios (SIRs) by comparing the observed cancer incidence among aspirin users with the expected risk of cancer based on national cancer incidence during the study period.

Results: We followed 8,891 users of aspirin with VTE for a median of 2,5 years (interquartile range (IQR): 0.6-5.3 years). Current users comprised 87% of the study population. The median age at VTE diagnosis was 77 years (IQR: 68-84 years) for current and 68 years (IQR: 58-78) for new users, respectively. We observed 1,159 cancers among current users of aspirin. The one-year absolute risk of cancer was 7.0% (95% confidence interval [CI]: 6.5-7.6) with a corresponding SIR of 3.0 (95% CI: 2.8-3.3). The SIR decreased to 1.1 (95% CI: 1.0-1.2) during the subsequent years of follow-up. We observed 182 cancers among new aspirin users yielding an absolute risk of 6.1% (95% CI: 4.8-7.6) during the first year of follow-up. The SIRs were 3.4 (95% CI: 2.6-4.3) and 1.2 (95% CI: 1.0-1.5) after one and more than one year of follow-up, respectively.

Conclusions: VTE might be a harbinger of cancer even in users of low-dose aspirin regardless of treatment duration.

2376 | Antidepressant dispensing among women with breast cancer, United States, 2001-2018

Jihye Park, Sara Dejene, Sophie E. Mayer, Alan Kinlaw, Hazel B. Nichols, Michele Jonsson-Funk, Virginia Pate, Eliza M. Park, Katherine E. Reeder-Hayes and Jennifer L. Lund
University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Breast cancer is the most common cancer among women in the US. In women with early breast cancer, prevalence of clinically significant depression or anxiety symptoms is twice as many than seen in the general female population, and antidepressant (AD) use is common in this population.

Objectives: To provide an updated summary of patterns of AD dispensing among women with breast cancer diagnosis using a sample of US commercial health insurance claims data, 2001-2018.

Methods: Using the MarketScan claims databases from 2001 to 2018, we identified women aged 18-64 with at least one breast cancer diagnosis code. Women were eligible if they had at least one-year of continuous enrollment pre- and post-breast cancer diagnosis date (index date). A woman was classified as an AD user if she filled at least one prescription at any point within one year of the index date. Descriptive statistics were used to summarize the distribution and trend of AD dispensing. The prevalence of psychiatric diagnosis was determined using the diagnosis codes of depression, anxiety disorder, and adjustment disorder.

Results: Overall, 176,867 women with a diagnosis of breast cancer with a minimum one-year post-diagnosis were identified (median=2.9, IQR=1.8-3.0 years). During the first year after breast cancer diagnosis, 58,205 women (32.9%) had at least one prescription fill for an AD (median time to first fill=45 [IQR=17-121] days). While there was some fluctuation, an overall decrease from 33.8% to 31.1% was observed in the proportion of one-year post-diagnosis AD users between 2001 and 2009, whereas there was a steady increase between 2010 and 2018 from 32.0% to 33.4%. Of all ADs, selective serotonin reuptake inhibitors (SSRIs) were the most common class

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

that was first filled after diagnosis date (49.1%), followed by serotonin and norepinephrine reuptake inhibitors (SNRIs; 26.6%), and tricyclic antidepressants (6.9%). When assessing the trend of first fill after diagnosis by drug class among AD users, there was an observed decline in SSRI prescription fills from 51.7% to 46.3%, whereas an observed increase in SNRI prescription fills from 18.5% to 37.0%. Among all women in the cohort, 47,021 (26.6%) had at least one psychiatric diagnosis at any point prior to and during the first year after index date.

Conclusions: In a population of commercially-insured women with breast cancer diagnosis, nearly 33% had at least one prescription fill for an AD during one-year post-diagnosis. Understanding patterns of AD discontinuation and co-prescription with cancer therapy can inform pharmacologic management of depression and anxiety disorders in women with breast cancer.

2378 | Deriving the European Leukemia Net (ELN) risk categorisation in acute myeloid leukemia (AML) patients in a real-world data source

Tao Xu[1], Ana Ferro[2], Felipe Castro[1], Anne-Marie Meyer[1], Bruno Medeiros[3], Tarec Christoffer El Galaly[1] and Evelyn M. Flahavan[2]
[1]Hoffmann-La Roche, Basel, Switzerland; [2]Roche Products Limited, Welwyn Garden City, United Kingdom; [3]Genentec Inc., South San Francisco, CA

Background: ELN risk categorization is key for diagnosis and management of AML. It is based on cytogenetics in combination with specific recurrent molecular mutations. However, the assignment of patients to ELN risk groups using real-world data (RWD) can be limited by data availability and timing of test results.

Objectives: 1) To assess availability of ELN data elements captured in routine clinical practice in an electronic health record (EHR) database, 2) to derive a modified ELN stratification in AML patients based on minimum available variables and 3) describe overall survival (OS) by assigned risk group.

Methods: This retrospective cohort study included patients from the Flatiron Health EHR-derived de-identified database, diagnosed with AML between 2014 and 2019 in the Flatiron Health network which is predominantly community oncology clinics. The database contains demographic and clinical data curated via technology-enabled abstraction. Cytogenetic and molecular testing results were abstracted from unstructured data. We implemented an algorithm based on the 2017 ELN definition, while accounting for data completeness. Median OS (mOS) from the time of 1L treatment (tx) was evaluated across risk groups.

Results: Of 815 AML patients, 700 patients had 1st line (1L) tx information available. Of these, 589 had ELN markers tested pre-1L tx. Cytogenetic markers such as t(8;21), were tested in 552 (78.9%) of the patients pre-1L tx. Molecular markers, such as RUNX1 or TP53, were more commonly tested in recent years e.g. TP53 was tested in 7.2% of the patients in 2014 and 38.6% in 2019. Overall, the test prevalence was <50% for these markers. Cytogenetic tests still dominated the genetic profiling techniques used (~ 80%), however, increased use of next generation sequencing (NGS) was observed: 7.2% in 2014, 50% in 2019.

The algorithm identified AML patients with favorable N=94, mOS 35.6 months (95% CI 26.9, NA), intermediate N=225, mOS 12.5 (95% CI 10.9, 18.4) and adverse N=179, mOS 9.1 (95% CI 7.9, 10.5) risk. Ninety-one patients had insufficient markers for risk categorization and were assigned to "unknown" with mOS 13.9 months (95% CI 12.2, NA), and had slightly better mOS than the patients with no ELN markers tested N=111, mOS 10.2 months (95% CI 5.8, 18.2). Results were robust when restricted to patients receiving intensive tx.

Conclusions: Increased use of NGS testing was observed in patients with AML. EHR-derived data can be used to define risk groups based on the 2017 ELN criteria. We demonstrated the stratification of patients and outcomes with the derived ELN algorithm.

2425 | Serum lipid trajectories in the years before a lymphoma diagnosis

Joan Fortuny[1], Estel Plana[1] and James A. Kaye[2]
[1]RTI-Health Solutions, Barcelona, Spain; [2]RTI-Health Solutions, Waltham, MA

Background: Serum cholesterol levels are known to be low in patients newly diagnosed with a lymphoma. Only one study has examined the trajectory of cholesterol levels in the years before a lymphoma diagnosis.

Objectives: To describe the trajectories of lipid serum levels (total, low and high-density lipoprotein cholesterol and triglycerides) in the years before a diagnosis of lymphoma in a European population.

Methods: We conducted a case-control study on patients with a lymphoma diagnosed between 2000 and 2017. Up to 5 noncancer controls per case were matched on practice, sex, calendar year, and age at lymphoma diagnosis date or an equivalent date among the controls (index date). Study participants were aged ≥ 40 years at index date; had no evidence of another cancer, HIV infection, or organ transplantation before or on the index date; and had ≥ 1 cholesterol measurement before the index date and before the first prescription of a hypolipidemic drug. General practitioner and hospital data from the Clinical Practice Research Datalink in the United Kingdom were used. Multilevel, multivariable linear longitudinal models were fit to examine the trajectories of serum lipid levels in the years before the index date with time since index date, case status, and confounders in the model.

Results: During the study period, 3,161,492 patients had a valid cholesterol measurement. Among these, 11,969 cases of non-Hodgkin lymphoma and 473 of Hodgkin lymphoma met the study's inclusion and exclusion criteria. Controls were selected for non-Hodgkin lymphoma and Hodgkin lymphoma cases (59,537 and 2,357, respectively). The most common subtypes of lymphoma were plasma cell neoplasm, chronic lymphocytic leukemia, and diffuse large B cell lymphoma. For all lymphoma types, crude mean cholesterol levels in the

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

years before index date was lower in cases than in controls. For most lymphoma subtypes, the adjusted cholesterol levels showed a more pronounced decrease in the 4 years before diagnosis. On the other hand, triglycerides levels were not clearly related to case status. Results remained similar when restricting to patients who had never used any hypolipidemic drug and had ≥ 1 measure of cholesterol within 1 year before index date.

Conclusions: This research is the first to replicate a similar study conducted in the United States, while more thoroughly adjusting for potential confounders. The different behavior of cholesterol and triglycerides, described here for the first time, offers insight into the role of lipids in lymphomagenesis. The study suggests the potential role of cholesterol as a biomarker for lymphoma in the years prior to its diagnosis.

2452 | End-of-life anticancer treatment: A nationwide registry-based study

Thea O. Mattsson[1], Anton Pottegård[2], Trine L. Jørgensen[1], Anders Green[1,2] and Mette Bliddal[1,2]

[1]*Odense University Hospital, Odense, Denmark*; [2]*University of Southern Denmark, Odense, Denmark*

Background: Anticancer treatments near the end of a patient's life should generally be avoided, as it leaves the patient with no significant anticancer effect but increases the risk of severe side effects. Reports of the frequency of end-of-life treatment including chemotherapy vary markedly.

Objectives: To describe the magnitude of all anticancer end-of-life treatment in Denmark and to identify subpopulations of patients more likely to receive anticancer treatment at the end of their lives.

Methods: Using the Danish national health registers, we performed a nationwide cohort study identifying all deceased cancer patients (≥18 year of age) during 2010-2015 with 1) a diagnosis of a solid tumor defined by ICD10 codes, 2) a clinical oncology contact within 12 months prior to death, and 3) and cancer listed as their primary cause of death. Use of any anticancer treatment in the last 30 days of life was categorised as end-of-life treatment. We used logistic regression models to estimate odds ratios (OR) with 95% confidence intervals (CI) for receiving end-of-life treatment according to sex, age group, cancer group, Charlson Comorbidity Index (CCI), and time since diagnosis.

Results: We identified 42,277 patients (mean age 70 years), of whom 15.9% received end-of-life anticancer treatment. The probability of receiving end-of-life treatment did not change over the study period (p-value 0.09). Chemotherapy alone was the most frequent treatment accounting for 78% of all end-of-life treatments in 2010 decreasing to 71% in 2015. In contrast, immunotherapy and hormone/anti hormone both used as single and combination therapy increased during the study period. Patient dying with breast cancer had the highest frequency of end-of-life treatment (23%), followed malignant melanoma (21%) and prostate cancer (18%). Protective factors for end-of-life treatment were female sex (OR 0.91, 95% CI 0.86-0.97), older age (OR 90+ years 0.10, 95% CI 0.07-0.16 and 75-89 years 0.32, 95% CI 0.27-0.38 compared to 18-44 years), high comorbidity according to CCI (OR CCI 3+ 0.82, 95% CI 0.76-0.88 compared to 0), and being diagnosed >6 months prior to death (OR diagnosed 1-5 years prior to death 0.53, 95% CI 0.50-0.57).

Conclusions: In this nationwide Danish sample of cancer deaths, we found a stable overall rate at 15.9% of receiving anticancer treatment one month prior to death. During the period, a decreasing use of chemotherapy was out-balanced with an increasing use of immunotherapies and targeted treatments. Although, some end-of-life treatment is unavoidable, further research is needed to assess if the frequency of treatment during this period of life reflects inappropriate use.

2469 | Biliary tract cancer (BTC) epidemiology in the United States

Huifen Wang, Binbing Yu and Katherine Baria

AstraZeneca Pharmaceuticals, Gaithersburg, MD

Background: BTC is a rare diagnosis in the US (~8000 people annually) but represents a high disease burden due to late diagnosis, poor prognosis, and limited treatment options. Monitoring the epidemiology of BTC will inform public health management and development of clinical programs and research.

Objectives: Evaluation of BTC incidence, prevalence, mortality and survival rates (SR) using the latest data from SEER and NPCR databases.

Methods: Data (2001-2015) were assessed by age, gender, race/ethnicity (White [W]; White, Hispanics [H]; Black [B]; Asian/Pacific Islander [A/PI]; American Indian/Alaska Native [AI/AN]); and anatomic site (extrahepatic cholangiocarcinoma [ECC], intrahepatic cholangiocarcinoma [ICC], gall bladder cancer [GBC], and ampulla of Vater cancer [AVC]). Incidence was reported as age-standardized rate (ASR; per 100,000 person-yrs) using the 2000 US standard population. Estimates of annual percent changes (APC) were calculated using the weighted least squares method.

Results: ASR for BTC in the US was 5.04. Incidence was slightly higher in males vs females (M, ASR = 5.31; F, ASR = 4.85), and was consistent across most subtypes; although females had a higher incidence of GBC (ASR = 1.92; M, ASR = 1.14). Using incidence of W ethnicity as a reference value (ASR = 4.64), H and A/PI have higher incidence rates (incidence rate ratio = 1.65 and 1.45, respectively). During the survey period, total incidence of BTC increased significantly (APC = 1.76). The highest increase was reported for ICC (APC = 6.65). Overall mortality ASR for patients (pts) with BTC was 3.40. H, A/PI, and AI/AN had higher mortality rates (mortality rate ratio = 1.36, 1.22, and 1.32, respectively) when using W as reference (ASR = 3.25). The 5-yr SR for BTC is 15.2%; all subtypes had a consistent rate (GBC = 18%; ICC = 8.5%; ECC = 9.1%), except AVC (34.5%). SRs among ethnic groups were also largely consistent with the overall, with B having the lowest SR (13.8%) and H the highest (16.6%). While the 5-yr SR is low for BTC overall, it is extremely low for pts with

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

distant disease (3.0%), compared with regional (19.1%) or localized disease (31.5%). The 10-yr prevalence for BTC is 10.8 per 100,000.

Conclusions: Incidence of BTC, particularly ICC, has increased over the last decade and the 5-yr SR for BTC remains low. Discrepancies among race/ethnicity groups may reflect socio-economic and health care access differences. These data underscore the serious unmet need among pts with BTC. Public health efforts should be applied to raising awareness of the growing BTC population and integrating novel therapy options for BTC pts.

2572 | Risk and prognosis of cancer after acute kidney injury

Christian Fynbo Christiansen[1], Dóra K. Farkas[1], Jon P. Fryzek[1,2], Paola Romagnani[3], Mette Nørgaard[1], Kenneth J. Rothman[4,5] and Henrik Toft Sørensen[1]

[1]Aarhus University Hospital, Aarhus N, Denmark; [2]EpidStrategies, John Hopkins Campus, Rockville, MD; [3]Nephrology and Dialysis Unit, Meyer Children's University Hospital, Florence, Italy; [4]RTI Health Solutions, Research Triangle Park, NC; [5]Boston University, Boston, MA

Background: Acute kidney injury (AKI) is a common adverse drug reaction in cancer patients, but case-reports suggest that it may also be the first symptom of occult cancers and may worsen the prognosis of cancer.

Objectives: To examine the risk and prognosis of cancer following AKI.

Methods: We conducted this nationwide cohort-study in Denmark (population 5.6 million) using population-based medical databases. We identified all patients with hospital-diagnosed AKI between 1995 and 2017. We obtained data on any subsequent incident cancer (except non-melanoma skin cancer) and cancer stage. We quantified the 1-year and 1-5-year risk of cancer after AKI using the cumulative incidence method accounting for death as a competing risk. Standardized incidence ratios (SIRs) were computed as the observed number of cancers during the follow-up time divided by the expected number based on national cancer incidence rates by age, sex and calendar year. We computed five-year survival for patients diagnosed with solid and hematological cancer within one year after AKI using the Kaplan-Meier method and compared this with a cancer comparison cohort matched (1:5) on cancer site, age, sex, and year of cancer diagnosis. The 5-year hazard ratios (HR) of death with 95% confidence interval (95% CI) were computed using Cox regression analysis adjusted for age, sex, calendar year, Charlson Comorbidity Index Score, and cancer stage in solid cancers.

Results: We identified 29,977 patients with AKI. Among these, 1303 were diagnosed with cancer within the first year [1-year risk 4.4% (95% CI: 4.2—4.7) and SIR 4.6 (95% CI: 4.4—4.9)] and 827 were diagnosed with cancer 1-5 years after first AKI diagnosis [1-5 year risk 6.7% (95% CI: 6.3—7.2) and SIR 1.3 (95% CI: 1.2—1.4)]. The 1-year SIRs were highest for multiple myeloma, liver cancer, urological cancers, and cancer of the uterine cervix. The prevalence of distant metastases in solid cancer diagnosed within one year after AKI was similar in patients with and without a previous history of AKI (27% vs. 24%). The 5-year survival was 17% for patients with AKI and solid cancer and 39% in the corresponding comparison cohort (adjusted HR = 2.4, 95% CI: 2.1—2.8). The 5-year survival was 29% for patients with AKI and hematological cancer and 48% in the corresponding comparison cohort (adjusted HR = 2.8, 95% CI: 2.3—3.3).

Conclusions: Hospital-diagnosed AKI appeared to be a marker of occult cancer, but is also associated with an increased cancer rate beyond the first year, and signals a poor prognosis.

2594 | Methodologic considerations for evaluating adherence to oral oncologic therapy in a high mortality population

Danielle Chun[1], Blánaid Hicks[2], Sharon Peacock-Hinton[1], Hung-Jui Tan[3], Michele Jonsson-Funk[1], Alex Keil[1], Til Stürmer[1] and Jennifer Lund[1]

[1]Gillings School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Queen's University Belfast, Belfast, Ireland; [3]School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Continuous and on-time medication use is critical to for drug effectiveness and improving patient outcomes. However, key methodological decisions must be made when designing and analyzing studies of medication adherence and persistence in populations with a high risk of short-term mortality, such as the setting of metastatic cancer.

Objectives: To compare different measures of and approaches to quantifying adherence and persistence to oncologic therapy in a high mortality population using a motivating example of oral targeted therapy (TT) in patients diagnosed with metastatic renal cell carcinoma (mRCC).

Methods: Patients aged ≥66 years old with a primary diagnosis of mRCC who initiated TT within 4 months of their diagnosis were identified in the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked database from 2007-2015. We estimated 6-month adherence to oral TTs using an 80% threshold for proportion of days covered, including and excluding patients who died within 6 months. We then estimated the proportion of patients who were persistent (e.g., continuous TT users) at 6 months: (1) censoring patients at death and (2) treating death as a competing risk using nonparametric cumulative incidence functions. A gap of up to 30 days between TT fills was allowed.

Results: Among 507 mRCC patients initiating an oral TT (sunitinib:63%, pazopanib: 26%, sorafenib:10%), 32% died within 6 months. After excluding those who died, the proportion of adherent patients was substantially higher (38%) than when these patients were included but assigned zero days covered after death (26%). The proportion of patients who were persistent at 6 months was also substantially higher when censoring patients at death at 82% (95% confidence interval (CI): 78, 85%) compared with treating death as a competing risk at 50% (95% CI: 46, 54%).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Different approaches to the treatment of death result in substantially different estimates of oral oncologic adherence and persistence in high-mortality populations. This may have potential for bias when making comparisons in this setting. Because short-term mortality is so common in the metastatic cancer setting, studies of oncologic therapy adherence and persistence should explicitly report the proportion of patients who die over time and use appropriate methods to account for this competing risk.

2648 | The risk of late breast cancer recurrence in Denmark during 17 years of follow-up

Rikke Nørgaard Pedersen[1], Buket Öztürk[1], Lene Mellemkjær[2], Søren Friis[2], Bent Ejlertsen[3], Timothy L. Lash[4], Mette Nørgaard[1] and Deirdre Cronin-Fenton[1]

[1]Aarhus University, Aarhus, Denmark; [2]Danish Cancer Society Research Center, Copenhagen, Denmark; [3]Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [4]Rollins School of Public Health, Emory University, Atlanta, GA

Background: Breast cancer (BC) may recur many years after primary diagnosis. Therefore, it is necessary to extend the focus to identify patients at risk of late breast cancer recurrence (BCR) (>= 10 years after primary surgery).

Objectives: We investigated the incidence of late BCR and identified potential associations between clinico-pathological factors at baseline and late BCR.

Methods: Using the Danish Breast Cancer Group's (DBCG) database we identified all women with incident stage I-III operable BC diagnosed during 1987-2002, who were alive and without a recurrence or new primary cancer 10 years after diagnosis. We derived an algorithm to identify late BCR using Danish population-based registries. Follow-up began 10 years after primary surgery date and continued until late BCR, death, emigration, second cancer or 31/12/2013. Crude incidence rates (IRs) per 1,000 person-years (PY) and cumulative incidence proportions (CIPs) for late BCR were calculated by patient- and tumor characteristics at baseline. Cox regression models were used to calculate hazard ratios (HRs), accounting for competing risks. The HRs were adjusted for tumor- and patient characteristics.

Results: 18,117 women of 31,528 (57%) reached year 10 without BC recurrence, a contralateral breast cancer or other primary cancer, and were followed for a total of 106,602 PY with a median follow-up of 4.9 years (IQR; 2.4-8.7). Of these 10-year survivors, 1,763 developed late BCR corresponding to an IR of 16.5 (95% CI, 15.8-17.3) per 1,000 PY and a CIP of 15% maximum 27 years after primary diagnosis. The 10-15 years IR was 19.6 (95% CI, 18.6-20.7) per 1,000 PY, the 15-20 years IR was 11.8 (95% CI, 10.6-10.1) per 1,000 PY and the IR 20 years or more after primary surgery was 9.8 (95% CI, 8.0-12.0) per 1,000 PY. CIP was higher among patients with estrogen receptor $(ER)^+$ tumors, stage III disease and high nodal status. We found an adjusted HR of 3.0 (95% CI, 2.47-3.55) for patients with 4 or more positive lymph nodes versus patients with no lymph node involvement, an adjusted HR of 1.85 (95% CI, 1.59-2.15) for patients with stage III disease versus stage I disease and an adjusted HR of 0.57 (95% CI, 0.45-0.72) for patients with an ER^- tumor versus patients with an ER^+ tumor.

Conclusions: Conclusion: Our findings suggest that women with breast cancer can remain disease-free for at least ten years, but recurrences continue to occur from 10 to 27 years after primary diagnosis. Baseline tumor characteristics such as lymph node status, stage, and ER receptor status seems to be associated with late breast cancer recurrence.

2653 | Improving predictive ability of survival models: Comparison of multiple state of the art models

Hugo Loureiro[1,2], Tim Becker[1], Anna Bauer-Mehren[1], Narges Ahmidi[2] and Janick Weberpals[1]

[1]Roche Innovation Center Munich (RICM), Penzberg, Germany; [2]HelmholtzZentrum München, Neuherberg, Germany

Background: More complex statistical methods are being suggested to increase the predictive power of survival models when analyzing electronic health record (EHR)-derived datasets containing a massive number of patients and covariates.

Objectives: To determine if more complex survival analysis algorithms offer a gain in predictive ability over classical statistical methods when modelling oncological prognostic scores.

Methods: In this study, we used data from two datasets: Flatiron Health (FH) EHR-derived de-identified database for training and validation and OAK III clinical trial for validation. From FH we included 99,249 first-line treated patients with any cancer type. This cohort was split into a 90% training dataset and 10% validation dataset, respectively. The FH database comprises patient-level structured and unstructured data collected from more than 280 oncology clinics in the USA. With a new-user design, we defined overall survival as the time starting from the day of the first line treatment as index date until death due to any reason or censoring. A total of 26 covariates were measured in the 90 days before the index date. If there were multiple measurements available, the last observed value was chosen. To further validate our findings, we used data derived from the OAK (phase) III study. It is composed of 1187 patients with locally advanced or metastatic non-small-cell lung cancer (NSCLC) and compares the efficacy and safety of atezolizumab versus docetaxel. The models compared in this analysis included a conventional Cox model (CM), as well as Survival Forests (SF), Gradient Boosting (GB) and a neural network-based DeepSurv (DS) algorithm as the more complex models. The c-index was used as the performance metric to compare different models.

Results: Overall, the median survival across all patients was 581 days (95% CI 574-588). Within the FH database, the more complex models SF and GB (both c-index 0.722) and DS (c-index 0.720) seemed to perform marginally better than CM (c-index 0.695). However, when validating the models using the OAK III dataset, the superior

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

performance of SF, GB and DS disappeared and the predictive ability across all methods was comparable with c-indexes as high as 0.677 (SF), 0.6696 (GB), 0.676 (CM) and 0.675 (DS), respectively.

Conclusions: The more complex models are able to capture non-linearities and variable interactions that CM, due to its linear nature cannot. However, this did not lead to an increased predictive ability of the prognosis score across datasets.

3711 | Glucocorticoid use and breast cancer risk in a prospective cohort study of postmenopausal women

Manon Cairat[1], Marie Al Rahmoun[2], Marc Gunter[1], Gianluca Severi[2], Dossus Laure[1] and Agnes Fournier[2]

[1]International Agency for Research on Cancer, Lyon, France; [2]Centre de Recherche en Epidémiologie et Santé des Populations (CESP), équipe "Exposome, Hérédité, Cancer et Santé", Inserm UMR1018, Facultés de Médecine, Université Paris-Saclay, Université Paris-Sud, Gustave Roussy, Villejuif, France

Background: Trough their anti-inflammatory properties, glucocorticoids are hypothesized to prevent breast cancer. However, glucocorticoids are known to decrease glucose tolerance and to interact with the oestrogen pathways, two mechanisms involved in breast cancer development. Experimental data suggested that glucocorticoids could play a complex/dual role in breast cancer initiation and progression but epidemiological evidence are scare regarding the associations between glucocorticoid use and breast cancer risk.

Objectives: We investigated the association between glucocorticoid use and breast cancer incidence, overall and by subtypes, in the French E3N prospective cohort.

Methods: E3N includes 98,995 French women born between 1925 and 1950 and insured by a health insurance plan that covers mostly teachers. Information on lifestyle, anthropometric and reproductive factors, and medical history were collected biennially by self-questionnaires and matched with data from a drug reimbursement database pertaining to years 2004-2014. Women with at least two reimbursements in any 3-month period since 2004 were defined as ever exposed to glucocorticoids. Considering exposure as time-varying, multivariable Cox regression models were used to estimate hazard ratios (HRs) for the association of glucocorticoid use with breast cancer risk, overall and by breast cancer subtypes.

Results: In the current analysis, 62,390 postmenopausal women were followed between 2004 and 2014 (9 years on average, starting at a mean age of 63 years; 2,887 breast cancers). Of them, 28% had been exposed to glucocorticoids during follow-up. In multivariable models, there was no statistically significant association between ever use of glucocorticoids and breast cancer risk overall [HR= 0.96 (0.90 - 1.06)]. However, we found a statistically significant heterogeneity according to breast cancer subtypes suggesting an increased risk of *in situ* breast cancer and a decreased risk of invasive breast cancer [$HR_{in\ situ}$= 1.32 (1.00 - 1.75), $HR_{invasive}$=0.87 (0.77 - 0.98), $P_{heterogeneity}$=0.01] associated with glucocorticoid ever use.

Conclusions: Glucocorticoid use was associated with an increased *in situ* breast cancer risk and a decreased invasive breast cancer risk in this large, prospective cohort of postmenopausal women with 10 years of exposure information. Associations according glucocorticoid types, main breast cancer risk factors as well as potential confounding effect by other drugs/comorbidities will be explored and presented at the conference.

3727 | A US multicenter chart review study of patients with metastatic pancreatic ductal adenocarcinoma receiving liposomal irinotecan after gemcitabine-based therapy

Kenneth H. Yu[1], Andrew Hendifar[2], Olatunji Alese[3], Amber Draper[3], Maen Abdelrahim[4], Ethan Burns[4], Gazala Khan[5], Paul Cockrum[6], Rachel Bhak[7], Maral DerSarkissian[7], Catherine Nguyen[7], Mei S. Duh[7] and Nathan Bahary[8]

[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Emory Winship Cancer Institute, Atlanta, GA; [4]Houston Methodist Cancer Center, Houston, TX; [5]Henry Ford Cancer Institute, Detroit, MI; [6]Ipsen Biopharmaceuticals, Inc., Cambridge, MA; [7]Analysis Group, Boston, MA; [8]University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Real-world data allows healthcare decision-makers to assess and manage therapeutic and economic options for patients, including those who would and would not have met eligibility criteria for randomized control trials (RCT) and are instead managed under usual care.

Objectives: This retrospective multi-academic center chart review study describes real-world characteristics and outcomes of US patients receiving liposomal irinotecan for the management of metastatic pancreatic ductal adenocarcinoma (mPDAC).

Methods: Patients with mPDAC treated with liposomal irinotecan were eligible. Initiation of liposomal irinotecan defined index date; covariates assessed included clinical characteristics and treatment patterns; real-world overall survival (rwOS) was assessed via Kaplan-Meier methodology. The target enrollment is 300 patients. The study centers included were Memorial Sloan Kettering Cancer Center, Cedars-Sinai Medical Center, Emory Winship Cancer Institute, Houston Methodist Cancer Center, Henry Ford Cancer Institute, and University of Pittsburgh Medical Center.

Results: Data on 26 patients were available for initial analyses. Mean age was 68 years; 58% were female and 65% Caucasian. 54% of patients had stage IV disease at first diagnosis, and 17%, 65%, and 17% had index ECOG score of 0, 1, and 2, respectively. Common genetic mutations include KRAS (40%) and TP53 (40%). Prior to liposomal irinotecan, treatments received for metastatic disease include gemcitabine+nab-paclitaxel (77%) and fluorouracil (5-FU)/leucovorin (LV)+irinotecan+oxaliplatin (19%). Patients had received 0 (12%), 1 (23%), and ≥2 (65%) lines of therapy in the metastatic setting prior to liposomal irinotecan. Mean duration of liposomal irinotecan use was 3.0 months; liposomal irinotecan was mostly received with 5-FU

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(23%) or 5-FU/LV (69%). Median rwOS was 4.9 months (95% CI: 3.0, 6.3).

Conclusions: Real-world data of the first 26 patients in this study show patients treated with liposomal irinotecan are older, sicker, and have had more lines of therapy than previously reported in RCT data.

3918 | Declines in health related quality of life among older patients with hematologic malignancies

Ashwini Zolekar[1], Nadia A. Nabulsi[1], Alemseged A. Asfaw[1], Jifang Zhou[1], Karen Sweiss[1,2], Pritesh R. Patel[2,3], Brian C.-H. Chiu[4], Edith A. Nutescu[1] and Gregory S. Calip[1,2]

[1]University of Illinois at Chicago College of Pharmacy, Chicago, IL; [2]University of Illinois Cancer Center, Chicago, IL; [3]University of Illinois at Chicago, Chicago, IL; [4]University of Chicago, Chicago, IL

Background: Although advances in novel therapy and stem cell transplantation have increased survival in patients with hematologic malignancies (HM), less evidence exists on the subsequent impacts of HM on HRQOL.

Objectives: The aim of this study was to evaluate changes in HRQOL following diagnosis of HM in a cohort of older Medicare beneficiaries.

Methods: This was a retrospective study utilizing the Surveillance, Epidemiology and End Results Medicare Health Outcomes Survey Data Resource. We included patients ages ≥65 years diagnosed with first primary leukemia, lymphoma or multiple myeloma between 1998 and 2014 who completed at least one survey within two years pre- and post-diagnosis. HRQOL was measured using the Short Form Health Survey (SF-36) composite scores with a minimum clinically important difference of 2 points. We also measured self-reported general health, depressive symptoms, and the deficit-accumulation frailty index before and after HM diagnosis. Patients with HM were compared to up to four patients without cancer with exact matching on age, sex, race, marital status, smoking status, education, comorbid conditions, proxy response and calendar time of HM diagnosis. Comparisons of means were performed between groups using ANOVA with adjustment for survey type.

Results: Among 401 patients with HM, mean (SD) age of diagnosis was 75.98 (6.2) years and 26% were diagnosed with leukemia, 57% with lymphoma, and 17% with multiple myeloma. No significant differences in HRQOL, self-reported health, depressive symptoms, or frailty were observed between patients with HM and their non-cancer matches (n=1578) before diagnosis. Substantial declines in HRQOL were observed across all types of HM after cancer diagnosis. Mean decreases in SF-36 scores among patients with HM (physical component score [PCS] -7.1, 95% CI -8.8, -5.5; mental component score [MCS] -3.4, 95% CI -4.9, -1.8) were greater in magnitude compared to declines in matched non-cancer patients (PCS -1.6, 95% CI -2.4, -0.7; MCS -0.6, 95% CI -1.3, 0.1). During follow-up, patients with HM also had higher rates of low self-reported health (46% vs. 27%), depressive symptoms (34% vs. 25%) and frailty (32% vs. 25%).

Conclusions: Our study found decreases in HRQOL measures among older patients with HM that were more than three-fold higher than the minimum clinically important differences in the general population and twice that reported in older patients with common solid tumors. Prospective studies and clinical trials in patients with HM should include measures that assess whether life-prolonging, novel therapies are also effective in preserving HRQOL.

3993 | Risks of squamous cell carcinoma of the lip and cutaneous melanoma in older Australians using hydrochlorothiazide (HCTZ)

Benjamin Daniels[1], Sallie-Anne Pearson[1], Claire M. Vajdic[1], Anton Pottegard[2], Nicholas A. Buckley[3], Nicholas A. Buckley[3] and Helga Zoega[1]

[1]University of New South Wales, Sydney, Australia; [2]University of Southern Denmark, Denmark, Odense, Denmark; [3]University of Sydney, Sydney, Australia

Background: HCTZ is first-line treatment for hypertension and among the most commonly used medicines in Australia. Recent evidence suggests increased risks of skin cancer, in particular squamous cell carcinoma (SCC), in association with HCTZ use.

Objectives: To determine the risk of SCC of the lip and melanoma among people prescribed HCTZ in Australia.

Methods: We conducted a case-control study nested within a population of veterans residing in New South Wales from 2004 through 2015, using data from the Australian Department of Veteran's Affairs linked with cancer registrations, hospitalisation and prescription dispensings. Among veterans 65 years and older, we identified incident cases of SCC of the lip (lip cancer) and of cutaneous melanoma (malignant melanoma), each matched by sex and age with up to 20 controls through risk-set sampling. We ascertained HCTZ use from dispensing data and classified use according to ever/never use and cumulative use. We estimated odds ratios (ORs) associating HCTZ use with lip cancer and malignant melanoma using conditional logistic regression, adjusting for predefined confounders obtained from dispensing and hospitalisation data. To assess potential confounding by indication, we repeated the analysis for other antihypertensives including furosemide, ACE inhibitors, ATII antagonists, calcium channel blockers (CCBs), and indapamide.

Results: For lip cancer (45 cases; median age 79 years; 56% male) ever-use of HCTZ yielded an OR of 2.6 (95%CI: 1.4 - 5.0) and high HCTZ use (≥25,000mg) an OR of 4.7 (95%CI: 1.61 - 13.7). For malignant melanoma (659 cases; median age 81 years; 67% male) ever-use of HCTZ resulted in an OR of 1.2 (95%CI 1.0 - 1.5) and high HCTZ use in an OR of 1.2 (95%CI: 0.8 - 1.8). For melanoma subtypes, we observed elevated ORs for superficial spreading melanoma (OR: 1.6; 95%CI: 1.2 - 2.2) with ever-use and for lentigo melanoma (OR: 2.1; 95%CI: 1.0 - 4.5) with high use of HCTZ. We found no association with nodular melanoma. We did not observe associations between

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

either cancer type and the use of furosemide, ACE inhibitors, ATII antagonists, CCBs, or indapamide.

Conclusions: Our study provides further evidence that the photosensitising properties of HCTZ may promote SCC carcinogenesis, and possibly melanoma, in susceptible sun-exposed tissues. Our findings are the first from the Australian population—already at elevated risk of developing skin cancer—and add to the growing body of data supporting the need for skin cancer prevention advice and behaviours, and potentially heightened surveillance, for individuals prescribed this medication.

4067 | Mortality after late breast cancer recurrence in Denmark

Rikke Pedersen[1], Lene Mellemkjær[2], Søren Friis[2], Bent Ejlertsen[3], Mette Nørgaard[1] and Deirdre Cronin-Fenton[1]

[1]Aarhus University, Aarhus, Denmark; [2]Danish Cancer Society Research Center, Danish Cancer Society, Copenhagen, Denmark; [3]Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

Background: Data on mortality after late breast cancer recurrence (BCR) (≥10 years after primary diagnosis) is sparse. The few existing studies have focused on incidence and risk factors for late BCR while data on the outcome of late BCR is lacking.

Objectives: To investigate survival after late BCR focusing on potential prognostic factors, such as localization of late BCR and characteristics of the primary tumor.

Methods: From the Danish Breast Cancer Group database, we assembled a cohort of 31,528 women with incident operable stage I-III breast cancer (BC) diagnosed during 1987-2002. Among 18,117 women who were alive, without BCR or new primary cancer 10 years after diagnosis, 1,763 developed late BCR. We followed these patients from the date of late BCR to date of death (due to BC or other causes), emigration or December 31, 2018. We calculated the cumulative incidence proportions (CIPs) of BC death overall, by localization of the late BCR, and by characteristics of the primary tumor. We computed mortality rates (MRs) per 1000 person-years (PY) stratified by follow-up time. We used Cox regression to compute hazard ratios (HRs) and 95% confidence intervals (95%CI), adjusting for confounders and accounting for competing risks.

Results: The 1,763 patients generated 106,602 PY of follow-up. Median follow up was 5.6 years (IQR; 2.4-8.6). In total, 818 women died from BC and 303 died from other causes. The 2-year CIP of BC death was 17%, 5-year CIP 34%, 10-year CIP 47%, and 20-year CIP 55%. The CIP of dying from other causes was 25% 20 years after late BCR. The 20-year CIP of BC death was 79% in patients diagnosed with distant late BCR, 14% in patients diagnosed with locoregional late BCR, and 42% in patients with both locoregional and distant spread at diagnosis of late BCR. Patients with stage III disease and ≥4 involved lymph nodes at primary tumor diagnosis had higher CIPs of BC death after late BCR. The MR 5 years after late BCR was 91.0 (95%CI=90.6-113.3) per 1000 PY, 62.8 (95%CI=54.5-72.4) per 1000 PY from year 5-10, and 29.6 (95%CI=20.9-41.8) per 1000 PY from year 10-20. The HR for BC death was 6.1 (95%CI=4.7-8.0) per 1000 PY for patients with distant late BCR and 2.8 (95%CI=1.9-4.2) per 1000 PY for patients with both distant and locoregional spread at diagnosis of late BCR compared with those with locoregional late BCR. Tumor characteristics at primary BC diagnosis were not associated with BC mortality in patients with late BCR.

Conclusions: Mortality after late BCR is high especially among patients diagnosed with distant late BCR. The MR is highest in the first 5 years after late BCR, but BC deaths continue to occur during follow-up.

4102 | Adverse mental health outcomes in women with a history of breast cancer: A matched population-based cohort study in the United Kingdom (1988-2018)

Helena Carreira[1], Rachael Williams[2], Garth Funston[3], Susannah Stanway[4] and Krishnan Bhaskaran[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]Clinical Practice Research Datalink, London, United Kingdom; [3]Univeristy of Cambridge, Cambridge, United Kingdom; [4]The Royal Marsden NHS Foundation Trust, London, United Kingdom

Background: Treatments for breast cancer are highly effective, but carry the risk of several short- and long-term side effects that may negatively affect patients' mental health.

Objectives: To estimate the risk of anxiety and depression (primary outcomes), and seven secondary mental health-related outcomes, in breast cancer survivors compared to women with no prior cancer.

Methods: This was a matched population-based cohort study. The exposed cohort included all adult women diagnosed with an incident breast cancer between 1988 and 2018 in the Clinical Practice Research Datalink (CPRD) GOLD primary care database; women with history of other cancers were excluded. The unexposed cohort comprised a random selection of women with no cancer history, matched to exposed women on age and primary care practice. Median follow-up was 4.5 years in the exposed group and 5.2 years in the comparison group. The outcome measures were relative risks of the primary and secondary outcomes, calculated using Cox proportional hazards models, adjusting for confounders.

Results: 57,571 women diagnosed with breast cancer (mean age 62.3 ± 13.9 years) and 230,067 women with no previous cancer were included. Breast cancer survivorship was positively associated with the primary outcomes of anxiety (adjusted hazards ratio=1.33; 95%CI: 1.29-1.36), and depression (1.35; 1.32-1.38), and the secondary outcomes of fatigue (1.28; 1.25-1.31), pain (1.22; 1.20-1.24), sexual dysfunction (1.27; 1.17-1.38), sleep disorder (1.68; 1.63-1.73) and being prescribed opioid analgesics (1.86; 1.83-1.90), but there was no evidence of an association with cognitive dysfunction (1.00; 0.97-1.04) or fatal and non-fatal self-harm (1.15; 0.97-1.36). Hazard ratios for anxiety and depression reduced over time ($p < 0.001$) but raised risks persisted for two and four years, respectively, after cancer diagnosis. For the secondary outcomes, increased levels of pain and sleep disorder persisted for at least 10 years. Younger age was associated with

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

larger increases in the risks of depression, cognitive dysfunction, pain, opioid analgesic use and sleep disorders (p-interaction < 0.001 in each case).

Conclusions: Breast cancer survivorship is associated with raised risks of anxiety and depression, as well as other adverse mental health-related outcomes, persisting well into the survivorship period. Future research should investigate the role of direct toxicities of anti-cancer treatments versus other psychosocial impacts of cancer in driving these risks.

4165 | Epidemiology of HER2+ metastatic breast cancer in Germany and France in 2019

Kendra DeBusk[1], Naomi R.M. Schwartz[2], Susan Dennett[3], Nicolas Lindegger[4] and Sonia Pulgar[1]

[1]Seattle Genetics, Bothell, WA; [2]University of Washington, Seattle, WA; [3]Strategic Health Outcomes, Inc., Carmel, IN; [4]SeaGen International GmbH, Zug, Switzerland

Background: The real-world incidence of HER2+ metastatic breast cancer (MBC) in Europe is not well-established. Population-based registries in some countries capture incident *de novo* MBC, but these data may underestimate the incidence because they do not capture new cases of MBC that result from progression of early breast cancer (EBC) after neoadjuvant/adjuvant treatment. Accurate estimates of MBC incidence are important for researchers and policy makers who use these data for healthcare decision-making.

Objectives: To estimate the incidence of HER2+ MBC in Germany and France in 2019.

Methods: Patient flow models for 2019 were developed using data from a targeted literature review and the International Agency on Cancer GLOBOCAN database, which provides estimates of cancer in multiple countries, as well as the most robust data from the literature for each country. We extracted estimates of breast cancer incidence for Germany and France from GLOBOCAN. Estimates of *de novo* MBC incidence, frequency of HER2+ disease, and 5-year progression rates from EBC to MBC for these countries were obtained from population-based, observational studies published since 2010. Studies were assessed for quality based on inclusion/exclusion criteria, sample size/data source, time period, and methodology.

Results: Estimates from the patient flow models show that in Germany, an estimated 71,888 patients had incident breast cancer (GLOBOCAN); 4,601 (6.4%) had *de novo* MBC, of whom 828 (18.0%) were HER2+. Of patients with incident EBC (n=67,287), 8,142 (12.1%) were HER2+ and 1,083 patients (13.3%) progressed to HER2 + MBC. In total, an estimated 1,911 patients were newly diagnosed with or progressed to HER2+ metastatic disease in Germany in 2019. In France, 56,162 patients had incident breast cancer (GLOBOCAN); 3,201 (5.7%) had de novo MBC, of whom 650 (20.3%) were HER2+. Of patients with incident EBC (n=52,961), 8,474 (16.0%) were HER2+ and 1,059 progressed to HER2+ MBC (12.5%). In total, an estimated 1,709 patients were newly diagnosed with or progressed to HER2+ metastatic disease in France in 2019.

Conclusions: These estimates provide important insight into the burden of HER2+ MBC in Germany and France in 2019. The inclusion of incident HER2+ MBC that results from the progression of EBC in the models provides more robust estimates of HER2+ MBC incidence than are currently available for these countries. Future research to incorporate patient survival in the models could extend these estimates to HER2+ MBC prevalence.

4175 | Association of calcium channel blocker subtypes and prostate cancer related mortality

Kevin Yan[1,2], Kathy Li[1,2], Mahyar Etminan[1], HJ Gober[1,2] and Bruce Carleton[1,2]

[1]University of British Columbia, Vancouver, BC, Canada; [2]BC Children's Hospital Research Institute, Vancouver, BC, Canada

Background: In Canada, prostate cancer (PC) is the most common cancer diagnosis in men. There is limited evidence on CCB use and PC outcomes.

Objectives: In this epidemiologic study we examined different subclasses of calcium channel blockers (CCB) and their association with PC-related mortality.

Methods: An observational active-comparator study was conducted to examine the association between CCB subtypes and PC-related mortality. The data was obtained from the BC Cancer Agency Registry and all newly diagnosed stage 1 or stage 2 PC patients between 1996 to 2010 were included. Four groups of patients were compared: 1) non CCB users; 2) pure dihydropyridine (DHP) CCBs users (amlodipine, nifedipine); 3) pure diltiazem (DILT) users; and 4) pure verapamil (VERAP) users. Non-CCB users must have used an angiotensin converting enzyme inhibitor (ACEi). Individuals were followed from the index date and to either of the following, 1) mortality date, 2) time of switch between ACE-Is and CCBs, 3) last health service record date, 4) end of study follow up period (12/31/2010), whichever came first. We defined exposure to CCBs and ACEis as having received at least 2 prescriptions in six months prior to one year of the index date. Comorbid conditions were accounted for using the Charlson Comorbidity Index and covariates were adjusted using a multivariable cox regression. To control for PC latency and to prevent reverse causality bias, deaths within the first year of follow-up were excluded from the analysis. Fine and Gray's extension of Cox regression was used to model the multiple failure events data associated with different causes of mortality, to address competing risk bias.

Results: A total of 7,056 patients were included in the study: 1,467 in the DHP cohort; 794 in the DILT cohort; 251 in the VERAP cohort; and 4,544 in the non-CCB cohort. Patient ages were relatively equally distributed across all groups. The adjusted multivariable analysis favoured DILT demonstrating a significant decreased risk of experiencing PC-related mortality compared to non-CCB users (HR: 0.69, 95% CI: 0.54-0.89, p=0.0039). There was no association in both the DHP (HR: 1.08, 95% CI: 0.90-1.29, p=0.4237) and VERAP (HR: 0.85, 95% CI: 0.57-1.23, p=0.3633) groups compared to non-CCB users.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: This preliminary population study shows an association between DILT and PC-related mortality. Limitations include the absence of assessing duration of CCB use prior to and post-diagnosis of PC. However, we are in the process of replicating our findings using PC data from a different cancer institute and will include duration of CCB use in our future analysis.

4183 | Comparative risks of cardiotoxicity following initiation of checkpoint inhibitors, BRAF/MEK inhibitors, and interferon alpha in patients with metastatic melanoma

Benjamin Bates, Poonam Gandhi and Soko Setoguchi
Rutgers, New Brunswick, NJ

Background: Checkpoint inhibitors (CPi) activate anti-tumor T cells and have demonstrated improvement in overall survival for patients with metastatic melanoma. Severe cardiotoxicity has been reported, but little is known concerning comparative risks of cardiotoxicity among available treatments for metastatic melanoma.

Objectives: To compare risks of cardiac events in melanoma patients who initiated CPi, BRAF/MEK inhibitors (BMi), or interferon alpha-2b (IFN).

Methods: We identified patients with ≥1 diagnosis of melanoma followed by an initiation of a therapy used for metastatic melanoma, i.e., CPi, BMi, and IFN in MarketScan commercial and Medicare databases (2011-2017). The primary outcome was a composite of all cardiac events including myocardial infarction, heart failure and other cardiovascular hospitalizations. The secondary outcome was a composite of immune-related cardiac events, including myocarditis/pericarditis, takotsubo cardiomyopathy, ventricular arrhythmia, and heart block with pacemaker placement. We described patient characteristics and calculated incidence rates (IRs) of outcomes and their 95% confidence intervals (CIs). We used Cox regression to estimate hazard ratios (HRs) and their 95% CIs after adjusting for potential confounding using propensity score (PS).

Results: We identified 15,693 melanoma patients initiating CPi (65%), BMi (2%), or IFN (33%). CPi users on average were slightly older (age 62) compared to IFN (age 60) and BMi (age 54); IFN had higher proportion of males (68%) than CPi (58%) or BMi (54%). During 6,654 person-years on therapy, we observed an IR of 288, 136, and 447 per 1000 person-years in CPi, BMi, and IFN, respectfully. For all cardiac events comparing CPi to BMi, the risks were similar (adjusted HR 1.1 [95% CI: 0.7-1.8]). However, CPi users had significantly lower risk compared to IFN users (adjusted HR 0.6 [95% CI: 0.5-0.7]). Secondary analysis comparing the risk of immune related cardiotoxicity in CPi vs IFN demonstrated a significant reduction in the risk (adjusted HR 0.3 [95% CI: 0.3-0.4]).

Conclusions: In real-world melanoma patients, we found CPi did not increase the risk of cardiac events compared to BMi or IFN. IFN, in fact, demonstrated higher risk of overall cardiac events and immune-related cardiac events compared to CPi, consistent with FDA boxed warning for IFN causing life-threatening autoimmune diseases. More studies with larger sample size and better identification of melanoma characteristics is needed to better quantify the comparative risk of CPi cardiotoxicity.

4199 | Thiamine deficiency as a misdiagnosed and unrecognized cause of delirium in referred patients with cancer

Hideki Onishi[1], Izumi Sato[2] and Mayumi Ishida[1]
[1]*Saitama Medical University International Medical Center, Hidaka, Japan;* [2]*Department of Pharmacoepidemiology, Graduate School of Medicine and Public Health, Kyoto University, Kyoto, Japan*

Background: Thiamine deficiency (TD) may increase the risk of delirium among patients with cancer. However, the TD is unrecognized or overlooked because of symptomless or unspecific symptoms, and that may lead to severe brain damage. Previous studies did not revile the prevalence of TD among cancer patients with delirium.

Objectives: To investigate the percentage of TD and the patients' background characteristics among patients with cancer who were referred to the department of psycho-oncology for developing delirium from oncologists in the cancer center of the university hospital.

Methods: We conducted a cross-sectional study to describe the prevalence of TD and the patients' characteristics using electrical medical records in the cancer center on University hospital, including patients with cancer aged 18 years or older who were referred for the incidence of delirium to the psycho-oncologist from October 2014 to March 2018. We collected patients' backgrounds (e.g., age, gender), and cancer-related data (primary site of cancer, performance status, treatment within two months before the blood sampling), and results of blood test (vitamin B1, albumin, and lactate dehydrogenase). We calculated descriptive statistics to summarize them, the prevalence of TD, and the percentage of undiagnosed TD. Then we performed multivariable logistic regression analysis to investigate the association between thiamin deficiency and socio-demographics, cancer-related states, and blood tests.

Results: We identified 71 patients diagnosed with delirium by psycho-oncologist (mean age 69.6 years old; 66% male). TD was found in 45% of the patients. Of these patients with TD, 60% were misdiagnosed and unrecognized by the oncologists at the time of consultation. Patients with TD were more likely to be diagnosed with gastroenterological cancer, had lower albumin levels, lower BMI, and received chemotherapy. We found the association between chemotherapy and TD (adjusted OR, 1.98; 95%CI [1.04-3.77]).

Conclusions: We found 45% of TD in patients with cancer developing delirium who were referred to psycho-oncologist in the cancer center of the University hospital. Although TD was not rare, more than half of these patients were unrecognized by the TD by oncologists at a consultation. Oncologists should be more careful about detecting TD when patients with cancer develop delirium.

4205 | Risk of malignancy in rheumatoid arthritis patient and association with biologic DMARDs using national health insurance service claim database

Sang Oh Kang, Kyung Hyun Min, Harim Yeon and Kyungeun Lee
Chung-Buk National University College of Pharmacy, Cheong-ju, Republic of Korea

Background: Since the development of biologic disease-modifying anti-rheumatic drugs (bDMARDs), treatment outcome for rheumatoid arthritis (RA) has been improved in the aspect of effectiveness. But, in regard to safety, concerns about malignancy risk has been raised.
Objectives: The aim of this study was to investigate the risk of malignancy in RA patients especially in bDMARDs users.
Methods: A retrospective cohort study was conducted using the customized RA cohort database from Korean National Health Insurance database. From 2002 to 2017, A total of 928,200 patients were included in the database and 232,050 were identified as RA patients. In a disease association analysis, RA patients treated with conventional synthetic DMARDs (csDMARD) were enrolled as the case group. Patients who had never been diagnosed RA nor prescribed DMARDs were classified as the control group. We examined the association of RA with malignancy by comparing the incidence of malignancy in both groups. In an analysis between malignancy and bDMARDs, bDMARDs users were defined by patients who were prescribed more than three times within 6 months from the first prescription and non-bDMARDs group was patients who had never been prescribed bDMARDs. The outcome of this study was malignancy occurrence during drug exposure or within 90 days after last drug prescription. We compared the malignancy incidence using incidence rate ratio (IRRs) after adjustment for age, gender and Charlson comorbidities index.
Results: After exclusion, 900,283 patients were included in this study. In a disease association analysis, 227,764 were in RA group and 672,519 were in control group. In RA group, during 1,732,896 person-years (PY) of follow up, 41,486 malignancies were detected (2394/100,000 PY). In non-RA group, IR was 114,630/4,527,648 PY (2532/100,000 PY). IRR between RA group and non-RA group was 0.946 (95% CI 0.943-0.948, $p<0.05$). In the analysis between malignancy and bDMARDs, there were 10,099 patients using bDMARDs and 151,570 patients without bDMARDs in non-bDMARDs group (who were prescribed csDMARDs more than three times). IR was 647/2132 PY (1657/100,000 PY) for bDMARD user and 16,393/84068 PY (2250/100,000 PY) for bDMARD non-user, resulting IRR of 0.736 between bDMARD users and non-bDMARD users (95% CI 0.734-0.739, $p<0.05$).
Conclusions: The incidence of malignancies was lower in RA group when compared with non-RA patients. The overall risk of malignancies was decreased in bDMARD user as compared with non-bDMARD user.

4213 | Disease characteristics, treatment and clinical outcomes of patients with B-cell non-Hodgkin lymphoma: A retrospective study in Taiwan

Sung-Nan Pei[1], Hong Qiu[2], Lee Anne Rothwell[3] and Yanfang Liu[4]
[1]Division of Hematology/Oncology, Chia-Yi Chang Gung Memorial Hospital, Division of Hema-Oncology, Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital, and Chang Gung University College Medicine, Chia-Yi, Taiwan; [2]Global Epidemiology, Janssen Research & Development, Titusville, NJ; [3]Janssen Medical Affairs, Macquarie Park, Australia; [4]Global Epidemiology, Janssen Research & Development, Singapore, Singapore

Background: Despite improved survival associated with the use of rituximab in standard chemotherapy regimens for B-cell Non-Hodgkin lymphoma (BNHL), survival remains poor. Understanding the current disease journey will facilitate evaluations of effectiveness of new therapies that may enter the market in coming years.
Objectives: To evaluate the clinical characteristics, treatment, outcomes and survival among patients with BNHL (subtypes DLCBL, FL, CLL/SLL, MZL, MCL, WM).
Methods: We conducted a retrospective cohort study using electronic medical records from Kaohsiung Chang Gung Memorial Hospital, a regional tertiary hospital in southern Taiwan, from 01 January 2008 to 31 December 2017. All adult patients with a new diagnosis of BNHL (ICD-O 9680/3, 9823/3, 9673/3, 9690/3, 9699/3, 9761/3) from January 01, 2008 until December 31, 2013 were included and followed until 31 December 2017. Patients with a previous malignancy were excluded. Deaths were captured from the hospital database and correlated with the National Death Registry. Event-free survival (EFS) and overall survival (OS) were calculated using Kaplan-Meier methods.
Results: 441 patients were newly diagnosed with BNHL between 2008-2013; 54.6% were diagnosed with DLBCL, 15.2% with FL, 13.8% with MZL, 10.7% with CLL/SLL, 3.4% with WM, and 2.3% with MCL. More than 50% of patients were diagnosed with Stage III or IV disease, except for MZL (16.4%). At diagnosis, 19.5% of patients with DLBCL were positive for hepatitis B surface antigen and 15.8% were positive for hepatitis C virus. Active treatment was administered to 397 patients (81.7%). Complete and partial response rates after first line treatment were 57.6% and 18.3% for DLBCL, 54.0% and 33.3% for FL, 57.9% and 28.1% for MZL, and 30.0% and 30.0% for MCL. Partial response rate was 42.9% for WM. The relapse rate after first line treatment was highest in MCL (20%) and lowest in MZL (8.8%). 5-year OS was 86.7% for MZL, 76.2% for FL, 71.0% for CLL/SLL, 58.3% for WM, 52.7% for DLBCL, and 20.0% for MCL. OS was significantly reduced in patients with an early disease flare (relapse <6 months after commencing chemotherapy) compared with disease flares after 6 months (median OS 0.75 yrs versus 4.47 yrs, $p=0.037$). 2-year EFS was 49.1% for DLBCL, 63% for FL, 62% for MZL, 10% for MCL, 0% for WM.
Conclusions: More than half of BNHL patients presenting to this tertiary hospital in Taiwan had advanced disease at diagnosis. More than 75% with DLCBL, FL or MZL responded to conventional chemotherapy but response rates in WM and MCL were low. New treatments are needed to improve the outcome of BNHL.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4223 | Novel use of the England National Cancer Registry to describe treatment patterns and disease outcomes in patients with advanced or metastatic cancer

Francois-Xavier Lamy[1], Craig Knott[2,3], James Harnett[4], Amerah Armin[5], Leo Russo[6], Emmanuelle Boutmy[1] and Patrice Verpillat[1]
[1]*Merck KGaA, Darmstadt, Germany;* [2]*HealthDataInsight CIC, Cambridge, United Kingdom;* [3]*Public Health England, Cambridge, United Kingdom;* [4]*Pfizer Inc., New York, NY;* [5]*Merck Serono Ltd, Feltham, United Kingdom;* [6]*Pfizer Inc., Collegeville, PA*

Background: The recent approvals of immuno-oncology (IO) treatments for several types of cancer is expected to substantially impact the standard of care and clinical outcomes. Real-world data (RWD) on the treatments and outcomes for patients with advanced or metastatic cancer would provide relevant supplementary evidence to clinical trial results.
Objectives: To set up and describe 4 open-ended cohorts of patients diagnosed in England with advanced or metastatic cancer where IOs were recently approved: Merkel cell carcinoma (MCC), non-small cell lung cancer (NSCLC), renal cell carcinoma (RCC) and urothelial carcinoma (UC). We report here the first results for these cohorts.
Methods: The cohorts were identified using the National Cancer Registration and Analysis Service (NCRAS) in England. In addition, patient-level linkage was used to extract comprehensive national data on the disease (national cancer registry), inpatient, outpatient and emergency admissions and diagnoses (Hospital Episode Statistics), anticancer radiotherapy (National Radiotherapy Dataset), systemic anticancer treatments (Systemic AntiCancer Therapy database), and mortality (Office for National Statistics). Adult patients were included following diagnosis date (index date) of stage III or IV MCC, NSCLC, RCC or UC between January 2013 and June 2017 for the first data cut-off. Patients identified through death certificates only, or those receiving systemic therapy via the cancer drug fund were not included. The follow-up period ran from index date to the earliest of death, loss to follow-up or end of study period (March 2018). Overall survival (OS) was estimated by Kaplan-Meier from index date to death, censoring at loss to follow-up or end of study period.
Results: A total of 392 MCC (of which 32.7% were stage IV at diagnosis), 67,148 NSCLC (68.4% stage IV), 14,629 RCC (57.5% stage IV) and 10,510 UC (68.1% stage IV) patients were included in each corresponding cohort. Systemic treatments were reported for 18.4% of MCC, 42.1% of NSCLC, 24.3% of RCC and 26.6% of UC patients. Use of IO was reported in all cohorts but limited (<10%). Median OS from diagnosis ranged from 6.0 months in the NSCLC cohort to 21.6 months in the RCC cohort.
Conclusions: Robust RWD relying on secondary use of data can provide relevant supplementary information to clinical trials on the rapidly evolving anticancer treatment landscape and disease outcomes following the advent of IO therapy. Furthermore, the open-ended nature of these cohorts will offer the opportunity to describe these changes over time at future data releases.

4253 | Parity, use of statins and breast cancer risk in a Danish population-based cohort

Agnès Fournier[1], Aurélie Mailhac[2], Bianka Darvalics[2], Henrik T. Sørensen[2], Marc J. Gunter[3] and Deirdre Cronin-Fenton[2]
[1]*Université Paris-Saclay, UVSQ, Inserm, Paris, France;* [2]*Aarhus University, Aarhus N, Denmark;* [3]*International Agency for Research on Cancer, Lyon, France*

Background: While statin use is associated with better disease-free survival after breast cancer (BC) diagnosis, these widely used lipid-lowering drugs have shown inconsistent associations with primary BC incidence. Previously, in a French cohort study of postmenopausal women aged an average of 63 years old at baseline, statin use was found to be associated with decreased BC risk (-20%) only among women with at least 3 full-term pregnancies. Whether such an interaction is observable in other cohorts is not known.
Objectives: To assess the association between statin use and BC incidence according to parity using data from a Danish nationwide cohort.
Methods: Our source population was all female residents of Denmark born 1955-1960. Information on the number of full-term pregnancies was ascertained from the Danish Medical Birth Register established in 1973 and was hence considered complete for women born from 1955. In our analysis, we included women aged at least 45 years old in 2000-2005, our enrollment period, i.e. born until 1960. They were followed for invasive BC incidence from age 45 through December 2014. Exposure was defined as at least one statin prescription identified since 1995 from the Danish National Prescription Registry. Deaths and cancers were ascertained using the Danish Civil Registration System and the Cancer Registry. We fitted Cox regression models to compute hazard ratios (HR) between statin exposure, treated as a time-varying lagged variable, and incident invasive BC risk. We adjusted our models for age (time scale), Charlson comorbidity index and prescriptions for hormone replacement therapy, oral contraceptives, antihypertensive drugs, hypolipidemic drugs other than statins, antidiabetics, low-dose aspirin and bisphosphonates.
Results: A total of 198,539 women without cancer before the age of 45 years were followed for a median of 11.8 years, during which 5421 invasive BCs occurred. At the end of follow-up, 17% had been ever exposed to statins. Statin use was not associated with BC incidence, neither among all women combined (HR = 0.94, 95% CI = 0.84-1.06) nor by any parity strata: the HRs were 0.78 (0.58-1.06), 1.08 (0.84-1.39), 0.91 (0.76-1.10), and 1.01 (0.78-1.32) among women with 0, 1, 2, and 3+ full-term pregnancies, respectively (p homogeneity = 0.59).
Conclusions: In this cohort of women followed from age 45 up until 60 years old, there was little evidence of an association between exposure to statins and invasive BC risk, neither overall nor by parity strata. Whether associations would differ in older women should be explored in future studies.

4298 | Evaluation of electronic health record (EHR) data of patients with acute myeloid leukaemia (AML) for real-world data analyses

Charlotta Früchtenicht[1], Evelyn M. Flahavan[2], Tao Xu[1], Tarec Christoffer El-Galaly[1], Jessica Davies[2], Craig Gower-Page[2] and Anne-Marie Meyer[1,3]

[1]F. Hoffmann-La Roche Ltd., Basel, Switzerland; [2]Roche Products Limited, Welwyn Garden City, United Kingdom; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Care pathways in aggressive diseases like AML are complex and occur in multiple clinical settings which are not typically captured by a single EHR. Understanding this complexity is critical to capturing treatments and outcomes in real world patients and identifying sources of bias to address in the study design.

Objectives: To assess the completeness of patient data captured from AML patients in oncology clinic EHRs and quantify the potential biases that impact study design.

Methods: De-identified patient-level data was obtained from Flatiron Health's (FIH) database (December 2019 release), including patients diagnosed with AML (excluding acute promyelocytic leukemia) between 01/2014 and 11/2019 with at least two distinct clinic visits on or after January 1, 2014. Patient information was aggregated from either structured data collected within the FIH network EHR or abstracted from unstructured information in the EHR by an expert reviewer. We combined structured and abstracted data to describe treatment and outcomes observed within and outside of the clinic network. Gaps in care were identified by absence of activity data from any source.

Results: The source cohort consisted of 815 patients of which 809 (99.2%) had structured clinical activity after abstracted diagnosis (Dx) date. Gaps in patient care are rare in AML, however, 136 patients (17%) showed at least one activity gap of more than three months in the first year post-Dx.

Structured Tx data was available post-Dx for 590 patients, however Tx for an additional 145 patients was captured from abstracted data (oral or intravenous (IV)), increasing the treated cohort to n=735. Of these, 700 (95%) could be assigned a first line (1L) Tx regimen. The vast majority (n=617, 88%) received antineoplastic Tx within 31 days after AML Dx.

One-third of the patients did not have structured data concurrently with their abstracted Dx date and were likely diagnosed outside the network. Furthermore, among the 1L treated patients, 212 (31%) of patients had evidence of 1L Tx likely outside the network based on evidence of Tx abstracted from unstructured data and no structured drug administrations during 1L in the network.

Conclusions: This analysis demonstrates the complexity of capturing Tx and outcome information in a disease where care may occur at multiple sites of care. Users must be knowledgeable about treatment pathways and vigilant about potential biases from missing data. Though, careful curation of EHR data shows that it is possible to recover substantial exposure information through the abstraction of data captured outside the structured EMR.

4397 | Incidence, prevalence, and survival in patients with metastatic non-small cell lung cancer in the United States (US)

Engels Chou, Alyssa B. Klein, Ion Cotarla and Brian Seal

AstraZeneca, Gaithersburg, MD

Background: Non-small cell lung cancer (NSCLC) represents approximately 85% of all lung cancers (LC). At the time of diagnosis, 70% of NSCLC patients already have locally advanced or metastatic disease not amenable to surgical resection. Furthermore, a significant percentage (30-55%) of early stage NSCLC patients who have undergone surgery subsequently develop distant metastases and die as a result of their lung cancer.

Objectives: To calculate the most recent epidemiology estimates of metastatic NSCLC (mNSCLC) in the US.

Methods: Patients diagnosed with NSCLC were identified from National Cancer Institute (NCI)'s Surveillance, Epidemiology, and End Results (SEER) and Centers for Disease Control and Prevention (CDC)'s National Program of Cancer Registries (NPCR) merged databases, as well as SEER-18 (data cut up to Dec 2016, staging available up to 2015). NPCR-SEER was used to calculate national age-adjusted incidence of NSCLC, while SEER18 was used to calculate age-adjusted incidence and prevalence, as well as survival by age group.

Results: In NPCR-SEER, NSCLC incident cases (N=161,273) accounted for 83.4% of all LC in 2016, and the incidence rate decreased from 45 per 100,000 in 2012 to 41.4 per 100,000 in 2016; Of these NSCLC patients, 68.2% were aged ≥65 years with a 16-fold incidence rate higher than that in <65 years (232.2 per 100,000 vs. 13.8 per 100,000). In SEER18, similar decreasing incidence rate of NSCLC was observed: 41.7 per 100,00 in 2012 decreased to 38 per 100,000 in 2016. In the most recent 5-year data, NSCLC incident cases accounted for 84.6% of all LC, and 49.2-51.9% of these cases were metastatic before adjusting for age. The incidence of mNSCLC in 2015 was 17.1 per 100,000, accounting for 37.2% of LC, or 44.3% of NSCLC after adjusting for age. The prevalence of NSCLC was 104.7 per 100,000 when extrapolated to the national level (prevalence was 500.4 per 100,000 for ages ≥65 years and 34.6 per 100,000 for <65 years). Of mNSCLC patients, 65.4% were aged ≥65 years with 16.3% being squamous, 68.8% adenocarcinoma, and 6.8% with non-small cell carcinoma; in patients <65 years, 21.4% were squamous, 64.5% adenocarcinoma, and 7.7% with non-small cell carcinoma. Survival for mNSCLC was low: 1-, 2-, 3-, 4-, and 5-year survival were 30%, 15.1%, 9.2%, 6.4%, and 4.8%, respectively. The 5-year survival was only 4% for patients ≥65 years (6.1% for <65 years), and 3.8% for males (6% for females).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Almost half of NSCLC incident cases were metastatic. About half of the prevalent mNSCLC patients were progressed from earlier stages. The 5-year survival rate was lower than 5% for mNSCLC patients.

4419 | KADor: A French retrospective study describing the therapeutic management of patients who received Herceptin® based neoadjuvant treatment for HER2+ early breast cancer (eBC)

Paul Cottu[1], David Perol[2], Olivier Tredan[2], Alain Livartowski[1], Melina Gilberg[3], Rim Ghorbal[3], Julien Dupin[3] and Cathy Maillard[4]
[1]*Institut Curie, Paris, France;* [2]*Centre Leon Berard, Lyon, France;* [3]*Roche SAS, Boulogne-Billancourt, France;* [4]*IQVIA, Paris la Defense, France*

Background: The results from the KATHERINE trial showed an improvement in invasive Disease-Free Survival (iDFS) associated with Kadcyla® administered as adjuvant therapy compared to Herceptin® in patients with HER2+ eBC who had residual invasive disease in the breast or axillary lymph nodes (incomplete pathological response, non-pCR) following conventional neoadjuvant therapy. These results led to the development of the observational study KADor to obtain French data on these patients' characteristics and therapeutic management.
Objectives: The main objective of this study was to describe the therapeutic management, between 2014 and 2018, of patients with HER2 + eBC who initiated neoadjuvant therapy in 2014. The estimation of the proportion of non-pCR patients and the iDFS were assessed as secondary objectives.
Methods: This was an observational, retrospective and multicenter study involving French HER2+ eBC patients who had initiated a Herceptin® based neoadjuvant treatment during 2014 followed by a surgery. A registry based medical records was first set up to capture the entire flow of patients managed in participating sites, then a follow-up cohort including patients treated with a Herceptin® based adjuvant therapy was created. A weighting was applied to control sites representativeness at the national level.
Results: Of the 460 French hospital sites (public/private) contacted, 57 participated in the study. The populations in the registry and the cohort were 306 and 301 patients respectively. The mean age of the patients included in the cohort was 52 years (±12.6). According to T (tumor size) and N (lymph nodes) staging of the primary tumor at diagnosis, the majority of patients were T2N0 (22.9%), T2N1 (22.2%) and T3N1 (13.3%). Nearly 60% of patients presented hormone receptors. More than half (57.1%) of the patients were non-pCR. The mean number of Herceptin® cycles administered was 13.2 (95% CI: 12.8- 13.6). Hormone therapy was administered to 47.5% of patients (95% CI: 41.9% - 53.1%). At 36 months, the iDFS rate was 84.1% (95% CI: 79.1% - 87.9%) for the entire cohort and 88.1% (95% CI: 80.7% - 92.8%) and 81.0% (95% CI: 73.8% - 86.4%) in pCR and non-pCR patients respectively.
Conclusions: The KADor study described the therapeutic management of HER2+ eBC patients who had initiated a Herceptin® based neoadjuvant treatment in France followed by a surgery and a Herceptin® based adjuvant therapy in real clinical setting. These findings indicate that routine practice aligns with the recommendations for therapeutic management.

4433 | Treatment patterns and clinical outcomes of patients with metastatic non-small cell lung cancer receiving immune checkpoint inhibitor monotherapy in the first-line setting in community-based practices in the United States

Evie Merinopoulou[1], Beth Nordstrom[2], Samuel Huse[2], Nataliya Trunova[3], Christianah Kolajo[3], Engels Chou[3] and Alyssa B. Klein[3]
[1]*Evidera, London, United Kingdom;* [2]*Evidera, Waltham, MA;* [3]*AstraZeneca Oncology Unit, Gaithersburg, MD*

Background: Until recently, platinum-based combination chemotherapy was the standard of care for first line (1L) therapy in NSCLC with little improvement on patient prognosis, especially at later stages. Despite the emergence of novel therapies marking a rapidly shifting treatment paradigm in mNSCLC, little is known on treatment patterns and clinical outcomes in the real-world setting.
Objectives: To describe patient characteristics and treatment patterns after initiating IO monotherapy in the mNSCLC setting, and to assess survival and progression outcomes.
Methods: Patients in the Flatiron Health Oncology electronic medical record database with a mNSCLC diagnosis, who had 1L IO monotherapy between 1 October 2016 - 31 May 2018 were identified. Patients were ≥18 years old, had no evidence of mixed small-cell histology, epidermal growth factor receptor (EGFR) or anaplastic lymphoma kinase (ALK) mutations prior to or at the start of 1L (index date). Clinical outcomes included overall survival (OS) and progression-free survival (PFS) from index and start of second line (2L), and second PFS (PFS-2), defined as the time from index to disease progression during 2L. Treatment patterns and clinical outcomes were described by line of therapy using descriptive statistics and Kaplan-Meier methods.
Results: A total of 1,851 patients who were diagnosed with mNSCLC during the study period initiated 1L IO monotherapy. Mean (standard deviation) age at index date was 70.7 (9.7) years, 54.8% were male, and 49.9% had Eastern Cooperative Oncology Group status 0-1 (missing: 32.9%). The most common 1L IO monotherapies were pembrolizumab (62.0%) and nivolumab (33.5%). Of the 508 patients who initiated 2L, 256 (50.4%) received chemotherapy alone, and 82 (16.1%) received anti- vascular endothelial growth factor (VEGF) regimens in combination with chemotherapy. Out of 160 patients initiating 3L, 78 (48.8%), received chemotherapy alone and 30 patients (18.8%) received IO monotherapy. Median OS and PFS from 1L were 12.2 months (95% confidence interval:11.4-13.5), and 9.2 months (8.5-10.2), and PFS-2 was 17.5 months (15.9-19.7). Starting from 2L, median OS and PFS were 9.7 months (8.3-11.3) and 7.0 months (6.3-7.9).
Conclusions: This real-world study found median survival of patients starting on IO monotherapy to be just over 1 year. Despite the introduction of new innovative therapies, clinical outcomes in mNSCLC

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

remain suboptimal, indicating a need for further improvements in treatment options.

4441 | Treatment patterns and clinical outcomes of patients with metastatic non-small cell lung cancer receiving immune checkpoint inhibitors in combination with chemotherapy in the first-line setting in community-based practices in the United States

Evie Merinopoulou[1], Beth Nordstrom[2], Samuel Huse[2], Nataliya Trunova[3], Christianah Kolajo[3], Engels Chou[3] and Alyssa B. Klein[3]
[1]*Evidera, London, United Kingdom;* [2]*Evidera, Waltham, MA;* [3]*AstraZeneca Oncology Unit, Gaithersburg, MD*

Background: For patients with mNSCLC, clinical trials have demonstrated that IO therapies plus chemotherapy provide considerable survival benefit compared to chemotherapy alone, however, current information from the real-world setting is limited.
Objectives: To assess patient characteristics, treatment patterns, survival and progression outcomes in patients with mNSCLC initiating IO in combination with chemotherapy (IO+chemo) in the United States.
Methods: Patients ≥18 years old with a mNSCLC diagnosis in the Flatiron Health Oncology electronic medical record database, who initiated first line (1L) IO (pembrolizumab, nivolumab, or atezolizumab) plus chemotherapy between 1 October 2016 - 31 May 2018, were included. Patients with evidence of mixed small-cell histology, epidermal growth factor receptor (EGFR) or anaplastic lymphoma kinase (ALK) mutations prior to or at the start of 1L (index date) were excluded. Kaplan-Meier methods estimated overall survival (OS) and progression-free survival (PFS) from index and start of second line (2L), and second PFS (PFS-2), from index to disease progression during 2L. Treatment patterns and clinical outcomes were described by line of therapy.
Results: A total of 700 patients diagnosed with mNSCLC during the study period initiated 1L IO+chemo and qualified for the cohort. Mean (standard deviation) age at index date was 66.9 (9.8) years, 56.9% were male, and 60.6% had Eastern Cooperative Oncology Group status 0-1 (missing: 28.9%). At 1L, 686 (98.0%) of patients received IO plus platinum-based chemotherapy (cisplatin, carboplatin), and 14 (2.0%) received IO plus other chemotherapy regimens. The most common treatments in 2L were chemotherapy only (77 [38.9%]), anti-vascular endothelial growth factor (VEGF) regimens plus chemotherapy (60 [30.3%]) and IO combinations (23 [11.6%]). Of the 63 patients who started on third line, 35 (55.6%) had chemotherapy, and 20 (31.7%) had anti-VEGF plus chemotherapy. Median OS and PFS from 1L were 12.5 months (95% confidence interval:10.2-14.4), and 8.6 months (7.5-9.7), and PFS-2 was 14.8 months (12.0-18.3). Starting from 2L, median OS and PFS were 8.2 months (6.8-9.6) and 4.9 months (4.1-6.5), respectively.
Conclusions: Despite the increasing use of innovative therapies in combination chemotherapy for the treatment of mNSCLC, survival and progression data from the real-world setting reveal a continued unmet need for improved therapies.

4503 | Use of proton pump inhibitors and histamine-2 receptor antagonists and risk of gastric cancer in two population-based studies

Peipei Liu[1], Úna McMenamin[1], Brian Johnston[2], Peter Murchie[3], Lisa Iversen[3], Amanda Lee[3], Pauline Vissers[4] and Christopher Cardwell[1]
[1]*Queen's University Belfast, Belfast, United Kingdom;* [2]*Belfast Health and Social Care Trust, Belfast, United Kingdom;* [3]*University of Aberdeen, Aberdeen, United Kingdom;* [4]*Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands*

Background: Previous studies have shown increased gastric cancer risk in users of proton pump inhibitors (PPI) and histamine-2 receptor antagonists (H2RA), questioning the safety of gastric acid suppression.
Objectives: To investigate PPI and H2RA and gastric cancer risk in two large independent study populations.
Methods: We conducted a nested case-control study within the Primary Care Clinical Informatics Unit (PCCIU) database. Each gastric cancer case was matched to up to five controls. Conditional logistic regression model was used to calculate odds ratios (OR) and 95% confidence intervals (CI). We also conducted a prospective cohort study within the UK Biobank in which medication use was identified from self-report at baseline and Cox regression was used to calculate hazard ratios (HR) and 95% CI.
Results: PCCIU contained 1,119 gastric cancer cases and 5,394 matched controls. PPI users had a higher gastric cancer risk (unadjusted OR=1.45, 95% CI 1.25, 1.68; fully adjusted OR=1.49, 95% CI 1.24, 1.80) but this was attenuated after excluding prescriptions in the 2 years before diagnosis (fully adjusted OR=1.13, 95% CI 0.91, 1.40). A similar pattern was seen for H2RA in the PCCIU database. UK Biobank contained 250 gastric cancers in 471,779 participants. PPI use was associated with increased gastric cancer risk (unadjusted HR=1.53, 95% CI 1.10, 2.12) but this was not apparent after adjustments (adjusted HR=1.28, 95% CI 0.86, 1.90) and further attenuated when excluding cancers within 2 years of baseline (adjusted HR=1.15, 95% CI 0.73, 1.82).
Conclusions: Overall, we observed evidence of associations between PPI/H2RA use and gastric cancer risk but these associations were sensitive to the duration of lag time used in the analysis, suggesting reverse causation.

4519 | Identifying microsatellite instability associated cancer patients in the veterans affairs healthcare system

Shahed Iqbal[1], Amanda M. De Hoedt[2], Kai-Li Liaw[1], Stephen J. Freedland[2,3], Mayur Amonkar[1], Deepti Aurora-Garg[1] and Zachary Klaassen[4,5]
[1]*Merck & Co., Inc., Kenilworth, NJ;* [2]*Veterans Affairs Health Care System, Durham, NC;* [3]*Cedars-Sinai Medical Center, Los Angeles, CA;* [4]*Medical College of Georgia, Augusta, GA;* [5]*Georgia Cancer Center, Augusta, GA*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Microsatellite instability (MSI) is a biomarker of active interest for targeted drug development for multiple cancers as patients with high MSI have been found to respond well to cancer therapy. Identifying MSI tested patients in electronic health records (EHR) is a difficult and complex process. In this era of precision medicine, it is important to understand and identify patients with biomarker data for epidemiologic and health outcomes research.

Objectives: To develop an optimal approach to identify MSI tested patients in the Veterans Affairs (VA) healthcare system.

Methods: A comprehensive list of 93 MSI-related 'search terms' and 47 CPT codes was generated by the study team that included oncologists, epidemiologists, bioinformatics and biomarker scientists. Structured and unstructured data (laboratory results, clinical and physician notes, etc.) in the VA healthcare database were searched using the CPT codes and search terms, respectively. From the identified records, a maximum of five randomly selected records for each search term or CPT code were manually reviewed to identify MSI tested cases. Frequently appearing MSI-related terms (e.g., MSI, microsatellite instability, etc.) found in the charts of MSI tested patients were used to further narrow down the search terms. A combination of CPT codes and search terms were explored for an optimal approach to identify MSI tested cases. Sensitivity (Sn), specificity(Sp), and positive predictive value (PPV) were calculated for all approaches.

Results: A total of 444 charts identified using 93 search terms were reviewed of which 129 (associated with 69 search terms) were found to be MSI tested cases. Another 198 charts identified using CPT codes were reviewed; 53 of which (associated with 26 CPT codes) were found to be MSI tested cases. In total, 642 unique patients were reviewed with 181 having MSI testing with at least one of the search terms or CPT codes. Search terms were narrowed down to 21 after reviewing all the frequently appearing MSI-related terms. Compared to 21 search terms (Sn: 40%, Sp: 85%, PPV: 52%,) or 26 CPT codes (Sn: 62%, Sp: 75%, PPV: 49%) separately, a combination of 21 search terms and 20 CPT codes more efficiently (Sn: 45%, Sp: 98%, PPV: 89%) identified MSI tested patients.

Conclusions: Most of the cases (89%) identified by a combination of search terms and CPT codes were found to be truly MSI tested. This is an efficient approach to identify and study MSI tested patients for outcomes of clinical interest. Similar approaches could identify patients with other biomarker data in other EHR systems where patients are not readily identifiable.

4663 | Characteristics and study eligibility of British lung cancer patients for clinical trials evaluating targeted therapies (TTS) or immune checkpoint inhibitors (ICIS)

Ard van Veelen[1,2], Shahab Abtahi[1], Patrick Souverein[2], Johanna H.M. Driessen[1], Olaf H. Klungel[2], Anne-Marie Dingemans[1], Robin van Geel[1], Frank de Vries[1,2] and Sander Croes[1]

[1]*Maastricht University Medical Centre, Maastricht, Netherlands;*
[2]*Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands*

Background: Inclusion and exclusion criteria used in clinical trials often lead to a homogeneous study-population. In this study we explored the characteristics of patients included in pivotal phase III clinical trials evaluating new drugs for patients with non-small cell lung cancer (NSCLC) with the characteristics of British patients diagnosed with lung cancer in daily practice.

Objectives: To study the characteristics and representativeness of British lung cancer patients compared to patients included in phase III clinical trials).

Methods: A retrospective study using the Clinical Practice Research Database (CPRD) GOLD was performed. All patients (N = 9239) with a first ever lung cancer registration (2014 - 2018) were included. Eligibility for inclusion was assessed for twelve clinical trials (evaluating osimertinib, alectinib, nivolumab, pembrolizumab, durvalumab, and atezolizumab) by applying all in- and exclusion criteria used in the clinical trials. Reasons for potential exclusion and the total number of unmet criteria were assessed for each study independently. Kaplan Meier analysis was used to compare overall survival between eligible and ineligible patients for each trial. In addition, Cox proportional hazards models were used to estimate hazard ratios and 95% confidence intervals (CI).

Results: The proportion of eligible patients based on for trials evaluating TTs was approximately 64.8%, while this was lower for studies evaluating ICIs (42.5%). Most patients would be eligible in the AURA3-study, for which 78.1% of the British patients population met inclusion criteria. While most patients would be excluded due to 1 or 2 criteria, the maximum number of unmet criteria was higher for studies evaluating ICIs. For all studies, the overall survival was longer for eligible patients compared to ineligible patients. Age and sex adjusted HRs ranged from 1.17 (95% CI = 1.14 - 1.20) to 1.24 (95% CI = 1.19 - 1.29).

Conclusions: A large proportion of British lung cancer patients would not have been eligible to be included in clinical trials evaluating drugs used in the treatment of NSCLC. A more lenient approach could be considered to increase the proportion of patients eligible for study participation and to better represent patients treated in daily practice.

4691 | Clinical value of oncology medicines in Europe: Is it different for conditionally approved medicines?

Lourens T. Bloem[1,2], Rosa E. Bot[1], Aukje K. Mantel-Teeuwisse[1], Menno E. van der Elst[2], Olaf H. Klungel[1,3], Hubert G.M. Leufkens[1] and Jarno Hoekman[1,4]

(EMA) may grant conditional marketing authorisation (CMA) based on less comprehensive data. EMA then requires post-approval trials to provide comprehensive data, after which standard marketing authorisation (SMA) can be granted. However, while addressing unmet medical need suggests a promise of added clinical value, it remains unknown whether that is achieved once comprehensive data are available.

Objectives: To determine whether CMA oncology medicines for which comprehensive data are available post-approval are associated with higher clinical value than SMA oncology medicines at approval.

Methods: We identified all CMA oncology medicines for which comprehensive data were available before March 2019. As reference group, we identified innovative non-CMA oncology medicines that had initially been granted SMA before March 2019 and were similar with regard to pharmacotherapeutic group and initial indication. For all medicines, we identified all pivotal trials that supported initial approval. For CMA medicines, we also identified all required post-approval trials. For each trial, we assessed the associated clinical value using the European Society for Medical Oncology Magnitude of Clinical Benefit Scale, which ranges 0-5 and indicates whether substantial clinical value is provided (≥4). We tested for differences between the groups with regard to maximum clinical value score available for each medicine and the chance that medicines provided substantial clinical value once comprehensive data were available post-approval (CMA) versus at approval (SMA). We therefore used the Wilcoxon Rank Sum test and calculated risk ratios (RR) and Wald 95% confidence intervals (CI), respectively.

Results: We identified 14 CMA and 22 SMA medicines. The median of the maximum clinical value of CMA medicines at approval was 3 (interquartile range [IQR] 2-3), and 13% provided substantial clinical value. Once comprehensive data were available, their maximum clinical value increased and was higher than that of SMA medicines (median 3 [IQR 2.5-4] vs. 3 [IQR 1-3], p=0.03), as was their chance to provide substantial clinical value (47% vs. 17%, RR 2.7 [95% CI 0.9-7.6]).

Conclusions: Compared to SMA oncology medicines, CMA oncology medicines are associated with higher clinical value and provide more often substantial clinical value once comprehensive data are available. This suggests that the EMA's use of the conditional approval pathway so far provides early access to clinically important oncology medicines.

4746 | Antiplatelet drug use and breast cancer risk in a prospective cohort study of postmenopausal women

Manon Cairat[1], Marie Al Rhamoun[2], Gianluca Severi[2], Marc Gunter[1], Laure Dossus[1] and Agnes Fournier[2]

[1]*International Agency for Research on Cancer, Lyon, France;* [2]*Centre de Recherche en Epidémiologie et Santé des Populations (CESP), équipe "Exposome, Hérédité, Cancer et Santé", Inserm UMR1018, Facultés de Médecine, Université Paris-Saclay, Université Paris-Sud, Gustave Roussy, Villejuif, France*

Background: By inactivating platelets and consequently blocking the release of growth and inflammatory factors, antiplatelet drugs (APDs), including low-dose aspirin and clopidogrel, could have anticancer properties. Epidemiological studies found consistent inverse associations between low-dose aspirin use and colorectal cancer risk whereas results for other cancers such as breast cancer (BC) are limited.

Objectives: We investigated the association between the use of low-dose aspirin or clopidogrel and BC incidence in the French E3N prospective cohort.

Methods: E3N includes 98,995 French women born between 1925 and 1950 and insured by a health insurance plan that covers mostly teachers. Information on lifestyle, anthropometric and reproductive factors, and medical history were collected biennially by self-questionnaires and matched with data from a drug reimbursement database pertaining to years 2004-2014. Women with at least two reimbursements in any 3-month period since 2004 were defined as ever exposed to APDs. Considering exposure as time-varying, multivariable Cox regression models were used to estimate hazard ratios (HRs) for the association of APD use with BC, overall and by BC subtypes. Effect modification by breast cancer risk factors and comorbidities that might be associated with APD use was also assessed.

Results: In the current analysis, 62,390 postmenopausal women were followed between 2004 and 2014 (9 years on average, starting at a mean age of 63 years; 2,887 BCs). Of them, 17% were exposed to low-dose aspirin and 3% to clopidogrel during follow-up. Use of low-dose aspirin use was not associated with BC risk [HR= 1.03 (0.91 - 1.17) for ever exposed compared to non-exposed women], except when it lasted more than four years [HR=0.68 (0.47 - 0.98)]. Clopidogrel use was associated with an increased breast cancer risk [HR= 1.30 (1.00 - 1.67)], regardless of the duration of use. This increase in risk was significant only for estrogen receptor negative (ER-) BC [HR_{ER+}= 1.14 (0.83 - 1.55), n exposed cases=44; HR_{ER-}= 3.16 (1.72 - 5.79), n exposed cases=13; P homogeneity=0.01].

Conclusions: In this large prospective cohort of postmenopausal women, low-dose aspirin use for more than four years was associated with a decreased risk of BC, whereas clopidogrel was associated with an increased risk of ER- BC, regardless the duration of use.

4777 | The potential of claims data for long-term follow-up of breast cancer patients in Germany

Miriam Heinig[1] and Ulrike Haug[1,2]

[1]*Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany;* [2]*University of Bremen, Bremen, Germany*

Background: Population-based data on long-term treatment patterns and clinical outcomes in cancer patients are important but hardly available from German cancer registries.

Objectives: Exemplified by breast cancer (BC) patients, we aimed to explore the potential of German claims data for providing long-term follow-up information on cancer patients.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We used the German Pharmacoepidemiological Research Database (GePaRD) containing claims data from four statutory health insurances with information on ~25 million persons. Based on previously developed algorithms using ICD-10 codes, we identified patients newly diagnosed with BC in 2008 and classified them into three groups: no affected lymph nodes/metastasis (noNM), affected lymph nodes only (onlyN) or distant metastasis (M) at diagnosis. The cohort was followed up until end of 2016 or death. We characterized the groups regarding initial and subsequent therapies (surgery, medical therapy and radiotherapy), metastases and deaths occurring during follow-up.

Results: After exclusion of patients switching health insurance during follow-up (9% of the initial cohort) we included 11,717 BC patients diagnosed in 2008 (noNM: 82%, onlyN: 12%, M: 7%) with a mean age of 63 years (median follow-up: 8.4 years). During the observation period, 11% of the cohort received no breast surgery (group M: 21%), 28% received more than one surgery (second surgery in first year: 81%; later: 19%) and 29% had a mastectomy (in first year: 91%, only later: 9%). Of the total cohort, 8% received neoadjuvant therapy and 7% received both neoadjuvant and adjuvant (systemic) therapy. Regarding systemic therapy, 7% ever received monoclonal antibodies, 74% ever received hormone therapy, and 52% never received chemotherapy (group noNM: 92%). Of all patients, 28% never received radiotherapy. Overall, 25% of the cohort died (group M: 22%).

Conclusions: Claims data provide valuable information on the long-term course and treatment of cancer patients, avoiding substantial loss-to-follow-up and incomplete reporting of therapies. Combining claims data with cancer registry data containing detailed tumor information may create synergies that should be explored.

4847 | Approximating line of treatment using drug exposure data and clinical information of patients with metastatic breast cancer using U.S. electronic health record data

Thibaut Sanglier[1], Jinjoo Shim[1], M.K. Downer[2], Carlos Flores[2] and Patricia Luhn[2]

[1]*F.Hoffmann-La Roche, Basel, Switzerland;* [2]*Genentech Inc., South San Francisco, CA*

Background: In oncology, the number of lines of treatment (LoT) since metastatic cancer diagnosis is an important predictor of subsequent outcomes. Yet accurate LoT information is often unavailable from healthcare claims or electronic health records (EHR) data and is challenging to estimate. Most studies use the number of unique antineoplastic regimens (ANR) observed since diagnosis as a proxy for LoT. However, for metastatic breast cancer (mBC) this may lead to substantial misclassification; changes in ANR may occur for reasons besides worsening disease (e.g. toxicity, safety). EHRs with data on timing of both ANR changes and clinical events can help assess the clinical relevance of ANR changes to estimate LoT.

Objectives: To identify changes in ANR and estimate their association with clinical events in a cohort of patients with mBC.

Methods: Using data from the US-based Flatiron Health EHR-derived de-identified database, we selected patients diagnosed with mBC between January 1, 2011 - October 30, 2019 treated with at least two ANRs after mBC diagnosis. The cohort was stratified by mBC subtype: HR+/HER2-, HER2+ and TNBC. A single ANR included any exposure to antineoplastic drug recorded within the 28 days following the first drug initiation, subsequent incident drug exposure recorded more than 28 days after the ANR initiation defined the subsequent ANR. Any drug change in an ANR defined a treatment event. Notes in the medical records suggestive of disease worsening (e.g. progression of the disease) between first treatment initiation of the prior ANR +14 days and 14 days after first treatment initiation of the subsequent ANR defined a clinical event.

Results: 6551 patients (4453 HR+/HER2-, 1348 HER2+, 710 TNBC) mBC patients were included. The frequency ranges of the five most frequent treatment events grouped by drug class were [411-1060], [114-296] and [65-358] and the ranges of probabilities to observe a clinical event were [51%-89%], [13%-85%] and [9%-86%] for the HR+/HER2-, HER2+ and TNBC cohorts respectively.

Conclusions: The probability of observing concurrent clinical and treatment events varied, even for the most common treatment events. These results mostly reflect clinical guidelines and suggest drug exposure-based algorithms counting number of ANR from mBC as proxy for LoT may lead to substantial misclassification. Identifying common treatment events unlikely to be associated with concurrent clinical events can help to improve these algorithms and reduce misclassification.

4862 | Performance of QRISK-3 scores in predicting cardiovascular disease in adult cancer survivors compared to matched cancer free controls

Helen Strongman[1], Emily Herrett[1], Rod Jackson[2], Michael Sweeting[3], Alexander R. Lyon[4], Susannah Stanway[5], Claire Lawson[3], Umesh Kadam[3], Liam Smeeth[1] and Krishnan Bhaskaran[1]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom;* [2]*University of Auckland, Auckland, New Zealand;* [3]*University of Leicester, Leicester, United Kingdom;* [4]*Imperial College London, London, United Kingdom;* [5]*Royal Marsden Hospital, London, United Kingdom*

Background: Survivors of many site-specific cancers have elevated medium to long term risks of coronary heart and stroke compared to the general population. QRISK-3 scores, which inform statin prescribing decisions in the UK, may therefore underpredict coronary heart and cerebrovascular disease in cancer survivors.

Objectives: To assess the predictive performance of the QRISK-3 tool in predicting coronary heart and cerebrovascular disease in cancer survivors.

Methods: We conducted a cohort study using linked Clinical Practice Research Datalink primary care, hospital, cancer registration and death registration data from 1990 to 2015. We identified adult cancer survivors with a first cancer diagnosis for one of the 20 most common cancers and who were followed-up for at least one year before and after diagnosis. These were matched by age, gender, practice and index date

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

to a cancer-free comparison group. We removed individuals with pre-existing cardiovascular disease and current statin users, and calculated QRISK-3 scores one year after the index date in both groups. Coronary heart and cerebrovascular disease outcomes that occurred during follow-up were identified using Read and ICD-10 codes. We plotted 10 year predicted and observed risks for each decile of predicted risk to assess calibration using a naïve Kaplan-Meier approach to estimate observed risks. We used the Harrell's C statistic to assess discrimination.

Results: One year after cancer diagnosis, there was close correspondence between predicted and observed 10-year risk in cancer survivors except for a degree of overprediction at higher deciles of risk (1.9% and 0.3% underprediction in males and females respectively in the lowest decile; 13.4% and 9.8% overprediction in males and females respectively in the highest decile). In cancer free controls, similar patterns were observed with tighter calibration (0.7% and 0.1% underprediction in males and females respectively in the lowest decile; 7.6% and 4.1% overprediction in males and females respectively in the highest decile). Overprediction in each group was highest in older individuals. The Harrell's C statistic was 0.67 and 0.68 in male cancer survivors and controls respectively and 0.77 in females in both groups.

Conclusions: We observed no underprediction of coronary heart and cerebrovascular disease by QRISK-3 scores in cancer survivors and cancer free controls, but some overprediction at higher deciles which was strongest in cancer survivors and for older people. This may be due in part to depletion of susceptibles and poorer performance of QRISK3 in older people.

4873 | Association of surgical complications with in-hospital mortality among patients undergoing major pancreatic resection

Joseph Guilfoyle[1], Neal Bhutani[2], Stephen Johnston[1], Hari Dwarakanathan[3], Anuprita Patkar[4] and Robert CG Martin[5]

[1]Johnson and Johnson, New Brunswick, NJ; [2]University of Louisville, Louisville, KY; [3]Mu Sigma, Bangalore, India; [4]Ethicon, Somerville, NJ; [5]University of Louisville, Louisville, KY

Background: Surgical complications are common in major pancreatic resection. Whereas prior research has associated surgical complications with increased length of stay and costs for the hospitalization during which the surgery was performed, little research has been published on whether such complications are associated with increased risk of mortality.

Objectives: To examine the association of surgical complications with the incidence of in-hospital mortality among patients undergoing distal pancreatectomy (DP) or pancreaticoduodenectomy (PD).

Methods: Retrospective, cross-sectional analysis of U.S. data from the Premier Healthcare Database. Included patients were aged ≥18 years undergoing pancreatic resection between October 2015 and March 2019 (first=index admission). Surgical complications (intra/post-operative) were measured during the index admission using secondary diagnosis codes; complications were compiled based on expert clinical knowledge and included infective, cardiac, pulmonary, genitourinary and several other groupings. The primary study outcome was in-hospital mortality (discharge status of 'expired') during the index admission. Multivariable generalized estimating equations were used to compare the adjusted risks of mortality between patients with vs. without ≥1 surgical complication, accounting for hospital level-clustering and patient/surgeon/hospital characteristics; recycled prediction was used to calculate absolute and between-group risk differences.

Results: A total of 5,931 patients underwent PD and 4,010 underwent DP. During the index admission, 3,428 (57.8%) PD patients and 1,648 (41.1%) DP patients developed ≥1 surgical complication; 170 (2.9%) PD and 72 (1.8%) DP patients experienced mortality. As compared with patients with no surgical complications, the relative risk of mortality among patients with ≥1 surgical complication was 15.0 for PD (risk difference=4.2 percentage points [95% CI=3.4-4.9], 4.5% vs 0.3%, p<0.0001) and 10.3 for DP (risk difference=2.8 percentage points [95% CI=2.0-3.6], 3.1% vs 0.3%, p<0.0001). When examining individual surgical complication groups, cardiac, genitourinary, and infective complications had the strongest associations with mortality in both PD and DP.

Conclusions: In-hospital mortality rates were dramatically elevated among patients who experienced surgical complications during PD or DP. Measures to decrease the incidence and severity of surgical complications may help to decrease the risk of in-hospital mortality among patients undergoing major pancreatic resection.

4934 | Hydrochlorothiazide and risk of melanoma subtypes

Laurel A. Habel[1], Ninah Achacoso[1], Bruce Fireman[1], Sidsel Arnspang Pedersen[2] and Anton Pottegard[3]

[1]Kaiser Permanente Northern California, Oakland, CA; [2]University of Southern Denmark, Odense, Denmark; [3]Institut for Sundhedstjenesteforskning Syddansk Universitet, Odense, Denmark

Background: Hydrochlorothiazide (HCTZ), a common diuretic known to be photosensitizing and previously associated with non-melanoma skin cancer, was recently reported to be associated with two melanoma subtypes, nodular and lentigo, among residents of Denmark.

Objectives: Our goal was to examine whether Danish findings could be replicated in a US cohort, using a similar study design and analysis.

Methods: Among non-Hispanic White enrollees of Kaiser Permanente Northern California, we conducted an analysis of 9,176 melanoma cases and 264,781 controls, matched on age, sex and time in health plan. We examined use of HCTZ prior to cancer diagnosis (cases) or comparable date for controls, categorized as never use, ever use and high use (≥50,000 mg). Electronic health records provided data on prescriptions, cancer diagnoses, and covariates. Conditional logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs), adjusted for education, income and number of dermatology, internal medicine and urgent care visits.

Results: We observed a small increase in risk of melanoma, all types combined, associated with high use (≥50,000 mg) of HCTZ (OR=1.11,

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

95% CI 1.00-1.23) and no evidence of a dose-response. Risk was more elevated for lentigo subtype (OR=1.57, 95% CI 1.01-2.42). The somewhat elevated risk for nodular subtype was not statistically significant (OR=1.22, 95% CI 0.78-1.90). There was very little association of high use with the superficial spreading subtype (OR=1.05, 95% CI 0.80-1.37).

Conclusions: Our findings support a recent report of an association between high use of HCTZ and increased risk of the lentigo subtype of melanoma.

5054 | Site-specific cancer risk from exposure to cobalt alloys in orthopedic implants or cobalt in occupational settings: A systematic review and meta-analysis

Chantal Holy[1], Shumin Zhang[1], Laura Perkins[2], Laurence B. Katz[3], Jason Brown[4], Luca Orlandini[5], Gion Fessel[5], Behrooz Nasseri-Aghbosh[6], Gary Eichenbaum[1], Natalie S. Egnot[7] and Paul M. Coplan[1]

[1]Johnson & Johnson, New Brunswick, NJ; [2]Abbott Vascular, Santa Ana, CA; [3]LifeScan, Malvern, PA; [4]Medtronic, Minneapolis, MN; [5]Smith & Nephew, Baar, Switzerland; [6]Stryker, Elstree, United Kingdom; [7]Cardno ChemRisk, Pittsburgh, PA

Background: The European Commission recently up-classified metallic cobalt as presumed human carcinogenic. This decision was based primarily on two rodent inhalation studies of metallic cobalt. This up-classification raised questions regarding risk posed by exposure to implants containing cobalt alloys and in work places.

Objectives: Evaluate the risk of site-specific cancer associated with exposure to implants containing cobalt alloys and occupational exposures.

Methods: A systematic review in Pubmed and meta-analysis were performed to evaluate site-specific cancer risks in patients with total joint replacements (TJR) or workers in occupational cohort (OC) exposed to particulate cobalt. These study types were selected as they represent possible long term and high-level exposures. Estimates for organ-specific cancers were extracted, grouped in 27 distinct cancer types, and aggregated using random-effects models (REM). Models were stratified by metric (Standardized Incidence Ratio (SIR) vs Standardized Mortality Ratio (SMR) or other rate ratios) and study type (registry vs database vs occupational cohort (OC)).

Results: 21 TJR and 12 OC studies, including 979,262 people with average 7.8 years follow-up were included. Of 27 cancer types assessed, 3 had pooled estimates significantly lower in cobalt-exposed groups (lung/lower respiratory tract, stomach and intestinal cancers) while 2 were higher in the cobalt exposed groups: prostate cancer (estimate = 1.08 CI: 1.03-1.13: SIR = 1.10 (1.05-116), SMR = 1.07 (0.80-1.43)) and myeloma (estimate= 1.12, CI: 1.05-1.19, 13 out of 14 data points reported SIR, no SMR data).

Conclusions: Of the 27 cancers assessed, 22 were not different from, and 3 were below the null. Risk for detection, but not mortality, was slightly greater than the null for prostate cancer, suggesting detection bias. For myeloma, risk of detection was slightly increased. Myeloma, often detected via blood work from regular follow-up, is prone to detection bias through incidental finding, more so than many other cancer types. Findings for these 2 cancer types resulted in weak associations and were likely not clinically relevant.

5092 | Patterns of recurring colorectal polyps and risk of colorectal cancer in commercially insured US adults

Laura L. Hester[1], Christopher Knoll[2] and Dina M. Gifkins[2]

[1]Janssen R&D, LLC, Titusville, NJ; [2]Janssen R&D, LLC, Raritan, NJ

Background: Limited evidence is available on whether patients with frequently recurring colorectal polyp diagnoses (dx) have an increased risk of colorectal cancer (CRC). Understanding the incidence of recurrent colorectal polyp dx and transformation to CRC over time can aid in interception efforts targeting high-risk patients.

Objectives: To characterize patients with recurrent colorectal polyps and to estimate the risk of recurrent polyp dx and transformation to CRC over time.

Methods: Using Optum© Clinformatics® Datamart commercial claims (2001-2018), we identified US patients with (1) an initial colorectal polyp dx with a polypectomy in the prior 30 days, (2) >=365 days prior continuous enrollment, (3) no colorectal polyp or CRC history, and (4) no polypectomies or CRC dx 60 days postdiagnosis. Five-year risks of 2nd and 3rd polyp dx subsequent to the initial polyp dx were calculated using competing risk models with CRC as a competing risk. To generate hypotheses on risk factors for recurring polyp dx, we compared the prevalence of prior conditions, drugs, and procedures among patients with only 1 vs 3+ polyp dx in 5 years using standardized differences. Additionally, we assessed risk of CRC, defined with 2 primary malignant colorectal lesion codes 90 days apart, over a 5-year period from first and subsequent polyp dx using Cox proportional hazards models. Screening patterns were also assessed.

Results: Over 1.5 million patients with a colorectal polyp were identified during the study period. Within 5 years of an initial polyp dx, the risk of a 2nd polyp dx was 21%, and the risk of a 3rd polyp dx was 3%. Patients at the highest risk for CRC transformation with 3+ subsequent polyp dx compared to those with only 1 polyp dx were more likely to be older (median 67 v 61 yrs), male (61% v 55%), and have baseline conditions such as abnormal keratinization (17% v 10%), eye lesions (28% v 19%), and gall bladder disorders (14% v 8%). Overall, the 5-year risk of CRC dx among all patients was 1.1%, which increased to 2.1% in a subset with a subsequent polyp dx.

Conclusions: CRC risk increased with subsequent polyps, which were experienced by 1 in 5 patients within 5 years of an initial polyp. Patients with 3+ polyps dx in 5 years had a greater prevalence of diseases known to occur in the genetic condition, Lynch Syndrome, which has a high CRC risk and is often undiagnosed until CRC lesions are tested. Current efforts to develop a machine learning prediction model will aid in earlier identification of persons who could benefit from CRC chemoprevention, like those with Lynch Syndrome, and the design of future interventional studies.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 5115 | Incidence and management trends for cervical HSIL in a large US cohort from 2008 through 2018

Katherine C. Hughes[1], Timothy Herring[2], Jennifer Song[1], Robert Gately[1], Lindsay Nowak[3], Judy Wong[1], Mark Twyman[2], Prakash Bhuyan[2] and John D. Seeger[1]
[1]*Optum Epidemiology, Boston, MA;* [2]*Inovio Pharmaceuticals, Inc., Plymouth Meeting, PA;* [3]*None, Tonawanda, NY*

Background: Cervical HSIL is the precursor condition to invasive cervical cancer, which remains one of the most prevalent causes of morbidity and mortality, respectively, worldwide for women in the 21st century. Several improvements in the standard-of-care have occurred, such as the introduction of human papillomavirus (HPV) prophylactic vaccines and improved cervical cancer screening approaches. This analysis describes the observed overall impact of these improvements on the occurrence of cervical HSIL and frequency of initial surgical management.
Objectives: In a U.S. commercially insured population, 1) to longitudinally describe the detected occurrence of HPV-16/18 vs. non-HPV-16/18 associated cervical HSIL, and 2) to describe what portion of women received surgical management versus non-interventional medical monitoring.
Methods: Between 2008 and 2018 within the Optum Research Database, we identified a cohort of women aged 18+ with health insurance claims for cervical HSIL and described their management patterns.
Results: Among 65,527 women with cervical HSIL identified over the 10-year study period, 47,067 (72%) received HSIL initial treatment (surgery) while 18,460 (28%) did not. Initially, the number of incident cervical HSIL cases per year declined from a high of 9,470 in 2008 to 4,681 in 2014. Then, in the last three full years of the study period the annual number of HSIL cases appeared to stop declining (4,952, 5,357, and 5,354 cases in 2015, 2016, and 2017, respectively). The proportion of incident cervical HSIL cases that received initial surgical treatment for their HSIL diagnosis slightly increased from 68% in 2008 to 73% in 2017.
Conclusions: An initial decline in the occurrence of detected cervical HSIL was observed, which likely represents the implementation of improved adherence to screening guidelines as well as the impact of HPV prophylactic vaccination. The stabilization in the number of detected HSIL cases in the final years of the study period indicates that, in spite of improved screening approaches, the use of prophylactic vaccines, and surgical treatment, a significant incidence of cervical HSIL persists in the U.S. which can lead to and thus does not eradicate cervical cancer.

Disease Epidemiology/Clinical Course -> Cardiovascular

2392 | Uncontrolled blood pressure and therapeutic inertia in treated hypertensive patients: A descriptive cohort study in clinical practice research datalink (CPRD)

Céline Darricarrère[1], Marc Bénard[2], Stéphanie Bricout-Hennel[1], Caroline Louis[1] and Emmanuelle Jacquot[1]
[1]*Servier, Suresnes, France;* [2]*Aixial, Boulogne-Billancourt, France*

Background: Hypertension is a major and fast-growing cause of cardiovascular (CV) diseases and deaths. Treatment and control of this condition are crucial to reduce CV events and related burden. One of the identified factors contributing to uncontrolled hypertension is therapeutic inertia, which is the failure of health-care provider to modify therapy when blood pressure (BP) targets are not reached.
Objectives: To quantify uncontrolled BP over time and therapeutic inertia in UK patients treated for hypertension in Primary Care.
Methods: A retrospective cohort of patients diagnosed with primary hypertension and receiving antihypertensive drugs from January 2015 to June 2017, was created from the CPRD (GOLD). Patients with secondary hypertension were excluded. Index date (ID) is the first prescription of hypertensive drug during study period. Patients were followed for 18 months. Primary outcomes were proportions of patients with uncontrolled BP (one BP record, Systolic ≥ 140 mmHg or Diastolic ≥ 90 mmHg) at ID and over time; time to first BP control (one BP record Systolic < 140 mmHg and Diastolic < 90 mmHg) in patients uncontrolled at ID and proportion of therapeutic inertia defined as 2 consecutive uncontrolled BP records with no treatment change.
Results: 581 260 treated hypertensive patients (mean age 67.8 years, 51.3% women) were included, among whom 37.2% (N=216 014) had an uncontrolled BP record at ID, 32.6% had a controlled BP record (N= 189 291) and 30.3% (N=175 955) did not have any BP record. At ID, 516 231 patients (88.8%) were prevalent users of HT drugs and mean duration since first antihypertensive medication prescribed was 8.3 years. The mean number of BP records per patients during follow-up was 2.1 at 1 year, with 1.1 and 1.0 for uncontrolled and controlled values respectively. Over a median follow-up of 18 months, 59.2% of the patients had at least one uncontrolled BP record and 12.8% of patients did not have any BP record. Focusing on uncontrolled population at ID (N=216 014), 72.9% had at least one uncontrolled BP record during the follow-up and 28.3% had only uncontrolled BP records. Therapeutic inertia occurred at least once for 55.7% of the uncontrolled population. However BP control was reached for 61.5% of the uncontrolled population at ID, within 185 days in median.
Conclusions: This cohort study showed that recording of BP measures in hypertensive patients' medical record is poor. Based on this low number of measures, uncontrolled BP and therapeutic inertia remain common.

2465 | Identification of an appropriate time window for the exclusion of prevalent cases recorded following registration with the clinical practice research datalink

Thomas P. Leahy[1], Cormac Sammon[1] and Sreeram Ramagopalan[2]
[1]*PHMR Ltd, London, United Kingdom;* [2]*London School of Economics and Political Science, London, United Kingdom*

Background: Defining incidence cases of a disease in primary electronic health records such as the Clinical Practice Research Datalink (CPRD) is complicated by the lack of patient history prior to registration with a CPRD-registered practice. In the CPRD it has been shown that prevalent conditions are often recorded shortly after registration with a GP practice and therefore to avoid the inappropriate inclusion of these individuals as incident cases, first diagnoses recorded in a specified period post registration are typically excluded. However, CPRD publications rarely report how the time period post-registration is chosen, with many appearing to use a default choice of 12 months.

Objectives: To compare approaches to determine the length of the period post-patient registration required to avoid the inclusion of non-incident cases in a study population.

Methods: As a case study, all patients with a first recorded non-valvular atrial fibrillation (NVAF) diagnosis in the CPRD between 2006 and 2015 were identified. Five different approaches were then used to choose a period post-registration to exclude patients (i) a standard 12-month period (ii) visual inspection of a plot of the incidence of the condition over time since registration, (iii) visual inspection of a plot of the cumulative sum (CUMSUM) over time since registration, (iv) a variance changepoint method to identify the point at which the incidence variance changes post-registration, and (v) a reverse time series trend approach. The impact of each approach on the size of the incident study population was assessed.

Results: In the period 2006 to 2015 there were 48638 patients with a NVAF diagnosis. The use of a 12-month period under approach (i) resulted in a study population of 43992. Approaches (ii), (iii), (iv) and (v) resulted in the identification of 7 months, 3 months, 3 months and 5 months as being the suitable exclusion periods, respectively. Application of these periods resulted in study populations of 45439, 46825, 46825 and 46080 respectively. These reflected relative increases in the study population of 3.29%, 6.44%, 6.44% and 4.75% respectively.

Conclusions: Using the standard 12-month period post-patient registration may unnecessarily reduce the study population size. We suggest alternative approaches are used which at a minimum involve visual inspection of relevant plots of the incidence over time since registration and potentially use objective, data driven approaches to choose the cut-off. Sensitivity analyses could be used to illustrate any impact of using periods of differing length.

2564 | Transatlantic differences in healthcare systems captured by large administrative databases: Assessing the burden of COPD in patients admitted for heart failure

Claudia Gulea[1], Rosita Zakeri[2] and Jennifer K. Quint[1]

[1]Imperial College London, London, United Kingdom; [2]King's College London, London, United Kingdom

Background: Patients hospitalized for heart failure (HF) are at increased risk of unplanned readmission if they have comorbid COPD in addition to HF. It is unclear whether regional variation in readmission risk estimates is due to patient characteristics alone or additionally influenced by healthcare system differences.

Objectives: To compare the impact of comorbid COPD on short-term readmission risk among patients with HF using patient-level data from two nationally-representative databases.

Methods: We identified patients with an index hospitalisation for HF in the National Readmissions Database (NRD) in the US (1/1/12-30/11/12) and in Hospital Episode Statistics in the UK (1/1/12-30/11/13). To ensure valid comparisons, we standardised diagnosis definitions across datasources using validated ICD codelists. Using Cox regression we assessed 30-day readmission risk associated with COPD in individual and merged datasets, allowing adjustment for confounding factors including age, gender, length of stay [LOS] and comorbidities. As NRD did not provide data on smoking status, medications or out-of-hospital mortality status, we did not include these in the merged dataset.

Results: Of 225,160 patients in the US and 10,171 in the UK, one quarter had COPD. Patients in the US were younger, with higher prevalence of comorbidities, such as coronary artery disease and hypertension. In adjusted analyses COPD was positively associated with 30-day readmission risk in both the UK (HR: 1.18, 95% CI 1.06 to 1.3) and US (HR 2.01, 95%CI 1.96 to 2.06, p-value for country interaction <0.001). In the US, baseline in-hospital mortality was lower (2.8% vs. 9.3%) and LOS was shorter (median, days [IQR]: 4 [3- 7] vs. 7 [3-14]) than in the UK. Proportions of circulatory (50% US vs. 41% UK) and respiratory readmissions (16% US vs. 26% UK) also differed.

Conclusions: Using national administrative datasources from the US and UK, we identified diverging patterns of healthcare utilisation and in-hospital mortality among patients with HF, which were incompletely explained by differences in patient characteristics. We found that COPD carries a higher readmission tarrif in the US compared to the UK, suggesting a lower threshold for readmission in the US, while late disease detection and coding practices tuned to capture more severe patients may underlie the high baseline in-hospital mortality in the UK. Future analysis of differences in diagnostic pathways and reimbursement elements may reveal pertinent practice-related factors that affect patient outcomes.

4013 | Cumulative exposure to bisphosphonates and risk of cardiovascular and cerebrovascular events

Elena Olmastroni[1], Manuela Casula[1,2], Federica Galimberti[1], Elena Tragni[1], Giovanni Corrao[3,4], Lorenza Scotti[5] and Alberico L. Catapano[1,2]

[1]Epidemiology and Preventive Pharmacology Service (SEFAP), Department of Pharmacological and Biomolecular Sciences, University of Milan, Milan, Italy; [2]IRCCS MultiMedica, Sesto S. Giovanni (MI), Italy; [3]National Centre for Healthcare Research & Pharmacoepidemiology, Milan, Italy; [4]Laboratory of Healthcare Research & Pharmacoepidemiology, Department of Statistics and Quantitative

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods, University of Milano-Bicocca, Milan, Italy; [5]Unit of Biostatistics, Epidemiology, and Public Health, Department of Statistics and Quantitative Methods, University of Milano-Bicocca, Milan, Italy

Background: Although bisphosphonates have been suggested to protect against atherosclerotic cardiovascular (CV) events, evidence is still conflicting.

Objectives: We aimed at investigating the effect of bisphosphonates on cardiovascular and cerebrovascular events.

Methods: We carried out a retrospective cohort study selecting from administrative databases of Lombardy (Italy) all patients aged> 40 years with a first prescription for bisphosphonates (index date) between 2003/01/01 and 2006/12/31. Subjects were followed from the index date until the date of the first hospitalization for cardio-cerebrovascular event, death, migration, or end of follow-up (2012/12/31), whichever occurred first. Exposure to bisphosphonates was characterized based on cumulative doses (proportion of days covered, PDC). Treatment's adherence was classified as low (PDC<41%), intermediate (PDC 41% and 80%), or high (PDC>80%). Cox models were fitted to estimate the association between time-dependent exposure to bisphosphonates and cardiovascular and cerebrovascular events (adjusted hazard ratios [HRs] and 95% confidence intervals). The model was adjusted for age, sex, comorbidities, and concomitant treatments.

Results: Among 82,704 incident bisphosphonates users (females 87.0%; mean age±SD 70.7±10.6 years), we identified 13,337 individuals (16.1%) with a first hospitalization for cardiovascular and cerebrovascular event, occurred on average (SD) 3.5 (2.3) years after the index date. Compared with individuals with an exposure <41% of follow-up, those exposed for 41% and 80% or more than 80% showed HRs of 0.95 [0.91-0.99] and 0.75 [0.71-0.81], respectively. In the subanalysis based on type of event, a PDC>80% was associated with a reduction of both cardiovascular and cerebrovascular events (HRs 0.75 [0.68-0.83] and 0.76 [0.70-0.83], respectively). The protective effect was confirmed both in the analyses stratified by sex and age classes, and in those performed at 1 and 3 years of follow-up.

Conclusions: These results suggested a strong CV risk reduction (up to 25%) with increasing number of days covered by bisphosphonate treatment. Although further studies to investigate possible mechanisms are warranted, it is important to consider bisphosphonates, and a strict adherence to this treatment, as having a potential effect also in the prevention of cardiovascular events.

4017 | Apolipoprotein B and risk of cardiovascular disease: A meta-analysis of randomized controlled trials

Federica Galimberti[1,2], Alberico L. Catapano[1,3], Julius L. Katzmann[2,4], Arjen J. Cupido[2,5] and Brian A. Ference[2]

[1]*University of Milan, Department of Pharmacological and Biomolecular Sciences, Epidemiology and Preventive Pharmacology Service (SEFAP), Milan, Italy;* [2]*University of Cambridge, Department of Public Health and Primary Care, MRC/BHF Cardiovascular Epidemiology Unit, Cambridge, United Kingdom;* [3]*IRCCS MultiMedica, Sesto S. Giovanni (MI), Italy;* [4]*Department of Cardiology, University Hospital Leipzig, Leipzig, Germany;* [5]*Amsterdam UMC, University of Amsterdam, Department of Vascular Medicine, Amsterdam, Netherlands*

Background: Recent evidence from Mendelian randomization studies suggest that the clinical benefit of any lipid-lowering therapy should be proportional to the absolute change in apolipoprotein B (apoB) containing lipoproteins. This finding implies that the clinical benefit of any lipid-lowering therapy should be proportional to the absolute change in apoB.

Objectives: We sought to compare and to estimate the magnitude of the expected clinical benefit per unit reduction in apoB for several classes of lipid-lowering therapies.

Methods: We conducted a study-level meta-analysis of randomized trials evaluating 6 different classes of lipid-lowering therapies (statins, ezetimibe, PCSK9-inhibitors, CETP-inhibitors, niacin, and fibrates). We included all randomized trials reporting apoB levels and cardiovascular (CV) outcomes, with at least 1000 participants and 1-year follow-up. The primary outcome for this meta-analysis was major CV events - defined as the first occurrence of CV death, non-fatal myocardial infarction, stroke or coronary revascularization. We estimated the relative risk (RR) of major CV events standardized for a 30 mg/dl reduction in apoB using fixed effect inverse-variance weighted meta-analysis (adjusted for study duration) separately for each class of therapy and in a combined analysis including all classes of lipid-lowering therapies. Heterogeneity between the different classes of lipid-lowering therapies was measured with the I2 statistic.

Results: A total of 25 trials that enrolled 285,241 participants (mean age: 63.3 years; female sex: 24.7%) who experienced 40,244 first major CV events were included. The mean baseline apoB level was 93.9 mg/dL. The mean absolute difference in apoB between the treatment and comparison groups at one year was 24.1 mg/dL. The overall RR per 30 mg/dL reduction in apoB levels was 0.79 (95% confidence intervals (CI) 0.77-0.81) for major CV events, consisting of separately significant reductions in non-fatal myocardial infarction (RR 0.76; 95% CI 0.73-0.79), in coronary revascularization (0.78; 0.73-0.82), in stroke (0.79; 0.76-0.81) and in CV death (0.87; 0.82-0.92). No significant heterogeneity was detected.

Conclusions: All the lipid-lowering therapies are associated with very similar reductions in the risk of major CV events per unit change in apoB, suggesting that the clinical benefit may be proportional to the achieved absolute reduction in apoB, regardless of the observed changes in other lipids. These finding can be used to inform the design of randomized trials evaluating novel lipid-lowering therapies.

4022 | Evaluation of the effect of omega-3 polyunsaturated fatty acids supplementation on cardiovascular outcomes: An updated meta-analysis of randomized controlled trials

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Elena Olmastroni[1], Manuela Casula[1,2], Marta Gazzotti[1], Federica Galimberti[1], Elena Tragni[1], Alberto Zambon[3] and Alberico L. Catapano[1,2]

[1]*Epidemiology and Preventive Pharmacology Service (SEFAP), Department of Pharmacological and Biomolecular Sciences, University of Milan, Milan, Italy;* [2]*IRCCS MultiMedica, Sesto S. Giovanni (MI), Italy;* [3]*Department of Medicine-DIMED, University of Padua, Padua, Italy*

Background: There has been a great deal of controversy about the role of dietary supplementation with omega-3 long-chain polyunsaturated fatty acids (n-3 PUFA) eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in the prevention of cardiovascular (CV) disease.

Objectives: This meta-analysis aimed at investigating the effect of n-3 PUFA administration on CV events in all published randomized clinical trials (RCTs), updating the available results with the recently published REDUCE-IT trial.

Methods: Data search was carried out using PubMed, Cochrane and EMBASE (inception - March 2019). Inclusion criteria were: (1) RCTs; (2) patients had used n-3 PUFA at least 1 gram/day dosage for at least 1 year; (3) effects on outcomes (all-cause mortality, cardiac death, major adverse cardiovascular events [MACE], fatal/nonfatal myocardial infarction [MI], and fatal/nonfatal stroke) reported. Odds ratios (ORs) with 95% confident intervals (95%CI) were used as summary statistics.

Results: Overall, supplementation of n-3 PUFA was associated with a significant reduction of 13% of the risk of cardiac mortality (OR 0.87 [95%CI 0.79-0.97]) and of 22% of the risk of MI (OR 0.78 [95%CI 0.65-0.94]. In subgroup analyses by type of patients' prevention the risk reduction of cardiac mortality and MI associated with the supplementation of n-3 PUFA was confirmed only in RCTs that enrolled patients in secondary prevention (-23% and -45%, respectively). Stratified analyses based on doses of n-3 PUFA, highlight that only the administration of more than 1 gram per day of n-3 PUFA seems to be effective in reducing the risk of cardiac death (OR 0.71 [95%CI, 0.54-0.95]), MACE (OR 0.68 [95%CI, 0.47-0.99]), and MI (OR 0.67 [95%CI, 0.59-0.77]). In subgroup analyses by type of administration, EPA+DHA provision was only associated with a statistically significant risk reduction of cardiac death compared with EPA administered alone (OR 0.87 [95%CI, 0.79-0.97] vs OR 0.84 [95%CI, 0.57-1.24]). On the other hand, the efficacy of EPA administered alone seems to be greater in terms of risk reduction of MI (OR 0.70 [95%CI, 0.61-0.80] vs OR 0.83 [95%CI, 0.66-1.06] with EPA+DHA administration).

Conclusions: The pharmacological approach with n-3 PUFA significantly improves cardiovascular outcomes. The efficacy of n-3 PUFA administration appears to relate to the type of active components, dosage and patients' CV risk.

4055 | Venous thromboembolism and risk of cancer in users of statins: A Danish population-based cohort study

Nils Skajaa, David Nagy, Frederikke Schønfeldt Troelsen, Dóra Körmendiné Farkas and Henrik Toft Sørensen

Aarhus University, Aarhus N, Denmark

Background: Venous thromboembolism (VTE) may be the first symptom of cancer. Statins are suggested to prevent VTE, but the risk of cancer in VTE patients using statins remains poorly understood.

Objectives: To examine the risk of cancer among VTE patients using statins.

Methods: We performed a nationwide, population-based cohort study based on prospectively recorded data in Danish health and administrative registries. The study period was 2006-2017. We identified first-time hospital-diagnosed VTE patients with a dispensed prescription for any statin within 90 days preceding the VTE diagnosis. We classified patients as current users if they initiated statin therapy before the preceding year of the VTE diagnosis and as new users if they initiated statin therapy within one preceding the diagnosis. We followed statin users from the date of VTE diagnosis to that of an incident cancer diagnosis, death, migration, or 31 December 2017, whichever occurred first. We computed absolute cancer risks, with death as a competing cause, and age-, sex-, and calendar-period standardized incidence ratios (SIRs), comparing the observed cancer incidence with the expected based on national cancer statistics.

Results: Among 8,286 (88%) current users of statin and 1,136 (12%) new users, we observed 1,230 and 183 cancer diagnoses during a median follow-up of 2.4 years (interquartile range: 0.7-5.1 years) and 3.6 years (interquartile range: 1.1-7.0 years), respectively. The one-year risk for any cancer was 7.0% (95% confidence interval [CI]: 6.5-7.6) for current users and 6.6% (95% CI: 5.3-8.2) for new users. The one-year SIRs for any cancers were 3.1 (95% CI: 2.9-3.4) for current users and 3.5 (95% CI: 2.8-4.4) for new users; the SIRs decreased to 1.2 (95% CI: 1.1-1.3) and 1.1 (95% CI: 0.9-1.4) in the following years of follow-up.

Conclusions: The risk of cancer was elevated approximately three-fold during the first year following a VTE diagnosis among patients using statins.

4117 | Coprevalence of comorbidities in medicare older adults with chronic obstructive pulmonary disease

Tham T. Le and Linda Simoni-Wastila

University of Maryland, Baltimore, MD

Background: Comorbidities increase with age and in the presence of chronic conditions, such as chronic obstructive pulmonary disease (COPD). The presence of multiple comorbid conditions (MCCs) pose challenges for COPD management and can lead to poor outcomes.

Objectives: To quantify the coprevalence of MCCs in Medicare older adults with COPD.

Methods: Design: A retrospective cohort study using a 5% Medicare beneficiary sample between 1/1/2012 and 12/31/2015. **Settings:** We included beneficiaries aged ≥65 years who were diagnosed with COPD by or before 12/31/2014. **Main outcomes:** Coprevalence of 40 comorbidities were identified using the Medicare Chronic Conditions files. **Statistical analyses:** Coprevalence was estimated as percentage of MCCs ever diagnosed at the end of the

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

study (12/31/2015) using all eligible beneficiaries as the denominator.

Results: Of 461,268 eligible beneficiaries, 60% were female, 86% were white, with mean (standard deviation [SD]) age of 79 (8) years. Among these, 89.2% had at least five and 50.4% had at least ten MCCs. Most prevalent comorbidities included hypertension (92.6%), hyperlipidemia (86.4%), anemia (74.9%), rheumatoid arthritis (RA) (68.0%), congestive heart failure (CHF) (49.6%), diabetes (46.7%), depression (43.7%), peripheral vascular disease (PVD) (42.9%), chronic kidney disease (CKD) (38.6%), asthma (38.3%), hypothyroid (36.3%), and pain (34.4%). Top co-prevalence of two conditions included hypertension-hyperlipidemia (82.4%), hypertension-anemia (71.7%), and hyperlipidemia-anemia (66.9%). The most common co-prevalence of three comorbidities were hypertension-hyperlipidemia-anemia (65.0%), hypertension-hyperlipidemia-RA (59.1%), and hypertension-anemia-RA (54.1%). Coprevalence of three, four, and five comorbidities were most likely between conditions such as hypertension, hyperlipidemia, anemia, arthritis, diabetes, CHF, PVD, and CKD.

Conclusions: Older COPD patients encounter a high burden of MCCs. The high coprevalence of chronic conditions underlines drug-drug interaction risks and the necessity of integrated care to improve health outcomes in patients with COPD.

4453 | History of lipid lowering therapy use among adults initiating treatment with proprotein convertase subtilisin/kexin type 9 antibody inhibitors in the United States, 2015-2019

Sara N. Levintow[1,2], Catie Wiener[1], Kate K. Orroth[3], Karminder Gill[3], Andrew Mullard[3], M. Alan Brookhart[1,4] and Leah J McGrath[1]
[1]*NoviSci, Durham, NC;* [2]*University of North Carolina, Chapel Hill, NC;* [3]*Amgen Inc., Thousand Oaks, CA;* [4]*Duke University, Durham, NC*

Background: Proprotein convertase subtilisin/kexin type 9 antibody inhibitors (PCSK9i) are novel treatments for patients with atherosclerotic cardiovascular disease and are effective at further reducing low-density lipoprotein cholesterol when combined with other lipid-lowering therapies (LLT). Cholesterol treatment guidelines discuss adding PCSK9i once maximally tolerated statin therapy has been reached, and documented statin therapy is a prior authorization criterion for many health plans in the US. Little is known about real-world treatment patterns of other LLT use among patients initiating a PCSK9i.

Objectives: To characterize the one-year history of other LLT use among PCSK9i initiators using Sankey visualizations.

Methods: We used the MarketScan Commercial and Medicare Supplemental claims to identify adults initiating a PCSK9i from August 2015 to March 2019. Patients were required to have 12 months of continuous enrollment in a healthcare plan before PCSK9i initiation. We used fill dates and days' supply from the pharmacy claims to capture LLT use in the one year preceding PCSK9i initiation. Treatment was assumed to occur from the fill date to 30 days after the end of the days' supply. We estimated the cross-sectional prevalence of LLT use (statin, ezetimibe, or none) on the initiation date and at 3, 6, 9, and 12 months before the initiation date.

Results: Among 11,958 adults initiating a PCSK9i, 6,221 (52%) had no other LLT use at the time of PCSK9i initiation. In the 6 months prior to PCSK9i initiation, 34% of all patients had no LLT use, and for the full 12 months before initiation, 26% had no LLT use. Patients who were female, older (>65 years), and initiated PCSK9i in earlier years (2015-2017) had a lower prevalence of prior use of other LLT. Among the 5,737 patients who were receiving other LLT at PCSK9i initiation, 44% were on a high-intensity statin (with or without ezetimibe). Other specific drug combinations included statin and ezetimibe combination therapy (27%), high-intensity statins without ezetimibe (26%), and ezetimibe alone (24%).

Conclusions: Despite treatment guidelines and prior authorization requirements for PCSK9i use as an adjunct to other LLT, many patients had no statin or ezetimibe use in the year before PCSK9i initiation. Future research is warranted on the real-world effectiveness of PCSK9i for patients with and without other LLT use.

4472 | Real world treatment patterns following the initiation of proprotein convertase subtilisin/kexin type 9 antibody inhibitors among adults in the United States, 2015-2019

Catie Wiener[1], Sara N. Levintow[1,2], Kate K. Orroth[3], Karminder Gill[3], Andrew Mullard[3], Leah J. McGrath[1] and M. Alan Brookhart[1,4]
[1]*NoviSci, Durham, NC;* [2]*University of North Carolina, Chapel Hill, NC;* [3]*Amgen Inc., Thousand Oaks, CA;* [4]*Duke University, Durham, NC*

Background: Clinical trials have demonstrated the efficacy and safety of proprotein convertase subtilisin/kexin type 9 antibody inhibitors (PCSK9i) for decreasing low-density lipoprotein cholesterol and reducing the risk of major cardiovascular events. However, there is limited real-world evidence on patterns of PCSK9i use. Specifically, treatment persistence and concurrent use of other LLT (statins and ezetimibe) are not well understood in patients initiating PCSK9i therapy.

Objectives: We used Sankey visualizations to depict treatment patterns of PCSK9i and other LLT use in the one year following PCSK9i initiation.

Methods: We used the MarketScan Commercial and Medicare Supplemental claims to identify adults initiating a PCSK9i from August 2015 to March 2019. Patients were eligible if they had 12 months of continuous enrollment prior to PCSK9i initiation and at least 3 months of follow-up data. We used fill dates and days' supply from the pharmacy claims to capture patterns of use for PCSK9i, statins, and ezetimibe after PCSK9i initiation. Treatment use was assumed to occur from the fill date to 30 days after the end of the days' supply. We assessed the cross-sectional prevalence of PCSK9i and other LLT treatments (statin, ezetimibe, or none) at 3, 6, 9, and 12 months following PCSK9i initiation. Inverse probability weights were used to address potentially informative censoring due to disenrollment and end of data over follow-up.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 11,958 adults initiating a PCSK9i, 88% were on a PCSK9i at 3 months, decreasing to 79% at 6 months, 74% at 9 months, and 70% at 12 months following initiation. PCSK9i use at 12 months was more common among males (73% vs. 66% for females), and slightly increased over time (67% for patients initiating in 2015 vs. 71% for 2018), but did not vary by age group (<65 years, ≥65 years). At PCSK9i initiation, 48% of patients had concurrent use of statins or ezetimibe. This percentage decreased over follow-up to 38% at 3 months, 34% at 6 months, 31% at 9 months, and 30% at 12 months. Further, 18% of patients were on no LLT at 12 months following initiation.

Conclusions: Using real-world data, we found that persistence with PCSK9i therapy remained relatively high at one year following treatment initiation. Although PCSK9i therapy is recommended as an adjunct to maximally tolerated statin therapy, fewer than half of PCSK9i initiators had concurrent use of statins or ezetimibe. Future studies could expand follow-up beyond one year to capture longer-term treatment patterns and clinical outcomes.

4581 | The prevalence and determinants of over- and undertreating hypertension and cholesterol levels in the Rhineland study

Nersi Alaeddin[1], Folgerdiena M. de Vries[1], Gökhan Pehlivan[1] and Monique M.B. Breteler[1,2]

[1]*German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany;* [2]*Institute for Medical Biometry, Informatics and Epidemiology (IMBIE), Bonn, Germany*

Background: Elevated blood pressure and cholesterol levels are major risk factors for cardiovascular disease (CVD). Although emphasis on control of these risk factors has increased, they often remain uncontrolled. Increased emphasis could also cause overtreatment, however evidence here is scarce.

Objectives: We aim to assess the prevalence and determinants of over- and undertreatment of hypertension and cholesterol levels in the general German population.

Methods: We used data from the Rhineland Study, a population-based cohort in Bonn, Germany, including people aged ≥30 years. Information on medical history and medication use were collected interview-based. We determined the prevalence of overtreatment (antihypertensive treatment and systolic blood pressure (SBP) <120 mmHg) and undertreatment (SBP ≥140 and/or diastolic blood pressure ≥90 mmHg) of hypertension and quantified determinants for this by using multinomial logistic regression (controlled hypertension as reference). Subsequently, we determined the prevalence of undertreating dyslipidemia (following ESC/ EAS guidelines) in the population aged 40-65 years and quantified determinants for this by using a binomial logistic regression model. We adjusted for age, sex, CVD, chronic kidney disease (CKD), diabetes, Body Mass Index, educational level and income in all models.

Results: Analyses were based on 3,875 out of 4,000 participants. Within the sample of participants with hypertension (n=1,483, mean age 63.8 years, standard deviation (SD) 12.4; 56% women), 12.9% (n=181) were over- and 54% (n=802) were undertreated. With increasing age the odds of overtreatment decreased (OR 0.97 95% confidence interval (95%CI) 0.96-0.98). Higher odds of overtreatment were observed in women compared to men (OR 0.43 95%CI 0.29-0.65) and in individuals with CKD compared to individuals without CKD (OR 2.14, 95%CI 1.25-3.65). Lower odds of undertreatment were observed for individuals with CVD (OR 0.53, 95%CI 0.38-0.74) and diabetes (OR 0.58, 95%CI 0.38-0.87) compared to individuals without the disease. Within the sample of participants with dyslipidemia (n=716, mean age 53.0 years, SD 7.0; 57% women)86.9% (n=622) were undertreated. With increasing age, the odds of undertreatment increased (OR 1.12 95%CI 1.07-1.18). Lower odds of undertreatment were observed in individuals with diabetes (OR 0.14 95%CI 0.07-0.29) and CVD (OR 0.10 95%CI 0.06-0.19) compared to individuals without the disease.

Conclusions: The high prevalence of undertreatment shows a need of optimizing medication use. However, we should be aware of the risk of overtreatment.

4726 | Beta-blockers and initial heart rhythm in out-of-hospital cardiac arrest: A multi-country case-control study

Talip Eroglu[1], Carlo Barcella[2], Michiel Hulleman[1], Asger Granfeldt[3], Patrick Souverein[4], Grimur Mohr[2], Rudolph Koster[1], Mads Wissenberg[2], Anthonius de Boer[4], Christian Torp-Pederson[5], Fredrik Folke[2], Marieke Blom[1], Gunnar Gislason[2] and Hanno Tan[1]

[1]*Amsterdam Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands;* [2]*Herlev and Gentofte Hospital, University of Copenhagen, Gentofte, Copenhagen, Denmark;* [3]*Aarhus University Hospital, Aarhus, Denmark;* [4]*Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands;* [5]*Aalborg University Hospital, Aalborg, Denmark*

Background: Out-of-hospital cardiac arrest (OHCA) is a leading cause of death in Western societies. Survival from OHCA with a non-shockable rhythm (NSR) [asystole, pulseless electrical activity] as initial heart rhythm is very low (2-3%), while survival from OHCA with a shockable rhythm (SR) [ventricular tachycardia/ventricular fibrillation] has increased to approximately 30%. Prior studies examining the association between beta-blockers and NSR reported conflicting results.

Objectives: To evaluate whether use of beta-blockers is associated with NSR as initial rhythm in OHCA.

Methods: We conducted two case-control studies using data from Emergency Medical Services attended OHCA-registries in Denmark and the Netherlands. Cases were patients with NSR following OHCA and controls were patients with SR following OHCA. Beta-blocker use was defined as a prescription 90 days prior to OHCA (the Netherlands) or when the prescription's theoretical end date occurred later than the OHCA-data (Denmark), and was further defined as use of either non-selective beta-blockers, β1-selective beta-blockers or α-β-dual-receptor blockers within 90 days prior to OHCA.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Multivariable logistic regression analyses were used to calculate odds ratios (ORs) and 95% confidence intervals (95% CI) to estimate associations between beta-blockers and NSR compared to no use of any beta-blockers. As covariates we included age, sex, resuscitation factors, cardiovascular disease and diabetes mellitus.

Results: We identified 15 997 cases and 7367 controls in Denmark, and 764 cases and 820 controls in the Netherlands. Compared to no beta-blocker, use of non-selective beta-blockers (Denmark: cases: 2.3%, controls: 1.1%; the Netherlands: cases: 3.8%, controls: 1.7%) was associated with a higher probability of NSR (Denmark: OR 1.86, 95%-CI 1.42-2.44; the Netherlands: OR 2.52, 95% CI 1.15-5.49), whereas use of β1-selective blockers (Denmark: cases: 22.7%, controls: 23.4%; the Netherlands: cases: 27.4%, controls: 28.1%) was not associated with NSR (Denmark: OR 1.04, 95%-CI 0.95-1.13; the Netherlands: OR 0.99, 95% CI 0.74-1.31). Use of α-β-dual-receptor blockers (Denmark: cases: 4.6%, controls: 5.2%; the Netherlands: cases: 2.9%, controls: 1.8%) was significantly associated with NSR in Denmark (OR 1.21; 95% CI 1.03-1.42) and not significantly in the Netherlands (OR 1.37; 95% CI 0.61-3.07).

Conclusions: Non-selective beta-blockers, but not β1-selective beta-blockers, are associated with NSR in OHCA. Further research is needed to explore the role of underlying morbidity on development of (non)shockable rhythms.

4767 | Metabolic surgery and cardiovascular benefits: The consequence of information bias in a real-world evidence study

William Murk[1], Jeremy Rassen[2] and Sebastian Schneeweiss[3]

[1]*Jacobs School of Medicine, University at Buffalo, Buffalo, NY;* [2]*Aetion, Inc, New York, NY;* [3]*Harvard Medical School, Boston, NY*

Background: Aminian et al. recently reported an analysis of electronic health records (EHRs) showing that metabolic surgery is associated with a 39% reduction in the risk of major adverse cardiovascular events (MACE) compared with non-surgery, among obese patients with diabetes (JAMA 2019).

Objectives: We hypothesized that this previous finding is spurious due to differential information bias, since non-surgical controls do not undergo the same pre-diagnostic workup as patients undergoing surgery. To evaluate this, we replicated the original study and then modified its design so that the comparison groups had similar levels of baseline information. This was done by choosing a control group that consisted of patients undergoing an unrelated surgery (total hip/knee replacement) and using high-dimensional propensity score (HDPS) to match patients.

Methods: We conducted a cohort study using the Optum® de-identified Electronic Health Record dataset, an aggregation of inpatient and ambulatory records from 81 million patients between January 2007 through March 2018. Diabetes patients were selected as previously described. We performed an analysis that replicated the original study design, where metabolic surgery patients were compared against risk-set sampled non-surgery controls and matched by propensity score. We then conducted a subsequent analysis where the control group was changed to patients undergoing total hip/knee replacement and a high-dimensional propensity score (HDPS) model was used to match patients. The matched groups included 338 metabolic surgery and 547 hip/knee replacement surgery patients. Outcomes included 6-component MACE (mortality, coronary artery disease, cerebrovascular disease, heart failure, atrial fibrillation, or nephropathy).

Results: The results of Aminian et al. were replicated using the same analytical design (HR [95% CI] for MACE: 0.61 [0.55, 0.69] in the original study vs. 0.67 [0.61, 0.73] in the present study). When the comparison group was changed to patients undergoing hip/knee replacement and HDPS was used, there was no protective effect of metabolic surgery (HR [95% CI]: 0.99 [0.76, 1.30]).

Conclusions: We demonstrated that information bias is the most likely explanation for the substantial cardiovascular benefit reported in the earlier study. Limitations in the present study include a small sample size in the matched comparison groups. Our findings highlight the importance of symmetric comparison groups when working with healthcare data without randomization.

4786 | Epidemiology and treatment of atrial fibrillation in patients with type 2 diabetes mellitus 2001-2016: An electronic database study in the United Kingdom

Hassan Alwafi[1], Ian Wong[1,2], Amitava Banerjee[3,4], Pajaree Mongkhon[5,6], Cate Whittlesea[1], Abdallah Y. Naser[7], Wallis Lau[1,2] and Li Wei[1]

[1]*Research Department of Practice and Policy, School of Pharmacy, University College London, London, United Kingdom;* [2]*Centre for Safe Medication Practice and Research, Department of Pharmacology and Pharmacy, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong;* [3]*Institute of Health Informatics, University College London, London, United Kingdom;* [4]*School of Health Sciences, University of Central Lancashire, Preston, United Kingdom;* [5]*Division of Pharmacy Practice, Department of Pharmaceutical Care, School of Pharmaceutical Sciences, University of Phayao, Phayao, Thailand;* [6]*Pharmacoepidemiology and Statistics Research Center (PESRC), Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand;* [7]*Faculty of Pharmacy, Al-Isra University, Amman, Jordan*

Background: Diabetes and cardiovascular diseases are often coexistent, and patients with Type 2 diabetes mellitus (T2DM) have an increased risk of Atrial fibrillation (AF). Previous studies that examined the incidence, prevalence and treatment of AF among patients with T2DM are limited.

Objectives: To investigate the prevalence, incidence and treatment of atrial fibrillation (AF) in type 2 diabetes mellitus (T2DM), assess the impact of direct oral anticoagulants (DOACs) introduction on oral anticoagulant (OACs) prescribing rates, and investigate factors associated with warfarin versus DOACs initiation in patients with T2DM and AF.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: The Health Improvement Network (THIN) database (2001-2016), was used to examine the annual prevalence, incidence and treatment of AF in T2DM. The impact of DOACs introduction on OAC prescribing rates were investigated using interrupted time series analysis (ITS). Factors associated with warfarin versus DOACs initiations were also identified using multivariable logistic regression. All analyses were performed using SAS version 9.4 (SAS Institute, Cary, NC, USA).

Results: The prevalence of AF increased from 2.7 (95% confidence intervals (CI) 2.5 - 2.8) in 2001 to 5.0 (4.9 - 5.1) in 2016 per 100 persons, whereas the incidence decreased over the study period from 1.0 (0.9 - 1.1) to 0.7 (0.7 - 0.8) per 100 persons. OACs prescribing within 30-days of AF diagnosis increased from 21.5% in 2001 to 56.8% in 2016. ITS analysis showed that OAC prescribing increased after DOAC introduction (P<0.001), however, no immediate change was observed (P=0.23). Older age (≥75 years old), history of bleeding and chronic kidney disease were strongly associated with DOAC prescriptions.

Conclusions: This study highlighted that there was an increase in prevalence of AF in patients with T2DM during the study period, particularly in both older patients and males. Further studies are warranted to investigate factors contributing to the underuse of OAC in patients with T2DM and AF.

4872 | Characteristics of patients newly diagnosed with atrial fibrillation after ischemic stroke hospitalization

Lu Zhang, Anna Watzker, Tiffany S. Woodworth, Mark Friedman and Joseph Menzin
Boston Health Economics, Boston, MA

Background: Studies suggests up to a quarter of ischemic stroke patients may be subsequently diagnosed with incident atrial fibrillation (AF), which may have been an undiagnosed and treatable risk factor for preventing ischemic strokes. There is limited real world evidence describing these patients.

Objectives: To evaluate the characteristics of patients with ischemic stroke and newly diagnosed AF.

Methods: We identified hospitalized Medicare-enrolled patients aged ≥66 years with primary ischemic stroke diagnosis code from January 1, 2010 to December 31, 2015, in a 5% sample of Medicare claims. Patients had no evidence of commercial enrollment, stroke, or AF in the 365 days prior to hospitalization. We assessed incidence of post-stroke AF diagnoses during a fixed 90-day follow-up window. Patients who died or were disenrolled during this window were excluded. We assessed demographic and clinical characteristics, including Quan Charlson Index (QCI), $CHADS_2$, and CHA_2DS_2-VASc score in the 365-day baseline period, among those with and without post-stroke AF. Statistical significance was tested using T-test and Pearson's chi-squared test.

Results: Among 24,237 patients hospitalized with incident ischemic stroke, 4,583 (18.9%) were newly diagnosed with AF within 90 days. Patients with post-stroke AF diagnoses were older (79.58 vs. 77.77 years, p<0.01) and more likely to be Caucasian (87.89 vs. 83.44%, p<0.01), but exhibited minor differences in comorbidity indices when compared to patients without post-stroke AF diagnoses (QCI: 1.41 vs 1.47, p=0.04; $CHADS_2$: 2.21 vs 2.17, p=0.06; CHA_2DS_2-VASc: 4.05 vs 4.03, p=0.42). However, AF and non-AF patients exhibited differential comorbid conditions included in the scores. In addition to being older, AF patients were more likely to have prevalent congestive heart failure (CHF) (15.95 vs. 12.19%, p<0.01), while non-AF patients were more likely to have prevalent diabetes (33.17 vs. 37.38%, p<0.01).

Conclusions: Consistent with previous studies, our data may indicate nearly one-fifth of stroke patients presented with undiagnosed AF. Based on common risk scores for stroke, patients newly diagnosed with AF after stroke were largely similar to patients that did not have AF. However, comorbid CHF and advanced age appeared to be the most significant differentiating factors between patients with and without post-stroke AF diagnoses. More research is needed to identify candidate predictors for AF, with focus on related factors of CHF, as targeted screening for AF may improve patient outcomes for ischemic stroke.

Disease Epidemiology/Clinical Course -> Diabetes

2533 | Differential risk of Parkinsons disease according to diabetes treatments: A cohort study

Ruth Brauer, Li Wei, Tiantian Ma, Dilan Athauda, Christine Girges, Nirosen Vijiaratnam, Grace Auld, Cate Whittlesea, Ian Wong and Thomas Foltynie
University College London, London, United Kingdom

Background: The elevated risk of Parkinson's Disease (PD) in patients with diabetes might be mitigated depending on the type of drugs prescribed to treat diabetes. Population data for risk of PD in users of the newer types of drugs used in diabetes, ie exenatide, are scarce.

Objectives: To compare the risk of PD in patients with diabetes exposed to thiazolidinediones (glitazones), glucagon-like peptide (GLP)-1 receptor agonists and dipeptidyl peptidase (DPP)-4 inhibitors, with the risk of PD of users of any other oral glucose lowering drugs.

Methods: We conducted a population-based cohort study using primary care data by The Health Improvement Network (THIN). Patients with a diagnosis of diabetes and at least two prescriptions for drugs used in diabetes between January 2006 and January 2019, were included in our study. The index date for each patient was the first prescribing date that qualified them for study entry. The primary outcome was the first recording of a diagnosis of PD after the index date, as identified from clinical records. We compared the risk of PD in individuals treated with glitazones (GTZ) or DPP-4 inhibitors and/or GLP-1 receptor agonists to people treated with other antidiabetic agents using a Cox regression with inverse probability of treatment weighting based on propensity scores. Multiple imputation was used for missing smoking status(1%), alcohol use(2%), BMI(4%) and HbA1c level(3%) prior to the index date.

Results: Among 100,288 patients (mean age 62.8 years [SD 12.6]), 329 (0.3%) were diagnosed with PD during the median follow-up of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

3.33 years. The incidence of PD was 8 per 10,000 person years (PY) in 21,175 patients using GTZ, 5 per 10,000 PY in 36,897 patients using DPP-4 inhibitors and 4 per 10,000 PY in 10,684 using GLP-1 mimetics, 6,861 of whom were prescribed GTZ and/or DPP-4 inhibitors prior to using GLP-1 mimetics. Compared with the incidence of PD in the comparison group (10 per 10,000 PY), adjusted results showed no evidence of an association between the use of GTZ and PD in the primary analysis (IRR 1.17; 95% CI 0.76-1.63), but there was strong evidence of an inverse association between use of DPP-4 inhibitors and GLP-1 mimetics and the onset of PD (IRR 0.64; 95% CI 0.43-0.88 and IRR 0.38; 95% CI 0.17-0.60, respectively).

Conclusions: The incidence of PD in patients diagnosed with diabetes varies depending on the treatment for diabetes received. The incidence of PD is nearly two times lower in users of DPP-4 inhibitors and/or GLP-1 receptor agonists compared to users of other oral antidiabetic drugs. Our study provides unique evidence to support further investigation of GTZ, DPP-4 inhibitor and GLP-1 mimetic use in PD.

2546 | Dental resource service utilization among type 2 diabetes patients: A real-world analysis using a linked claims and dental database

Ellen R. Thiel, Kristin Evans, Christopher Gregory and Debra E. Irwin
IBM Watson Health, Cambridge, MA

Background: Type 2 diabetes mellitus (T2DM) is associated with higher risk of dental disease. Differences in dental services utilization between T2DM patients and healthy controls using real world data is underreported in the literature.

Objectives: The aim was to use linked dental and administrative insurance claims to compare dental resource utilization among T2DM patients vs. controls without T2DM.

Methods: A retrospective, case-control design was used to analyze patient dental and medical claims from the IBM® MarketScan® Dental Database linked to the MarketScan Commercial and Medicare Supplemental Databases. The case cohort included adult patients with at least 2 medical claims with diagnoses for T2DM and no claims for type 1 diabetes. The control cohort included adult patients without diabetes diagnoses who were randomly selected from patients enrolled in MarketScan in 2016. During 2015 and 2016, cases and controls were required to be continuously enrolled with medical benefits, and during 2016 both cohorts were continuously enrolled in dental benefits and had at least 1 dental service. Data from 2015 were used to identify baseline demographic and clinical characteristics of the cohorts. Multivariate logistic regression modeling was used to control for differences in baseline characteristics and to evaluate the odds of experiencing at least one dental procedure of a specific type, comparing cases and controls.

Results: The analysis included 140,858 T2DM patients, and 236,811 non-T2DM control patients. Besides diagnostic and preventive visits, the most common dental procedures were restorative services (T2DM 43%; controls 39%), periodontics (T2DM 19%; controls 13%), oral/maxillofacial surgery (T2DM 12%; controls 7%), endodontics (T2DM 7%; controls 6%), and prosthodontics (T2DM 5%; controls 2%). T2DM patients were more likely to have endodontics (OR=1.17; CI 1.14-1.21); periodontics (OR=1.40; CI 1.37-1.43); oral/maxillofacial surgery (OR 1.56; CI 1.52-1.6); prosthodontics (OR 1.80; CI 1.73-1.87); restorative services (OR 1.04; CI 1.03-1.06) compared to controls.

Conclusions: This study provides real-world evidence of the association between T2DM and increased likelihood of dental disease. Future research into the specific T2DM oral health risks may provide valuable insights for prevention strategies.

2678 | Individualized glycemic control in type 2 diabetes in the US and Europe

Dominik Lautsch[1], Euan McLeod[2], Tongtong Wang[1], Swapnil Rajpathak[1], Claudio Gonzalez[1], Seema Malkani[1], Gary Milligan[3], James Jackson[3] and Victoria Higgins[3]
[1]Merck & Co., Inc, Kenilworth, NJ; [2]Pfizer Inc, Tadworth, United Kingdom; [3]Adelphi Real World, Bollington, United Kingdom

Background: Clinical guidelines in type 2 diabetes recommend individualization of glycemic goals, however clinical databases and real-world studies typically do not capture this measure.

Objectives: We used the 2018 Adelphi T2DM Disease Specific Programme (where individualized HbA1c goals are available) to understand the relationship between individual glycaemic goals, factors associated with goal attainment and treatment modification.

Methods: The 2018 Adelphi T2DM Disease Specific Program included a survey involving 730 physicians and 8794 patients in US and 4 European countries (Germany, Italy, Spain, and United Kingdom). Data on age, sex, body mass index (BMI), HbA1c, comorbid medical conditions and prescriptions were collected. Antihyperglycemic treatment regimens included were Metformin, Sulfonylureas (SUs), Thiazolidinediones (TZDs), dipeptidyl peptidase-4 inhibitors (DDP4i), glucagon-like peptide-1 receptor agonist (GLP-1RA), sodium-glucose cotransporter-2 inhibitors (SGLT2i), insulin plus any combination of the above. Patients had been prescribed current antihyperglycemic therapy $\geq$3 months were included in the analysis. Physician-reported target HbA1c values for individual patients were used to assess mean individual HbA1c goal.

Results: Our results suggested that the most recent mean HbA1c was 7.3%, mean individual HbA1c goal was 6.8% [Standard Deviation (SD) =0.69] with 38% patients having achieved their individualized goal. Patients achieving their individual HbA1c goal were older (62 vs 59 years), had lower BMI (29.5 vs 30.3), slightly lower diabetes duration (6.4 vs 6.8 years) or more likely to have chronic kidney disease (8.3% vs 7.5%). Mean HbA1c at diagnosis of type 2 diabetes was 8.4% (SD=1.8). Switch from one line of therapy typically occurred at higher mean HbA1c levels >8%. More specifically, the mean HbA1c in 2,348 patients who switched from 1st line of therapy was 8.3% (SD=1.4%). The mean HbA1c in 624 patients who switched from 2nd line of therapy was 8.4%

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(SD=1.3%). The mean HbA1c in 126 patients who switched from 3rd line of therapy was 8.5% (SD=1.6%). The mean HbA1c in 17 patients who switched from 4th line of therapy was 9.3% (SD=1.8%).

Conclusions: The mean individualized HbA1c goal was 6.8% and was attained by 38% of the patients. Switch from one line of therapy typically occurred at higher mean HbA1c levels >8%.

3694 | Metabolic factors and lifestyle habits associated with prevalence of polyneuropathy in early type 2 diabetes: A cross-sectional study of 5,249 patients in the Danish DD2 cohort

Diana H. Christensen[1,2], Søren T. Knudsen[3], Sandra S. Gylfadottir[2,4,5], Lotte B. Christensen[1], Jens S. Nielsen[6], Henning Beck-Nielsen[6], Henrik T. Sørensen[1], Henning Andersen[2,4], Brian C. Callaghan[2,7], Eva L. Feldman[2,7], Nanna B. Finnerup[2,4,5], Troels S. Jensen[2,4,5] and Reimar W. Thomsen[1]

[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus N, Denmark; [2]International Diabetic Neuropathy Consortium, Aarhus University, Aarhus N, Denmark; [3]Steno Diabetes Center Aarhus (SDCA), Aarhus University Hospital, Aarhus N, Denmark; [4]Department of Neurology, Aarhus University Hospital, Aarhus N, Denmark; [5]Danish Pain Research Center, Aarhus University, Aarhus N, Denmark; [6]Danish Center for Strategic Research in Type 2 Diabetes (DD2), Odense University Hospital, Odense, Denmark; [7]University of Michigan, Ann Arbor, MI

Background: Diabetic polyneuropathy (DPN) has a lifetime prevalence of up to 50% in type 2 diabetes, and many patients experience pain. The effectiveness of neuropathic pain medications is limited, and prevention of DPN and neuropathic pain is therefore crucial. High body mass index increases risk of DPN, whereas knowledge on other metabolic and lifestyle risk factors is sparse and conflicting.

Objectives: To examine the association of central obesity, other metabolic factors, and lifestyle habits with DPN and neuropathic pain in patients with early type 2 diabetes.

Methods: We characterized 6,726 patients with recently diagnosed diabetes enrolled into the Danish Centre for Strategic Research in Type 2 Diabetes (DD2) cohort according to metabolic factors and lifestyle habits using both primary collected data and register data. After a median of 2.8 years, we sent a detailed questionnaire on neuropathy, including the Michigan Neuropathy Screening Instrument questionnaire (MNSIq) to identify possible DPN (score ≥4) and the Douleur Neuropathique en 4 Questions (DN4) questionnaire for associated possible neuropathic pain (MNSIq ≥4 + pain in both feet + DN4-score ≥3). We used log-binomial and Poisson regression analyses to calculate age, sex, and diabetes duration-adjusted prevalence ratios (aPRs) of DPN and of painful DPN associated with the risk factors of interest.

Results: Among 5,249 patients with data on both DPN and pain, 17.9% (n=938) had DPN, including 7.4% (n=386) with neuropathic pain. Central obesity (waist circumference, waist-hip ratio, and waist-height ratio) was markedly associated with DPN. Other important metabolic factors associated with DPN included hypertriglyceridemia ≥1.7 mmol/L: aPR 1.36 (1.17; 1.59), decreased HDL cholesterol <1.0/1.2 mmol/L (male/female): aPR 1.35 (1.12; 1.62), high-sensitive CRP ≥3.0 mg/L: aPR 1.66 (1.42; 1.94), C-peptide ≥1,550 pmol/L: aPR 1.72 (1.43; 2.07), HbA1c ≥78 mmol/mol: aPR 1.42 (1.06; 1.88), and antihypertensive drug use: aPR 1.34 (1.16; 1.55). Smoking: aPR 1.50 (1.24; 1.81) and lack of physical activity (0 vs ≥3 days/week): aPR 1.61 (1.39; 1.85) were also associated with DPN. Among patients with DPN, smoking, high alcohol intake, and failure to increase physical activity after diabetes diagnosis associated with neuropathic pain.

Conclusions: We found strong evidence that metabolic syndrome factors, insulin resistance, and inflammation are associated with DPN in type 2 diabetes. Unhealthy, modifiable lifestyle habits associate with both DPN and neuropathic pain.

3706 | Polyneuropathy in early type 2 diabetes is associated with higher risk of subsequent cardiovascular disease: Evidence from the Danish centre for strategic research in type 2 diabetes (DD2) cohort

Sia Kromann Nicolaisen[1], Lasse Bjerg[2,3], Diana Hedevang Christensen[1], Reimar Wernich Thomsen[1], Jens Steen Nielsen[4,5], Signe Toft Andersen[2,6], Henning Beck-Nielsen[4,5], Troels Staehelin Jensen[6,7], Annelli Sandbæk[2,3], Daniel Witte[2,3] and Morten Charles[3,8]

[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Public Health, Aarhus University, Aarhus, Denmark; [3]Steno Diabetes Center Aarhus, Aarhus, Denmark; [4]DD2, Steno Diabetes Center Odense, Odense, Denmark; [5]Research Unit of Steno Diabetes Center Odense, University of Southern Denmark, Odense, Denmark; [6]Danish Pain Research Center, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [7]Department of Neurology, Aarhus University Hospital, Aarhus, Denmark; [8]Research Unit of General Practice, Aarhus University, Aarhus, Denmark

Background: Diabetic polyneuropathy (DPN) may be associated with subsequent risk of cardiovascular disease (CVD) and mortality in patients with early type 2 diabetes (T2D), but evidence is sparse.

Objectives: We used follow-up data in the DD2 research database to compare the risks of CVD and mortality among T2D patients with and without DPN.

Methods: Patients were assessed for DPN by a neuropathy questionnaire survey conducted in 2016 in the DD2 cohort of recently diagnosed T2D patients and linked to Danish prospective national healthcare registries. A score ≥4 on the Michigan Neuropathy Screening Instrument questionnaire (MNSIq) indicated DPN. We defined CVD as hospitalization with ischemic heart disease, stroke, peripheral artery disease, or heart failure. We followed the patients from the time of the neuropathy questionnaire survey and calculated adjusted incidence rate ratios (IRRs) of CVD and mortality using Poisson regression with adjustment for age, sex, HbA1c, BMI, smoking, alcohol consumption, LDL-cholesterol, systolic blood pressure, antihypertensive and lipid lowering medication, diabetes duration, albumin-creatinine-ratio, and prior cardiovascular event.

Results: A total of 5,028 T2D patients were included in the study. Median diabetes duration at the time of the questionnaire was 4.6 (IQR

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

3.5-5.7) years. In total, 818 (16.3%) patients had DPN. Patients with DPN were slightly younger than those without DPN (median 62.3 [IQR 54.8-70.1] vs. 65.7 [IQR 57.2-71.2] years) and a larger proportion were women (47.2 vs. 41.1%). Among patients with DPN, 30.3% had a prior cardiovascular event versus 19.7% of patient without DPN. Use of cardiovascular drugs was higher for antihypertensive drugs (75.8 vs. 72.7%) and aspirin (26.0 vs 21.9%) among patients with DPN, but lower for lipid-lowering drugs (70.8 vs. 72.3%). During a median of 2.2 (IQR 2.2-2.2) years of follow-up, 10.8% of the patients were diagnosed with CVD and 5.0% died. After adjustment, the risk of CVD was 57% (IRR 1.57 [95% CI 1.27-1.94]) and mortality was 20% (IRR 1.20 [95% CI 0.76-1.89]) higher in individuals with DPN compared to those without. Sensitivity analyses among patients without a history of CVD and complete case analyses showed similar results.

Conclusions: We found that DPN defined by MNSIq ≥4 associates with significantly higher risk of CVD after adjustment for well-known CVD risk factors. Notably, these associations were found in patients with early T2D emphasizing the importance of screening for this neglected diabetic complication.

3725 | Sex differences in the risk of diabetes mellitus among individuals with psoriasis

Raymond Milan[1], Jacques LeLorier[2], Ivan Litvinov[1], Kaberi Dasgupta[1] and Elham Rahme[1]

[1]McGill University, Montreal, QC, Canada; [2]Université de Montréal, Montreal, QC, Canada

Background: The choice of therapy for managing psoriasis varies according to its severity. It is also well established that psoriasis severity is associated with diabetes mellitus (DM) and severe psoriasis is more common in male than female individuals. However, sex differences in the risk of DM among individuals with psoriasis has not been examined.

Objectives: We assessed the risk of DM by psoriasis severity and identified predictors in male and in female individuals with psoriasis.

Methods: We conducted a retrospective cohort study using Quebec health administrative databases (1997 - 2015). Individuals ages ≥20 years were included if they received a first psoriasis diagnosis in 2000 - 2012 (Index date, ID), and either a second diagnosis or ≥1 claim for psoriasis treatment anytime afterward (N=27,582). Those who received a psoriasis treatment in the prior year, and those with a DM diagnosis in the prior or following year were excluded (to consider delays in DM diagnosis). Psoriasis treatments served as surrogates for disease severity: untreated, mild (topical agents), moderate (phototherapy), severe [conventional systemic agents (CSA) and biologic agents]. This definition was used as a time-varying exposure. DM was defined as 2 outpatient visits within 2 years or 1 hospitalization with a principal or secondary diagnosis for DM. Time-dependent multivariate Cox regression models (with 12-month lag) were used. Analyses were stratified by sex. Sensitivity analyses were conducted using other definitions for DM, different lag periods, and censoring individuals receiving methotrexate and cyclosporine because of their possible association with DM.

Results: This study included 11,236 individuals with psoriasis (52.4% females). DM incidence was higher in males (20/1000 person-years vs 17/1000 person-years for females). DM risk increased with psoriasis severity in both sexes (severe vs untreated individuals: hazard ratio; 95% CI: males 2.16, 1.44-3.25; and females 2.27, 1.42-3.63). The effect of age on DM differed between sexes and psoriatic arthritis was associated with DM only in male individuals (1.57, 1.10-2.24). Results were robust in most sensitivity analyses, except for censoring both CSA in which severe psoriasis was not associated with DM in both sexes.

Conclusions: Psoriasis severity, defined by the treatment received, is associated with DM in both males and females. Screening for DM should be considered for both sexes with high psoriasis severity and for male individuals with psoriatic arthritis.

3729 | Using Rwd to assess changes in GFR among DKD patients and the rate of heart failure

Seth Kuranz and Christian Haudenschild

TriNetX, Inc, Cambridge, MA

Background: Electronic medical records (EMRs) are a rich source of clinical data for the examination of disease progression in diabetic kidney disease (DKD) patients. EMR networks do not always have a clear source population or definition of time at risk.

Objectives: The objectives of this analysis were to examine glomerular filtration rate (GFR) as a predictor of heart failure (HF) among DKD patients, and to assess the impact of varying person time (PT) definitions.

Methods: The study was conducted using a US-based federated EMR network of 38M patients. DKD was defined as type 2 diabetes patients aged 20+ with an incident CKD diagnosis between 2015-2019 (index event (IE)). Patients were excluded if they had a kidney transplant, end stage renal disease, heart failure, or were deceased prior to or in the first year after the IE. Of those patients at risk for the outcome (n=76,240), 30,704 patients had at least one MDRD defined GFR measure in the year before and after the IE. Patients with increasing or decreasing GFR was further stratified by healthy (GFR ≥ 60 units) and unhealthy (15 ≤ GFR < 60 units) kidney function and categorized as follows: no change healthy (reference); no change unhealthy; increase from unhealthy to healthy; increase and remain unhealthy; decrease from healthy to unhealthy; decrease and remain unhealthy. The outcome was defined as the first HF diagnosis at least 1 year following the IE. Crude rate ratios (RRs) and differences (RDs) and 95% CIs were calculated. A Poisson regression model was used to calculate RRs adjusting for baseline confounders. The analyses were repeated with three varied definitions of PT, which involved adding 30-, 183-, and 365-day windows before and after each visit in the EMR during follow up. All patient characteristics were defined by ICD, LOINC, CPT, or RxNorm terminology.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Patients were 48% female with a mean age between 65 (12) and 71 (10) at the IE. In the unadjusted analyses, assuming a 30-day PT window, patients whose GFR decreased from healthy to unhealthy or decreased and remained unhealthy had 1.6 (1.2-2.2) and 1.5 (1.1-2.0) times the rate of HF. Accompanying RDs found 4.7 and 3.7 more cases of HF per 100,000 person days. Adjusted models [RR:1.4 (1.0-1.8); RR:1.1 (0.8-1.5), respectively] and increases in the PT window consistently attenuated results.

Conclusions: Patients whose GFR decreased from healthy to unhealthy levels experienced the highest rate of HF with PT definitions strongly influencing the results. Researchers should clearly communicate assumptions around PT definitions and further analyses should continue to explore necessary assumptions when using EMR networks.

3962 | Statin therapy and risk of polyneuropathy in type 2 diabetes: A population-based cohort study

Frederik Pagh Kristensen[1,2], Diana Hedevang Christensen[1,2], Brian Callaghan[2,3], Søren Tang Knudsen[4], Søren H. Sindrup[2,5], Eva L. Feldman[2,3], Leif Østergaard[2,4], Henning Andersen[2,6], Troels Staehelin Jensen[2,6], Henrik Toft Sørensen[1] and Reimar Wernich Thomsen[1]

[1]Institute of Clinical Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]International Diabetic Neuropathy Consortium, Department of Clinical Medicine, Faculty of Health, Aarhus University, Aarhus, Denmark; [3]University of Michigan, Ann Arbor, MI; [4]Aarhus University Hospital, Aarhus, Denmark; [5]Odense University Hospital, Odense, Denmark; [6]Institute of Clinical Medicine, Aarhus University Hospital, Aarhus, Denmark

Background: 50% of all diabetes patients may experience diabetic polyneuropathy (DPN) during their life with diabetes. Statin therapy may prevent DPN through lipid-lowering and anti-inflammatory effects, or increase DPN risk through neurotoxic effects.

Objectives: To investigate the impact of statin therapy on risk of development of DPN.

Methods: We conducted a 15-year, population-based cohort study by linking medical health databases to include all Danish, first-time diabetes patients <30 years from 2002-2016. First diabetes record was defined as either a first-time hospital contact for diabetes or a first-time glucose-lowering drug prescription. New statin users filled their first statin prescription between 180 days before and 180 days after their first diabetes record. Prevalent statin users filled statin prescriptions both during and before this period. DPN was defined by a validated algorithm based on ICD-10 hospital diagnosis codes (positive predictive value = 74%). We followed patients from 180 days after first diabetes record (index date) until first-time DPN, death, emigration, or study end. We used Cox proportional hazard regression analysis to compute hazard ratios (aHRs) controlling for confounding factors.

Results: The type 2 diabetes study population consisted of 59,255 (22.8%) new statin users, 75,528 (29.0%) prevalent users, and 124,842 (48.1%) statin non-users. Patients were followed for a median of 6.7 years (IQR 3.4-9.6 years). Incidence rates of DPN per 1000 person-years were similar in new users (4.0 events), prevalent users (3.7 events) and statin non-users (3.8 events). The aHR for DPN was 1.05 (95% CI, 0.98-1.11) in new users, and 0.97 (95% CI, 0.91-1.04) in prevalent users, as compared with statin non-users. There was an increased DPN risk in new statin users during the first year (aHR 1.30 (95% CI, 1.12-1.53)) that disappeared after ≥2 years of follow-up, suggesting either detection bias or an early detrimental effect of statins. For new statin users, the overall null-association persisted in propensity score matched analyses (HR 1.02 (95% CI, 0.93-1.12)) and in a subgroup of patients after additional adjustment for baseline blood lipids (aHR 1.04 (95% CI, 0.92-1.19)). Additional on-treatment analyses showed a slightly increased DPN risk in new statin users (aHR 1.17 (1.09-1.27)), however, this was mainly restricted to the first year (aHR 1.42 (95% CI, 1.21-1.68)).

Conclusions: Statin therapy was not associated with reduced or increased risk of subsequent DPN in type 2 diabetes.

3979 | Daily lifestyle behaviors associated with initiating of renal replacement therapy in Japanese patients with chronic kidney disease: A descriptive study using a claims database linked with specific health checkup results

Kazuaki Enomoto[1], Azusa Hara[1], Nanae Tanemura[1], Takumi Hirata[2], Tomonori Okamura[1] and Hisashi Urushihara[1]

[1]Keio University, Tokyo, Japan; [2]Hokkaido University Faculty of Medicine, Sapporo, Japan

Background: A chronic kidney disease (CKD) eventually progresses to end-stage renal disease, requiring dialysis or kidney transplantation. It is important to explore the prognostic factors associated with the progression of CKD to prevent initiation of renal replacement therapy.

Objectives: We investigated the effects of the daily lifestyle behaviors on the initiation of renal replacement therapy among CKD patients using an employment-based large-scale claims database linked with specific health checkups (SHC) data.

Methods: This retrospective study included 149,620 CKD patients aged 40-74 years who took SHC between April 2008 and March 2016 from the Japanese claims database. CKD patients were identified using ICD-10 codes and/or according to the following information obtained from the SHC data; eGFR less than 60 ml/min per 1.73 m^2 or the presence of positive proteinuria in a urine sample. We investigated the 11-item daily lifestyle behaviors recorded in the questionnaire survey at annual SHC, including current smoking, regular exercise, regular walking, walking speed, frequent breakfast-skipping, eating speed, eating dinner late, frequent snacking, alcohol drinking frequency, alcohol consumption, and sleep quality. Initiation of renal replacement therapy was defined by medical procedure claims. Cox proportional hazards regression model with recency-weighted cumulative exposure as a time-dependent covariate was employed to identify daily lifestyle behaviors related to the initiation of renal replacement therapy.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: During 384,042 patient-years of follow-up by the end of March 2016, 295 dialysis and no kidney transplantation cases were identified. In time-dependent Cox regression models, frequent breakfast-skipping (hazard ratio [HR]: 9.28, 95% confidence interval [CI]: 2.81, 30.61), frequent snaking (HR: 7.20, 95%CI: 1.96, 26.43), drinking sake three glasses and more per day compared with those less than 1 glass of sake (HR: 14.04, 95%CI: 1.41, 139.62), and sleep quality (HR: 2.72, 95%CI: 1.09, 6.77) were associated with initiating renal replacement therapy.

Conclusions: Among CKD patients, daily lifestyles of skipping breakfast, snaking, heavy drinking, and sufficient sleep were independent predictors for initiating renal replacement therapy. Our study suggests that improving such daily lifestyles might delay the progression of CKD to prevent initiation of renal replacement therapy in the Japanese working generation.

4150 | Age- and sex-specific incidence of non-traumatic lower limb amputation in patients with type 2 diabetes mellitus in a claims database from the United States

Sampada Gandhi, Chuntao Wu, Maximiliano Waschbusch, Madlen Michael, Meng Zhang, Xinyu Li and Juhaeri Juhaeri
Sanofi, Bridgewater, NJ

Background: There is limited data on age- and sex-specific incidence rates (IR) of lower limb amputation (LLA) in patients with type 2 diabetes mellitus (T2DM). These data can be used to support the understanding of this risk associated with the use of newer antidiabetic agents (ADA).

Objectives: To estimate age- and sex-specific IRs of LLA in T2DM patients using a U.S. claims database for years 2007 to 2018.

Methods: Using a retrospective cohort study design, patients with T2DM who were 18 years and older and met one of the following criteria were identified during a study period from January 1, 2007 to September 30, 2018 from the Truven MarketScan database: (1) at least 2 diagnoses of T2DM and <=1 diagnosis of T1DM defined using ICD-9 or ICD-10 diagnosis codes, or (2) at least 1 diagnosis of T2DM, at least 1 claim for oral or injectable ADA, and <=1 diagnosis of T1DM. The index date for a patient was defined as the date of first diagnosis code of T2DM or date of first dispensing of ADA, whichever occurred first. All events of non-traumatic LLA occurring from the index date until the end of the study period were identified by the presence of ICD-9 or ICD-10 procedure codes. Patients were followed until the end of the study period or enrollment in the database, whichever occurred first. An overall and age- and sex-specific IRs per 1,000 person-years (PY) of LLA and their 95% confidence intervals (CIs) were calculated.

Results: Of the 6,117,981 T2DM patients identified during the study period, 52.0% were males, and 58.7% of the patients were in the age ranges of 50-69 years, with 14.0% 70 years and older. Of the 14,627 LLA events, 72.8% were minor LLA (at or below the ankle) and 27.2% were major LLA (above ankle). The overall IR (95% CI) of LLA, minor LLA, and major LLA per 1,000 PY were 0.86 (0.85, 0.88), 0.63 (0.62, 0.64), and 0.23 (0.23, 0.24), respectively. When stratified by sex, males had a higher IR compared to females regardless of the type of LLA [Overall: 1.24 (1.22, 1.26) Vs. 0.46 (0.45, 0.48); Minor: 0.92 (0.90, 0.94) Vs. 0.32 (0.31, 0.33); Major: 0.32 (0.31, 0.33) Vs. 0.14 (0.14, 0.15)]. When stratified by age and sex, an increase in overall LLA incidence was observed in both males and females with an increasing age, with the highest incidence reported in patients aged ≥80 years [Males: 1.91 (1.77, 2.05); Females: 1.02 (0.93, 1.11)]. A similar pattern was observed for both minor and major LLA.

Conclusions: In patients with T2DM, the majority of the non-traumatic LLA events were minor. The incidence rate of LLA increased with an increasing age and was higher among males compared to females.

4228 | Cardiorenal disease is the most common first cardiovascular manifestation in type 2 diabetes and associated with increased mortality

Jetty A. Overbeek[1], Esmé Lighaam[2], Gerard C.M. Linssen[3], Ron M.C. Herings[1,4] and Johan Bodegård[5]
[1]PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands; [2]AstraZeneca, The Hague, Netherlands; [3]Hospital Group Twente, Almelo and Hengelo, Netherlands; [4]VU University Medical Center, Amsterdam, Netherlands; [5]AstraZeneca, Oslo, Norway

Background: Cardiorenal disease, defined by heart failure (HF) or chronic kidney disease (CKD), is a serious cardiovascular disease (CVD) complication among patients with type 2 diabetes (T2D). Several recent trials in T2D have shown significant reduced risk of cardiorenal disease during treatment with a sodium-glucose cotransporter-2 (SGLT-2) inhibitor. However, data on cardiorenal disease among T2D patients without established CVD is scarce.

Objectives: To determine the cardiorenal disease manifestation and, second, its associated mortality risks in T2D patients without CVD and renal disease, referred to as CVD-free patients.

Methods: In this observational study, all prevalent patients aged ≥18 years with at least two blood glucose lowering drug prescriptions prior to index date (i.e. 1st January 2012) were included and those with less than 12 months of medical history, T1D or gestational diabetes were excluded. In the Dutch PHARMO Database Network, patients without diagnoses of CVD or renal disease were defined as CVD-free. Firstly, CVD manifestation was determined by the first event of stroke, myocardial infarction (MI), peripheral artery disease (PAD) and cardiorenal disease. Secondly, we compared patients with a single diagnosis of HF, CKD, MI, stroke or PAD with CVD-free patients. Age and sex adjusted Cox regressions were used for risk estimations.

Results: Of 46,451 T2D patients; 36,903 (79%) were identified as CVD-free at index date and followed for a mean period of 4.6 years. Of the 4,498 (12.2%) T2D patients who developed a CVD during follow-up, cardiorenal disease was most common (57%; 23% HF and 35% CKD), followed by MI (17%), PAD (13%) and stroke (12%).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Compared with the CVD-free group, HF was associated with increased risk of CKD (HR 1.60 [95%CI: 1.06-2.42]), and CKD was numerically associated with increased risk of HF (HR 1.28 [95%CI: 0.74-2.22]). Cardiorenal disease, HF, CKD and HF+CKD were associated with increased risk of all-cause mortality, HR 2.48 (95%CI: 2.17-2.83), HR 2.73 (95%CI: 2.29-3.25), HR 2.18 (95%CI: 1.77-2.67), HR 4.08 (95%CI: 2.57-6.49), respectively, compared to CVD-free T2D.

Conclusions: In T2D patients without a history of cardiovascular or renal disease, cardiorenal disease was the most common first CVD manifestation and was associated with significantly increased risk of all-cause mortality. Cardiorenal disease is an important early complication in T2D that should be considered when choosing optimal preventive strategies.

4272 | The pharmo diabetes, management, and treatment (DIAMANT) cohort: A population-based cohort of people with type 2 diabetes

Jetty A. Overbeek[1], Louise Lemmens[1], Amber A.W.A. van der Heijen[2], Giel Nijpels[2] and Ron M.C. Herings[1,2]

[1]*PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands;* [2]*VU University Medical Center, Amsterdam, Netherlands*

Background: Despite better awareness and new developments in treatment of diabetes and prevention of type 2 diabetes (T2D), the number of persons with diabetes continues to rise. This increasing prevalence and the still unclear long-term safety and effectiveness of new and old blood glucose lowering treatments, stresses the need for more pharmacoepidemiological studies. A prospective, regularly updated cohort of people with T2D would provide quick and up to date-information regarding prevalence, treatment, long-term safety and effectiveness.

Objectives: To study the cohort profile of the PHARMO Diabetes, MANagement and Treatment (DIAMANT) cohort.

Methods: All people with T2D in the PHARMO Database Network are selected from the Out-patient Pharmacy (1998-2018) and the General Practitioner (GP) Database (2009-2018). T2D is defined as ≥2 dispensings/prescriptions for a non-insulin drug used to treat diabetes or a GP recorded diagnosis of T2D. The date of the second dispensing/prescription or the first GP recorded diagnosis, whichever occurred first, is defined as the index date. All patients are followed from index date until the end of the study period, data availability, or death, whichever occurred first. Patients are characterised in terms of demographics, medication use, comorbidities, and laboratory measurements.

Results: During 1998-2018, the DIAMANT cohort increased from 86,571 people in 1998 to 504,046 people in 2018. Overall, the mean (±SD) follow-up was 7.6 (± 5.0) years. In 2018 mean (±SD) age was 69 (±14) years and 48% was female. The most commonly used blood glucose lowering drug was metformin (58%), followed by sulfonylureas (27%) and insulin (19%). GLP-1 receptor agonists, DPP-4 and SGLT-2 inhibitors were used among 1.3%, 3.4% and 1.6% patients with T2D, respectively. The most common comorbidities reported were renal impairment and albuminuria/proteinurian The mean (±SD) BMI in 2018 was 29.7 (±5.3) kg/m^2 and 68% was current or former smoker. The mean (±SD) HbA1c in 2018 was 54 (± 12) mmol/mol. The mean (±SD) lipid values were 4.4 ± 1.0 mmol/l (total cholesterol), 2.4 ± 0.9 mmol/l (LDL), 1.21 ± 0.35 mmol/l (HDL), and 1.9 ± 1.2 mmol/l (triglycerides).

Conclusions: The PHARMO DIAMANT cohort provides the opportunity to gain real-world insights into the course of diabetes and treatment effects among people with T2D in daily practice. Furthermore, this cohort can be used for other unique purposes as well, such as linkage to other databases to study other questions and predictive analytics to support direct patient care.

4321 | Factors related to sodium glucose cotransporter 2 inhibitor (SGLT2i) and dipeptidyl peptidase 4 inhibitor (DPP4i) dispensing among naive, incident, and prevalent new users

Yandong Qiang[1], Casie H. Horgan[2], Andrew B. Petrone[2], Joy Kolonoski[2], Aaron Hansbury[2], Christian Hampp[1], Sarah Dutcher[1], Sruthi Adimadhyam[2] and Sengwee Toh[2]

[1]*Food and Drug Administration, Silver Spring, MD;* [2]*Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA*

Background: Observational studies with prevalent new users have been proposed to improve statistical power and generalizability. Failure to account for differences in characteristics among different types of new users may compromise internal validity.

Objectives: To identify factors related to SGLT2i dispensing among naïve, incident, and prevalent new users.

Methods: We identified type 2 diabetes patients in 8 Sentinel data partners with a dispensing of SGLT2i or DPP4i in 2013-2018. We classified patients as naïve users if they had no dispensing of any non-metformin (NM) antihyperglycemic agents (AHA) in the prior 365 days, incident new users if they had no baseline use of both SGLT2i and DPP4i, and prevalent new users if they were free of the cohort-defining drugs at baseline. We assessed factors related to the dispensing of SGLT2i over DPP4i among these types of users.

Results: During the study period, 93,369, 313,900, and 427,307 SGLT2i users were naïve, incident, and prevalent, respectively, as were 280,694, 723,705, and 758,232 DPP4i users, respectively. Among SGLT2i prevalent users, 27% had baseline DPP4i and 22% were naïve users. Among DPP4i prevalent users, 5% had baseline SGLT2i and 37% were naïve. On average, SGLT2i users were 6.9, 6.6. and 5.6 years younger than DPP4i users in the naïve, incident, and prevalent cohorts, respectively. The mean adapted Diabetes Complications Severity Index difference between SGLT2i and DPP4i users was 0.7 in the naïve users and 0.6 in both the incident and prevalent users. The imbalances in baseline covariates between SGLT2i and DPP4i weakened from naïve to incident and prevalent users. Compared to the DPP4i users, prevalent SGLT2i users were more likely to have prior use of thiazolidinedione (TZD, odds ratio [OR]=1.39; 95% confidence

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

interval=1.38-1.41), glucagon-like peptide 1 agonist (GLP1, OR=4.40; 4.34-4.46), short-acting (SI, OR=1.87; 1.85-1.90), and long-acting insulins (LI, OR=1.89; 1.88-1.91); while incident SGLT2i users were less likely to have prior use of sulfonylureas (OR=0.89; 0.88-0.90) but more likely to have prior TZD (OR=1.30; 1.28-1.32), GLP1 (OR=5.76; 5.68-5.85), SI (OR=2.23; 2.20-2.27), and LI (OR=2.16; 2.14- 2.18).

Conclusions: Baseline characteristic imbalances between SGLT2i and DPP4 initiators varied between naïve, incident, and prevalent new users. Prior NM AHA use played an important role in the choice of SGLT2i over DPP4i. Proper design and analytic approaches addressing these imbalances require consideration in epidemiologic studies including all new users.

4363 | The pattern of incident fractures in patients with newly diagnosed type 2 diabetes mellitus

Johanna H.M. Driessen[1], Cindy Sarodnik[2], Nicklas H. Rasmussen[3], Sandrine P.G. Bours[1], Nicolaas C. Schaper[1], Peter Vestergaard[3], Patrick C. Souverein[4], Morten Jensen[3], Frank de Vries[1] and Joop P.W. van den Bergh[5]

[1]Maastricht University Medical Centre, Maastricht, Netherlands; [2]Maastricht University, Maastricht, Netherlands; [3]Aalborg University Hospital, Aalborg, Denmark; [4]Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands; [5]Viecuri Medical Center, Venlo, Netherlands

Background: Fracture risk is associated with an increased risk of mortality and morbidity, e.g. hip fractures have been associated with an excess mortality risk of more than 30%. Patients with type 2 diabetes mellitus (T2DM) are at an increased risk of fracture. However, it is unclear whether fracture risk is already increased in patients with newly diagnosed T2DM, whether this risk differs across fracture locations and whether this is different for men and women.

Objectives: To study fracture risk according to location and sex in patients with newly diagnosed T2DM compared to matched controls.

Methods: A population-based retrospective cohort study using data from the UK Clinical Practice Research Datalink (CPRD) GOLD was conducted. All patients aged 30 year and older with a T2DM diagnose code and a first ever prescription of a non-insulin anti-diabetic drug (NIAD) between 1987 and 2017 were included. Each patient was matched by year of birth, sex and practice to one control. The date of the first NIAD prescription determined the index date and this date was also assigned to the matched control. Patients were followed from their index date up to the date of death, end of data collection, end of study period, or the date of the fracture of interest, whichever came first. Fractures were identified using Read codes and broken down by location. Fracture location and sex specific incidence rates (IRs) and incidence rate ratios (IRRs) were calculated using a Poisson model and Wald confidence limits.

Results: We included 124,328 patients with T2DM and 124,328 matched controls (44% women, mean age 63 years, mean follow-up 7.5 years). The overall fracture IR was lower in patients with newly diagnosed T2DM as compared to controls (IRR: 0.97; 95% confidence interval (CI): 0.94-0.99). The IR of a major osteoporotic (IRR: 0.93; 95%CI: 0.89-0.97), clavicle (IRR: 0.67; 95%CI: 0.56-0.80), radius/ulna (IRR: 0.81; 95%CI: 0.75-0.86) and vertebral (IRR: 0.83; 95%CI: 0.75-0.92) fracture was also lower in patients with T2DM as compared to controls. In contrast, the IR of an ankle (IRR: 1.16; 95%CI: 1.06-1.28), foot (IRR: 1.11; 95% CI: 1.01-1.22), humerus (IRR: 1.11; 95% CI: 1.03-1.20) and tibia/fibula (IRR: 1.17; 95% CI: 1.03-1.32) fracture was higher in patients with T2DM as compared to controls. Similar results were found in women. While in men only clavicle (lower) ankle and foot (both higher) fracture IRs were significantly different as compared to controls.

Conclusions: Fracture incidence rates differ per fracture location and by sex when comparing patients with T2DM to controls, with a higher incidence of fractures at the lower extremities and the humerus.

4391 | Ethnic differences in statin prescribing for people with type 2 diabetes

Sophie V. Eastwood[1], Rohini Mathur[2], Liam Smeeth[2], Krishnan Bhaskaran[2] and Nishi Chaturvedi[1]

[1]University College London, London, United Kingdom; [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: In the UK, people of South Asian and African Caribbean descent have higher rates of type 2 diabetes (T2DM) complications (e.g. cardiovascular disease [CVD]) than European-origin people. Poorer risk factor control may contribute. UK guidelines recommend statin treatment for primary prevention at ≥10% 10 year CVD risk in people with T2DM.

Objectives: To assess ethnic differences in statin prescribing in T2DM.

Methods: Primary care cross-sectional study using the Clinical Practice Research Datalink. Prevalent T2DM was algorithmically defined, high CVD risk designated by a 10 year risk score≥10% in the absence of prevalent CVD, and statin use (any timepoint) ascertained from medication records. Associations between ethnicity and statin use were studied using logistic regression models, firstly for all people with T2DM and secondly for those with high CVD risk. Models were adjusted for: age, gender, ever smoking, anti-hypertensive use and prevalent CVD (whole sample only). Analyses were stratified by gender, practice location and age group.

Results: A total of 152,499 (87%) European, 15,978 (9%) South Asian and 6,555 (4%) African Caribbean people with T2DM were identified. South Asians and African Caribbeans were younger than Europeans (median ages: 62, 61 and 71 yrs) and more likely to be in London, but less likely to have smoked, taken antihypertensives or have CVD. Rates of CVD risk score recording (38-40%) did not differ by ethnicity. Comparable proportions of South Asian and European people were prescribed statins (OR [95% CI] in an age- and gender-adjusted model: 0.99 [0.95,1.03], after further adjustment for smoking, antihypertensives and CVD: 1.14 [1.09,1.19]). Results were similar for the high

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

CVD risk group. However, marked differences in statin prescribing were seen between African Caribbean and European people, with the former group being about 40% less likely to receive a statin, regardless of CVD risk (African Caribbean vs. European ethnicity ORs in T2DM population: 0.57 [0.53,0.60] in an age- and gender-adjusted model and 0.60 [0.57,0.64] in the fuller model; ORs in the high CVD risk population: 0.60 [0.53,0.68] and 0.58 [0.51,0.66] respectively). Patterns were identical in all strata of age, gender and location.

Conclusions: African Caribbean people with T2DM are substantially less likely than their European counterparts to be prescribed statins, regardless of 10 year CVD risk. Statin prescribing did not differ between South Asians and Europeans. Further research should focus on explanations and informing policy to address ethnic differences in prescribing and ultimately diabetes outcomes.

4458 | Impact of policy changes on the delivery of community medication review services among adults with diabetes in Ontario

Ahmad Shakeri[1], John-Michael Gamble[2], Lori MacCallum[1], Lisa Dolovich[1], Nancy He[1] and Suzanne M. Cadarette[1]
[1]University of Toronto, Toronto, ON, Canada; [2]University of Waterloo, Kitchener, ON, Canada

Background: Adults with diabetes often take multiple medications to manage not only hyperglycemia, but also hypertension, hyperlipidemia and other comorbidities. The risk of drug therapy problems is therefore substantive and medication reviews are one method to optimize the safety and effectiveness of a patient's medication regimen. Since 2007, the Ontario government has funded pharmacy medication review services (MedsCheck Annual [MCA]) for residents taking 3+ drugs. In 2010, MedsCheck was broadened to include patients with diabetes (MCD). In an effort to standardize service delivery, a policy change was initiated in 2016 that added structured pharmacist documentation, including extra diabetes-specific education and goal-setting. In addition, pharmacists needed to provide evidence of diabetes educator training to provide MCD.

Objectives: To examine the impact of the policy change on the use of MedsCheck services among adults with diabetes.

Methods: We identified adults (19+ years) living in the community with diabetes in Ontario 12-months pre- and post-intervention (October 2016) using linked healthcare administrative data. Service uptake was calculated as the monthly rate of MedsCheck services per 10,000 adults with diabetes. Interrupted time series analysis (segmented linear regression with autoregressive error models) was used to identify the change in use after intervention (compared to predicted absent policy change), and the trend 12 months after; while accounting for seasonality, non-stationarity, and autocorrelation.

Results: 1,368,211 adults with diabetes received 705,578 MedsCheck services (34% of patients) over the study period. Service delivery was stable in the year prior to intervention with rate of 153 for MCD and 75 for MCA in September 2016. An immediate decline in use was observed (−81% MCD, −38% MCA) in October 2016. Thereafter, a significant increase in MCA services was seen that exceeded predicted values by September 2017 (+21%). In contrast, minimal change was seen for MCD and rates remained lower than predicted by September 2017 (−54% MCD). Overall (MCA or MCD), fewer patients accessed MedsCheck services following the policy change (-37%) by September 2017.

Conclusions: A decline in the rate of adults with diabetes receiving MedsCheck services was seen after a policy change that required more pharmacist training and additional documentation; with evidence of some displacement from MCD to MCA. Better understanding of the barriers that resulted in the shift from MCD to MCA and the decline overall will help inform future policy changes to improve access to MCD.

4757 | Assessing the impact of a non-alcoholic fatty liver disease (NAFLD) diagnosis on prescribing of GLP-1RA, DPP4i, and TZD medications

Danni Zhao, Matthew J. Alcusky and Anthony P. Nunes
University of Massachusetts Medical School, Worcester, MA

Background: No medications have been approved to treat non- alcoholic fatty liver disease (NAFLD) by the FDA. However, beneficial effects of select antidiabetic drugs (i.e., liraglutide, exenatide, and pioglitazone) on improving metabolic and histologic features of NAFLD have been demonstrated in randomized controlled trials. It is unknown whether diagnosis of NAFLD affects clinicians' preferential prescribing of antidiabetic drugs.

Objectives: To assess the timing of a NAFLD diagnosis relative to the initiation of glucagon- like peptide- 1 receptor agonists (GLP-1RAs), dipeptidyl peptidase- 4 inhibitors (DPP- 4is) and thiazolidinediones (TZDs).

Methods: We conducted a retrospective cohort study from 2012 to 2019 among adult patients with NAFLD who newly initiated GLP-1RAs (i.e., albiglutide, dulaglutide, exenatide, and liraglutide), DPP- 4is (i.e., alogliptin, linagliptin, saxagliptin, and sitagliptin), and TZDs (i.e., pioglitazone and rosiglitazone) using MarketScan® Explorys® Claims- EMR Data Set. The initiation date of an antidiabetic agent was used as the index date. We specified a 12- month baseline and follow up period before and after the index date, respectively, to ascertain the earliest date of a NAFLD diagnosis. Each patient can contribute multiple initiation episodes. We described the frequency distribution of NAFLD diagnoses relative to initiation of antidiabetic agents. Using principles of sequence symmetry analyses (SSA), we estimated the crude and adjusted sequence ratios and 95% confidence intervals from conditional logistic regression models, controlling for time- constant confounders and time trends that may artificially introduce an asymmetry.

Results: Overall, 4,640 patients initiated GLP- 1RAs (n = 2,243), DPP-4is (n = 2, 587), or TZDs (n = 350) over the study period. About 60% initiation episodes were subsequent to diagnosis of NAFLD. The crude sequence ratios were 1.63 (95% CI: 1.49- 1.77) for GLP- 1RA

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

initiators, 1.46 (95% CI: 1.35- 1.58) for DPP- 4i initiators, and 1.59 (1.28- 1.98) for TZD initiators. After controlling for time trends that may artificially introduce an asymmetry, patients who initiated GLP-1RAs, DPP- 4is and TZDs had sequence ratios of 1.39 (95% CI: 1.32-1.45), 1.29 (95% CI: 1.23- 1.34) and 1.42 (95% CI: 1.27- 1.59), respectively.

Conclusions: Patients were more likely to initiate GLP- 1RAs, DPP-4is, or TZDs following diagnosis of NAFLD over a 12- month period. The increased odds suggest that clinicians may shift their prescribing towards these clinically appropriate medications despite NAFLD not being a labeled indication.

4986 | Characterizing trajectories of HbA1c control and associations with vascular outcomes in adults with type 2 diabetes

Rohini Mathur[1], Christopher Rentsch[1], Sophie V. Eastwood[2], Nish Chaturvedi[2], Jessica Franklin[3], Niteesh Choudhry[3], Ian Douglas[1] and Liam Smeeth[1]

[1]*London School of Hygiene and Tropical Medicine, London, United Kingdom;* [2]*University College London, London, United Kingdom;* [3]*Brigham & Women's Hospital Department of Medicine, Boston, MA*

Background: In Type 2 diabetes (T2DM), intensive glycaemic control is key to reducing the risk of major vascular outcomes. Characterizing clinical features associated with good control is an important step towards characterizing populations in highest need of intervention.

Objectives: To identify and characterize clinically useful trajectories of HbA1c control in a UK cohort of newly diagnosed T2DM and determine associations with vascular outcomes.

Methods: An observational cohort study using the Clinical Practice Research Datalink was conducted using 234,191 adults aged 18 and over diagnosed with T2DM between 1988 and 2017 (mean follow-up 6.2 years). Annual mean HbA1c measures were derived by averaging all HbA1c values for each year of follow-up. Latent class growth curve modelling was used to identify groups based on the first five years of follow-up. The ideal number of trajectories was selected based on model fit criteria and clinical relevance. Multinomial logistic regression was used to identify demographic and baseline characteristics associated with trajectory membership. Amongst those free from prevalent vascular disease, multivariable cox-proportional hazards regression was used to compare risk of incident cardio- and micro-vascular disease between trajectory groups after the initial five-year trajectory definition period.

Results: Three clinically meaningful HbA1c trajectories were identified; 63.7% of the population were classified as having 'Optimal control; 29.2% were classed as having 'Adequate control', while 7.1% were classed as having 'Poor control'. Compared to those with optimal control, individuals with adequate or poor control were younger at diagnosis, more likely to be smokers, from more deprived areas, with higher HbA1c, BMI, and vascular co-morbidities at diagnosis. Risk of incident cardiovascular disease was 25% in the adequate control group relative to the optimal control group (95%CI 1.14-1.37) and 83% higher in the poor control group (95%CI 1.57-2.13). Risk of microvascular disease was similarly increased by 18% in the adequate control group (95%CI 1.12-1.24) and 69% in the poor control group (95%CI 1.55-1.84).

Conclusions: We characterized clinically useful differences between individuals belonging to three distinct classes of HbA1c control. Non-optimal glycaemic control was found to be strongly associated with increased risk of vascular outcomes. Further investigation of the relationship between glycaemic trajectories and treatment patterns will be key to developing strategies to target those with persistently poor control.

Disease Epidemiology/Clinical Course -> Neurological/Mental Health

2501 | Threatened abortion and risk of epilepsy, cerebral palsy and attention-deficit/hyperactivity disorder in offspring: A registry-based cohort study in Denmark

Elena Dudukina, Erzsébet Horváth-Puhó, Henrik Toft Sørensen and Vera Ehrenstein

Aarhus University, Aarhus, Denmark

Background: Children born following a pregnancy complicated by threatened abortion (TAB) are at increased risk of autism spectrum disorders. It is unknown whether TAB is associated with other neurologic and behavioral disorders.

Objectives: To examine incidence rate (IR), incidence rate difference (IRD), and hazard ratio (HR) of epilepsy, cerebral palsy, and attention-deficit/hyperactivity disorder (ADHD) in offspring born from a pregnancy affected with TAB as compared with offspring born from a pregnancy unaffected with TAB.

Methods: : In this cohort study, we included singletons live-born in Denmark, 1979-2010. The exposed cohort included children born from a TAB-affected pregnancy before 20th gestational week. The comparison cohort included children born in the same calendar period from a TAB-unaffected pregnancy. The three study outcomes were hospital diagnosis of epilepsy, cerebral palsy, and hospital ADHD diagnosis or use of ADHD drugs. We applied a sibling comparison design to estimate HRs of the outcomes in pairs of discordantly exposed full siblings born in 1991-2010. We followed the children from birth until the earliest of each of the outcomes, 16th birthday, emigration, death, or December 31, 2016. For each outcome, we computed crude IR and IRD (per 1000 person-years). Using Cox proportional hazards regression, we computed HRs with 95% confidence intervals (CIs) while adjusting for the calendar year, birth order, parental age, maternal pre-pregnancy somatic, psychiatric and neurologic morbidity, medication use, employment, education, and income.

Results: In the total population (N=1 864 221), 59 134 (3.2%) offspring were in TAB cohort and 1 805 087 offspring were in the comparison cohort. The population of full siblings included 20 091 discordantly exposed pairs. In the TAB cohort of the total population, the IRs of epilepsy, cerebral palsy, and ADHD were 1.6 (1.5-1.7), 0.4 (0.3-0.4), and 3.2 (3.0-3.4), respectively. The IRD with the comparison

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cohort was small (0.4 for epilepsy, 0.1 for cerebral palsy, and 0.8 for ADHD). In the total population, the offspring from TAB cohort was at 1.2-fold (1.2-1.3) increased hazard of epilepsy, at 1.4-fold (1.2-1.6) increased hazard of cerebral palsy, and at 1.2-fold (1.1-1.3) increased hazard of ADHD. In the sibling analyses, all associations were attenuated: HR=1.0 (0.9-1.2) for epilepsy, HR=1.2 (0.8-1.6) for cerebral palsy and HR=1.1 (0.9-1.2) for ADHD.

Conclusions: We found a weak association between TAB and offspring's subsequent risk of the neurological and behavioral outcomes of interest.

2525 | Associations of benzodiazepines, Z-drugs and other anxiolytics with subsequent dementia in patients with affective disorders: A nationwide cohort and nested case-control study

Merete Osler[1] and Martin B. Jørgensen[2]
[1]*Center for Clinical Research and Prevention, Bispebjerg and Frederiksberg Hospitals, Frederiksberg, Denmark;* [2]*Psychiatric Center Copenhagen Department O, Copenhagen, Denmark*

Background: Benzodiazepines and Z-drugs are of the most prescribed agents worldwide. Due to cognitive side effects the question of their influence on risk of dementia has been raised.

Objectives: To examine the associations of benzodiazepines, Z-drugs and other anxiolytics with incident dementia in patients with affective disorders.

Methods: We did a cohort and nested case-control study of 235,465 patients above 20 years with a first-time hospital contact for an affective disorder from 1996 through 2015 identified in the Danish National Patient Registry. From the Danish Prescription Registry we obtained information on all prescriptions for benzodiazepines, Z-drugs and other anxiolytics and followed patients for incident dementia (defined by hospital discharge diagnoses or acetylcholinesterase inhibitor use). Cox proportional hazard and conditional logistic regression were used to calculate hazard and odds ratios with adjustment for sociodemographic and clinical variables.

Results: A total of 75.9% n=171,287) of patients with affective disorders ever used BZD or Z-drugs and during the median follow-up of 6.1 year (IQR 2.7-11), 9,776 (4.2%) patients were diagnosed with dementia. Ever use of BZD or Z-drugs showed no association with subsequent dementia after multiple adjustments neither in the cohort or nested case-control design. In the cohort analyses number of prescriptions or cumulated dose of BZD or Z-drugs at baseline were not associated with dementia, while in the nested case-control study where prescriptions were counted from 1995 until 2 years before the index date, there was a slightly higher odds ratio for dementia in patients with lowest use of BZD or Z-drugs (odds ratio 1.08, 95%CI, 1.01-1.15) relative to never users. However, those with highest use had the lowest odds of dementia (odds ratio 0.83, 95%CI, 0.77- 0.88).

Conclusions: This large cohort study of patients with affective disorders did not show associations between use of BZD or Z-drugs and subsequent dementia even when exposures were cumulated or split into long and short-acting drugs. Some results were actually in favour of a protective effect.

2527 | Treatment patterns of patients with major depressive disorder and suicidal ideation or attempt

David M. Kern, M. Soledad Cepeda and Frank Wiegand
Janssen R&D, Titusville, NJ

Background: Patients diagnosed with major depressive disorder (MDD) and having suicidal ideation comprise approximately one-quarter of those with MDD, yet little is known about how they are treated.

Objectives: To understand the treatment patterns of medications and procedures for subjects with MDD and suicidal ideation (SI) or suicide attempts (MDD+SI/SA) 1 year following their first occurrence of SI/SA.

Methods: We identified patients diagnosed with MDD and a diagnosis for conditions related to SI/SA from a large US claims database of commercially insured individuals during 1/1/2014 to 6/30/2019. The index date was the first observed medical claim in the database for SI/SA. Patients were required to have continuous enrollment in the database ≥1 year prior to the index date, with no minimum follow-up required. Patients with evidence of autism, mania, psychosis or dementia any time prior to index were excluded. Treatment patterns included procedures for electroconvulsive therapy (ECT) and transcranial magnetic stimulation (TMS), and medications of selective serotonin reuptake inhibitors (SSRI), serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, monoamine oxidase inhibitors, other antidepressants (mainly bupropion and trazodone), anxiolytics, hypnotics/sedatives, lithium, psychostimulants, and atypical antipsychotics. Changes in class-based regimens were determined according to switching or adding of a new medication class to an existing regimen. Treatment patterns were captured up to 1 year following the index SI/SA.

Results: We identified 49,575 patients diagnosed with MDD+SI/SA. Patients were followed for 265 days on average, with 51% having a full year of observation. During this time, 75% received ≥1 treatment of interest. Of the treated, 57% received ≥2 distinct regimens, while 32% received ≥3 and 17% received 4 or more. Use of multiple therapy classes simultaneously was common, occurring in 62% of patients. There was heterogeneity in treatments received, with SSRI alone the most common first treatment (17%) followed by other antidepressants (10%), anxiolytics (9%), antipsychotics (7%) and anticonvulsants (6%). Use of ECT (0.9%) and TMS (0.3%) any time during follow-up was rare.

Conclusions: Of patients with MDD+SI/SA receiving pharmacotherapy or ECT/TMS, nearly two-thirds received multiple medication classes simultaneously at some point in the year following their first recorded SI/SA event. Use of medications other than antidepressants during this time was relatively common practice. Switching or adding-on classes was also frequent.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 2607 | Prevalence and incidence of narcolepsy in Japan: A study using Japanese claims data

Motonobu Sakaguchi[1], Motonobu Sakaguchi[1], Yumiko Ogino[1], Chao Chen[2] and Shreya Davé[2]
[1]*Takeda Pharmaceutical Company Limited, Osaka, Japan;* [2]*Takeda Pharmaceuticals International Co., Cambridge, MA*

Background: Previous studies suggest a relatively higher prevalence of narcolepsy in Japan than in Europe and North America, however these studies with Japanese data had some methodological limitations such as reliance on self-report questionnaires. More data is therefore, required to accurately estimate the epidemiology of narcolepsy in Japan.

Objectives: The objective of the study was to determine the prevalence and incidence of narcolepsy overall, and by age and gender, and estimate the numbers of total narcolepsy cases across Japan.

Methods: A retrospective cross-sectional study was conducted using the JMDC database. Patients who were continuously enrolled from January 2014 to December 2017 were eligible. Prevalence cohort was composed of the eligible population, and incident cohort was restricted to those without any narcolepsy diagnoses any time before 1st January 2017 from the eligible population. Considering the local practice in diagnosing narcolepsy, narcolepsy cases were identified by two definitions to obtain a range of prevalence and incidence rates within which the true rate was likely to lie. A) broad case definition (upper limit): patients having one diagnosis (ICD-10 code, G474) followed by a confirmed diagnosis; B) narrow case definition (lower limit): patients having at least one sleep test, including electroencephalogram, polysomnography, or multiple sleep latency test, and any subsequent confirmed diagnosis. Descriptive analyses were used to summarize the demographics for the patients with narcolepsy. All analyses were performed using SAS 9.4 (SAS Institute, Cary, NC).

Results: Among the prevalent cohort, 1,066 cases and 571 cases were fulfilled using the broad and narrow definition respectively. Among the incident cohort, 121 cases and 76 cases were met by the broad and narrow definition respectively. The age-sex adjusted prevalence of overall narcolepsy was 22.3-45.3 per 100,000 persons, projected to 28-57 thousand narcolepsy patients across Japan. The highest prevalence occurred among those 20-29 years of age. The age-sex adjusted incidence rate was 0.37-0.64 per 100,000 person-years, suggesting 500-800 newly diagnosed patients every year.

Conclusions: We concluded that the prevalence of overall narcolepsy is not as high as previously reported in Japan, but may still be higher than the prevalence in Western countries. In this study, it appears that the incidence rate was the highest in the second decade, fitting the natural history. The reason for the lower prevalence in the age 10-19 years needs to be further explored.

2671 | Increased risk of falls and fractures in patients with psychosis and Parkinson disease

Joan Forns[1], J. Bradley Layton[2], Jennifer Bartsch[2], Mary Ellen Turner[3], Colleen Dempsey[3], Mary Anthony[2], Mary E. Ritchey[2] and George Demos[3]
[1]*RTI-HS, Barcelona, Spain;* [2]*RTI-HS, Research Triangle Park, NC;* [3]*ACADIA Pharmaceuticals, San Diego, CA*

Background: Psychosis is a common complication of Parkinson disease (PD), particularly at advanced stages of the disease, with prevalence up to 75%. Both PD and PD with psychosis (PDP) have been implicated as risk factors for falls and fractures due to cognitive and motor impairment. Yet it has not been established whether the risk of falls and fractures is higher in patients with PDP compared with patients with PD.

Objectives: To evaluate whether the risk of falls and fractures differed in patients with PD or PDP at a similar disease stage.

Methods: This study was conducted using the MarketScan (IBM Watson Health) commercial and Medicare claims databases from 2008 to 2018. Patients with a PD diagnosis without psychosis were followed from the first identified PD diagnosis date during the study time period. After a noted psychosis diagnosis, patients were included in the PDP cohort. Patients with PD and patients with PDP were matched at similar points in their disease trajectories using a sequential propensity score matching approach. Falls and fractures were captured both as composite and separate outcomes. The incidence rates (IR), expressed per 100 person-years, and 95% confidence intervals (CI) of falls and fractures were estimated. Incidence rate ratios (IRRs) compared patients with PDP with patients with PD without psychosis in the matched samples.

Results: We identified 154,306 patients with PD without psychosis who did not have falls or fractures before the index date; the IR for falls and fractures was 11.41 events (95% CI, 11.29-11.53). Most of the events were falls. There were 12,127 (7.8%) patients with a subsequent diagnosis of PDP that met the inclusion/exclusion criteria. These patients with PDP had higher prevalences of most comorbidities and risk factors for falls and fractures than those without psychosis. The IR of falls and fractures among patients with PDP was 29.03 (95% CI, 28.27-29.81); falls were most commonly recorded. After matching, 24,144 (15.6%) patients with PD without psychosis and 12,077 (99.6%) with PDP were retained. Within the matched groups, patients with PDP had higher incidences of falls and fractures than those without psychosis (IRR = 1.44; 95% CI, 1.39-1.49). The increased rate was noted separately for falls (IRR = 1.48; 95% CI, 1.43-1.54) and any fractures (IRR = 1.17; 95% CI, 1.08-1.27) as well as within specific types of fracture, including pelvis and hip fractures.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: The present study suggests a modest but precise and consistent increased risk of falls and fractures in patients with PDP compared with patients with PD.

3775 | Excess deaths associated with treatment resistance in patients with major depressive disorder

Philip Brenner, Lena Brandt, Michel Nijs, Johan Reutfors and Therese Andersson
Karolinska Institutet, Stockholm, Sweden

Background: Patients with treatment resistant depression (TRD) have an increased mortality rate compared to other patients with depression, but it is not known how this translates into absolute numbers of excess deaths.
Objectives: To determine the number of excess deaths among patients with TRD compared to other depressed patients.
Methods: Nationwide Swedish governmental registers were used to identify a cohort of 118,774 antidepressant initiators 18-69 years old with a depression diagnosis. Patients with bipolar disorder, psychotic disorder and dementia were excluded. Patients who initiated a third consecutive, adequate treatment trial were classified as having TRD. An adequate trial was defined as lasting at least 30 days of antidepressant treatment or add-on treatment with antipsychotics, anticonvulsants or lithium, or a series of neurostimulation treatment. Flexible parametric survival models were used to estimate the rate of deaths due to all causes, as well as due to external causes (accidents or suicide) only, comparing TRD to patients with other depression. Analyses were adjusted for clinical and sociodemographic covariates, and included interactions with TRD, age, and major somatic comorbidities (expressed as Charlson Comorbidity Index, CCI). Standardized survival was estimated. Numbers of excess deaths within five years per 1000 patients with TRD were calculated and stratified by age and somatic comorbidity categories, and compared to if patients with TRD had had the same survival as the other patients with depression.
Results: A significant number of excess deaths were found among patients with TRD in all age and comorbidity categories, except for patients with CCI 2 or over, where numbers were too low for significance. The highest number of excess all-cause deaths per 1000 patients within 5 years was 16 (95% CI 5-28) among patients 18-29 years old with CCI 1. For deaths due to external causes, numbers of excess deaths were highest among patients 50-69 years old with 1 major somatic comorbidity (15 per 1000 patients; 95% CI 2-28).
Conclusions: A number of excess deaths due to both any cause of death and to external causes may be avoidable among patients with TRD had they similar survival rates as other patients with depression.

3779 | Incidence rates (IR) and IR ratios of Parkinson disease in patients with cataract compared to the general population: Analyses using the clinical practice research datalink (CPRD)

Claudia Becker[1,2], Laura Eggenschwiler[2], Susan S. Jick[3,4] and Christoph R. Meier[1,2,3]
[1]University of Basel, Basel, Switzerland; [2]University Hospital Basel, Basel, Switzerland; [3]Boston Collaborative Drug Surveillance Program, Lexington, MA; [4]Boston University, Boston, MA

Background: Previous research suggests a link between cataract and Parkinson disease (PD). This has been confirmed in one observational study (Lai et al 2015). If there was more evidence that cataracts may precede PD, cataract patients could be informed earlier about their future risk of PD.
Objectives: To analyse the incidence of PD in patients with or without cataract.
Methods: In the UK-based CPRD database, we identified incident PD patients in a cohort of patients with cataract, aged over 39 years, between 1995 and 2018, and a random sample of the general population matched for age, sex, GP and year of cataract. We assessed PD incidence rates (IRs) and incidence rate ratios (IRRs). We defined PD similar to previous studies by diagnosis code, 2 or more prescriptions (Rx) for anti-PD drugs and no Rx for drugs inducing parkinsonism within 180 days prior to the PD date. We excluded individuals with secondary PD or atypical parkinsonian disorders. Since we observed a large amount of patients with 2 or more Rx for anti-PD drugs but no PD diagnosis, we performed a sensitivity analysis, defining the outcome by 2 or more Rx for anti-PD drugs only (no PD diagnosis needed). In this analysis, we excluded patients with a disorder that could also be treated with anti-PD drugs (i.e., restless leg syndrome, acromegaly or hyperprolactinaemia). In a further sensitivity analysis we censored events occurring within one year after cohort entry to ignore PD cases diagnosed shortly after cataract occurrence. We assessed cases by age, sex, exposure, and year. We calculated person-time of exposure by adding up individual exposure times.
Results: In the main analysis, we included 152'500 patients with cataract and an equal amount of cataract free individuals. During follow-up, we identified 1'144 cataract patients with PD as well as 1'058 PD cases among controls. The crude IR of PD was 0.95 (95% CI 0.90-1.01) per 1'000 person-years (py) in patients with cataract and 0.94 (0.89-1.00) per 1'000 py in the comparisons. The IRR was 1.01 (0.93-1.10). The IRR was slightly increased in men (1.11, 0.99-1.24). The analysis based on drug Rx only included 50% more PD cases and also yielded an overall IRR around 1.00. The IRR for men was 1.19 (1.08-1.31). Results were similar in the analysis omitting the first year of follow-up.
Conclusions: In contrast to a previous study, we did not observe an increased risk of PD in patients with cataract compared to the general population overall. We plan to further study risk factors for PD on this association by means of a case-control study nested in our cataract cohort.

3806 | Caregiving burden, chronic pain and opioid utilization among parents of children with special healthcare needs

Wendy Camelo Castillo[1], Oluwadamilola Onasanya[1], Beth B. Hogans[2], Susan dosReis[1] and Gloria Reeves[1]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]University of Maryland Baltimore, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD

Background: Parents of children with special needs are at high risk for developing chronic non-cancer pain (CNCP). Yet, the impact of caregiving burden on the physical health of parents of children with special needs has seldom been studied.

Objectives: To estimate the prevalence of CNCP and opioid utilization, and examine the association of caregiving burden with CNCP among parents of children with special needs.

Methods: A cross-sectional analysis of a nationally representative survey of households participating in the 2015 Medical Expenditure Panel Survey identified households with at least one child under the age of 18. Caregiver burden was defined as having at least one child with a mental health diagnosis only, functional limitation only, both or none. Parental CNCP was defined as having a diagnosis of back, head, neck, arthritis or chronic pain. Opioid use was defined as reporting at least one prescription fill. We estimated the prevalence of CNCP and opioid use overall and for each of the four subgroups. Multivariable logistic regression was used to examine the association between caregiver burden and CNCP, adjusted for caregiver mental health and disability, socio-demographics and family structure (single or dual parenting). All estimates and 95% confidence intervals (CI) were weighted to represent the national census-based population.

Results: The 7,582 caregivers were female (59.1%) and on average aged 38.5 (SD 8.9) years. CNCP prevalence was highest in households with a child with both conditions (42.7% CI 32.7-52.8) and lowest among households where the child had neither (17.6% CI 15.9-19.3). Opioid prevalence was highest among caregivers of children who only had functional limitations (4.58% CI 1.56-7.61). Caregivers with a child with both conditions were 2.35 (CI 1.41-3.89) as likely to report chronic pain when compared to households were children had none. Parental disability, depression and age were associated with higher odds of chronic pain.

Conclusions: Caregivers of children with functional and mental health impairment are an at-risk population for chronic pain and opioid use, and for whom evidence for best practices is lacking.

3983 | A population-based cohort study of disruptive mood dysregulation disorder among youth in the US

Xiaofeng Zhou[1], Prethibha George[1], Rongjun Shen[1], Gong Richard[1], Robert L. Findling[2] and Phillip B. Chappell[3]
[1]Pfizer Inc., New York, NY; [2]Virginia Commonwealth University, Richmond, VA; [3]Pfizer Inc., Groton, CT

Background: Disruptive mood dysregulation disorder (DMDD) is a childhood-onset depressive disorder that is characterized by a persistent pattern of outbursts and severe irritability. DMDD was introduced as a new diagnosis in the 5th edition of the Diagnostic and Statistical Manual in 2013. Epidemiology data about DMDD in youth are limited.

Objectives: To estimate incidence rates (IRs) and prevalence of DMDD among youth in United State; and investigate patients' demographic characteristics, comorbidities including suicidal behavior, and concurrent medications.

Methods: A retrospective cohort study using 2016-2018 Optum EHR data was conducted. Children aged 10-<18 years with ≥183 days of enrollment prior to cohort entry date and met study inclusion/exclusion criteria were included. DMDD was defined by ICD 10-CM code F34.81. Annual incidence rates (IRs) per 1000 patient year (PY), prevalence (%), and 95% confidence intervals (CIs) were estimated. Proportions of 13 comorbid psychiatric conditions and concurrently prescribed psychiatric medications within 6 months prior to or after 1st incident DMDD were calculated.

Results: A total of 7,677 youth with DMDD during 2016-2018 were identified. With a mean age of 13 years, the cohort had more males (64%), whites (73%), and non-Hispanic (87%). Nearly a third of patients each had the following insurance coverage: commercial (28%), Medicaid (31%), and uninsured (27%). IRs per 1000 PY rapidly increased from 0.87 [95%CI: 0.84, 0.91] in 2016 to 1.75 [95% CI: 1.67, 1.82] in 2018. A similar pattern was found for the prevalence (%) increasing rapidly from 0.08% [95% CI: 0.08, 0.08] in 2016 to 0.35% [95% CI: 0.08, 0.08] in 2018. Most prevalent comorbidities in DMDD youth were attention deficit hyperactivity disorder (ADHD) (72%), other depressive disorders (70%), and anxiety disorders (50%), followed by oppositional defiant disorder (36%), conduct disorder (27%), and suicidal ideation (27%). Examining concurrent medication prescription revealed that DMDD youth received ADHD medication (60%), antipsychotics (59%), any antidepressants (54%), any mood stabilizers (24%), and anxiolytic agents (15%). Further, 69% of patients were prescribed 2 or more different medications.

Conclusions: To our knowledge, this is the first study reporting incidence, prevalence, comorbidity, and concurrent medication of DMDD in US youth using a large longitudinal EHR database. Our results add real-world evidence to the scarce literature on the epidemiology of DMDD. Future analyses may benefit from medical chart review to confirm outcomes, confounder adjustment, and estimation with other databases.

4018 | Association of renal and cognitive function in an elder population: analysis of NHANES 2011 and 2013

David Vizcaya[1], Peter Kolkhof[2] and Montse Soriano-Gabarro[3]
[1]Bayer, Barcelona, Spain; [2]Bayer, Wuppertal, Germany; [3]Bayer, Berlin, Germany

Background: Impaired renal function is a natural consequence of ageing and of certain diseases and is associated with vascular damage and inflammation, which in turn may cause loss of cognitive function

Objectives: To assess the association between estimated glomerular filtration rate (eGFR) and three cognitive test scores in a US elder population

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: People aged 60 years or more participating in the National Health and Nutrition Examination Study (NHANES) editions of 2011 and 2013 conformed the study base. Those with cognitive testing and with serum creatinine value available were included in the analysis. Renal function was calculated as estimated glomerular filtration rate (eGFR) in mL/min/1.73 m^2 using the CKD-EPI formula and subjects were classified according to 3 groups: >60, 30 to 60 and <30. Cognitive function was assessed with three tests: The Consortium to Establish a Registry for Alzheimer's disease (CERAD) Word Learning subtest, the Animal Fluency test (AFT) and the Digit Symbol Substitution (DSS) test. We used Poisson and linear regression models to estimate the association between renal (by 10 units increase of eGFR, or eGFR categories) and cognitive function (score of each test, separately). All models were adjusted for age, educational level attained, ethnicity, gender, history of stroke, marital status and NHANES edition

Results: A total of 3126 (15.7%) participants from both NHANES editions were included in the analysis. No substantial demographic and clinical differences were observed between both editions. Study participants were aged 70.1±7.0 years old and 45% were non-Hispanic whites. Close to 6% never lived with a partner and 47.2% of the population had at least some college education. Near to 15% of the participants had an eGFR < 60. The results of the cognitive tests were similar in 2011 and 2013 being the mean±SD scores 5.8±2.4, 45.5 ±17.4 and 80.3±18.7 for CERAD, AFT and DSS tests, respectively. The analysis showed no adjusted association between CERAD score and neither with eGFR or with eGFR categories. In contrast both AFT and DSS were associated with eGFR: regression coefficients and (95% confidence intervals) (RC): 0.14 (0.03; 0.25) for AFT and 0.48 (0.19; 0.78) for DSS. Likewise, eGFR grouping showed a consistent association: eGFR>60 vs 30 to 60 RC: -1.10 (-1.64; -0.55) for AFT and -1.89 (-3.39; -0.39) for DSS; eGFR>60 vs <30, RC: -1.98 (-3.30; -0.66) for AFT and -6.46 (-10.10; -2.82) for DSS

Conclusions: Recent NHANES data shows a consistent link between renal and cognitive function assessed with AFT or DSS tests in elder population from the US regardless of age and other confounders

4180 | Leveraging real world data to characterize rates of elevated liver enzyme levels among patients diagnosed with migraine

William K. Mountford, Matthew Butler, Carissa Dukes and Jiatao Michael Ye
Allergan, plc, Madison, NJ

Background: Liver enzyme levels are closely evaluated throughout the drug development lifecycle and are commonly used in the post-marketing setting for monitoring liver safety for patients. Understanding the distribution of liver enzyme levels in a real-world patient population can aid in describing background rates of elevated liver enzymes.

Objectives: To characterize rates of elevated liver enzymes among treated and untreated migraine patients in a real-world healthcare setting in the United States.

Methods: We conducted a retrospective database study using Optum Integrated Database. Patients aged 18 years or older diagnosed with migraine between January 1, 2013 and January 30, 2016 were identified using the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) and 10th Revision (ICD-10-CM). Patients were required to have at least 1 inpatient encounter, or, at least 2 outpatient encounters for migraine. The identified liver enzymes of interest were alanine aminotransferase (ALT) and aspartate aminotransferase (AST). A follow-up period of 1 year after earliest date of migraine encounter was used to capture AST and ALT values. Upper limit of normal (ULN) values were defined as 33 U/L for ALT and 36 U/L for AST in women and 40 U/L for ALT and 43 U/L for AST in men. Subgroups including: prescription treatment for migraine and migraine type (episodic/chronic) were analyzed as well as age and gender.

Results: Of 23,147 migraine patients analyzed, most were female (82.94%) between 18-65 years of age (86.11%). Patients with chronic migraine represented 5.63% of the sample and patients receiving prescription treatment for migraine represented 31.02%. During the 12-month follow up, the incidence proportions for patients with ALT or AST levels >1x ULN, >2x ULN, >3x ULN, and >5x ULN were reported as 16.4%, 3%, 1.8% and 0.9% respectively. The incidence of elevated enzymes >3x ULN was similar in patients with episodic migraine compared with chronic migraine (1.8% vs 1.24%, *P*= 0.20). Likewise, the incidence of elevated enzymes >3x ULN was not statistically significant for those receiving migraine treatment (1.67%) compared to no migraine treatment (1.81%) (*P*=0.53).

Conclusions: These data suggest approximately 1.8% of patients with migraine experience elevations of ALT or AST 3-fold or greater than the ULN in a real-world healthcare setting.

4316 | Hospital-diagnosed infections, community-based antibiotic prescriptions, and risk of subsequent Guillain-Barré syndrome: A 30-year nationwide population-based case-control study

Lotte S. Levison[1], Reimar W. Thomsen[1], Søren H. Sindrup[2] and Henning Andersen[1]
[1]*Aarhus University Hospital, Aarhus, Denmark;* [2]*Odense University Hospital, Odense, Denmark*

Background: Bacterial and viral infections may trigger Guillain-Barré syndrome (GBS) but the exact magnitude and duration of risk remain unclear.

Objectives: To investigate the association of different types of infection with risk of developing subsequent GBS.

Methods: Nationwide population-based case-control study including all patients with first-time hospital-diagnosed GBS in Denmark between 1987 and 2016, and 10 matched general population controls per case. Exposures were hospital-diagnosed infection for the entire

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

study period 1987 to 2016, and community-based antibiotic prescription in the period 2004 to 2016. We used conditional logistic regression to examine the relative risk of GBS associated with having a recent infection. Among GBS cases, we conducted an additional case-crossover analysis of having infection in a 60-day risk time window before becoming a GBS case versus in a 60-day control window 365 days earlier.

Results: Hospital-diagnosed infection within 60 days was observed in 4.3% of 2,414 GBS cases versus 0.3% of 23,909 controls, with a matched odds ratio (OR) of 13.7 (95% confidence interval [CI], 10.2-18.5). The strongest association with subsequent GBS was observed for lower respiratory infection (OR, 14.7; 95% CI, 8.5-25.6), gastrointestinal tract infection (OR, 15.5; 95% CI, 7.0-34.1) and septicemia (OR, 17.9; 95% CI, 6.0-53.3). Community antibiotic prescription within 60 days was observed in 22.4% of 1,086 GBS cases and 7.8% of 10,747 controls, with a matched OR of 3.5 (95% CI, 3.0-4.1). The risk of GBS declined substantially with time since infection, with ORs of 21.3 (95% CI, 14.5-31.2) and 4.7 (95% CI, 3.9-5.7) for hospital-diagnosed infection and community antibiotic prescription within the first month, but GBS risk was still increased 2.4-fold (95% CI, 1.1-5.5) and 1.5-fold (95% CI, 1.2-2.0) in the fifth month after infection. Risk estimates in the case-crossover analysis were similar to the results in the main analysis.

Conclusions: We found evidence for a strong, temporal association of community antibiotic use and in particular hospitalized infection with risk of subsequent GBS.

4443 | Co-occurrence of schizophrenia and dementia

Tobias Gerhard[1], T. Scott Stroup[2], Melanie Wall[2], Cecilia Huang[1] and Mark Olfson[2]

[1]*Rutgers University, New Brunswick, NJ;* [2]*Columbia University, New York, NY*

Background: Patients with schizophrenia have a significantly increased risk of developing dementia, including Alzheimer's Disease, but no guidelines exist for treating patients with both conditions. As a result, physicians face numerous clinical dilemmas, such as balancing the established efficacy of antipsychotics in older adults with schizophrenia against their known risks of premature mortality in older adults with dementia. Population-based studies examining the co-occurrence of schizophrenia and dementia have been limited to Northern Europe and Asia and provide only crude age stratification.

Objectives: To estimate the prevalence of diagnosed dementia in older US adults with schizophrenia compared to those without schizophrenia or other severe mental illnesses (non-SMI controls), stratified by single year of age.

Methods: Our study used a 50% random national sample of Medicare beneficiaries ≥65 years old with fee-for-service and Part D prescription drug coverage (2007-2017). Presence of schizophrenia was determined during a 1-year baseline period by 1 in- or 2 outpatient ICD9/10 codes for schizophrenia. The same baseline period was used to exclude patients with other SMI diagnoses from the control population. Dementia was defined using an algorithm previously validated against clinical dementia assessments (sensitivity 0.85; specificity 0.89). Once diagnosed, dementia was considered present for all following years. We then calculated the prevalence of dementia for older adults with schizophrenia and non-SMI controls, stratified by year of age.

Results: The study cohort included 75,326 older adults with schizophrenia (56.7% female) and 7,937,603 non-SMI controls (63.5% female) contributing 345,999 and 55,499,543 person years of follow-up, respectively. Dementia rates in the non-SMI controls were 1.5% (age 66), 6.5% (age 75), 21.8% (age 85), and 44.3% (age 95), comparable to US population estimates. Dementia rates in older adults with schizophrenia were 29.9% (age 66), 55.8% (age 75), 81.9% (age 85), and 91.3% (age 95), representing a 2-fold (age 95) to 20-fold (age 66) increased dementia prevalence. In sensitivity analysis, a more specific dementia algorithm resulted in marginally lower rates of diagnosed dementia, with no meaningful change in the prevalence ratio between the schizophrenia population and non-SMI controls.

Conclusions: Dementia diagnosis rates are dramatically increased in older adults with schizophrenia compared to age-matched non-SMI controls, particularly at younger ages. Clinical guidelines for the safe and effective management of patients with co-occurring schizophrenia and dementia diagnoses are urgently needed.

4497 | Infection dynamics in patients with multiple sclerosis over the past 15 years: A retrospective cohort study in the UK clinical practice research datalink

Melissa W.Y. Leung, Marloes T. Bazelier, Patrick C. Souverein, Hubert G.M. Leufkens and Romin Pajouheshnia

Utrecht University, Utrecht, Netherlands

Background: Disease-modifying treatments (DMTs) for multiple sclerosis (MS) are associated with causing an increased risk of infection. However, MS patients have an increased risk of mild and severe infections in the absence of DMT, which may be related to MS disease progression. Information on the dynamics of infection incidence in the MS population can help to disentangle the effects of DMTs from background MS prognosis.

Objectives: To examine over the past two decades the rates of infections in MS patients before and after MS diagnosis by patient subgroup.

Methods: A retrospective cohort study was conducted in the UK Clinical Practice Research Datalink (CPRD) Gold. 7219 patients diagnosed with MS were included from January 2003 to November 2019. Each MS patient was matched approximately 1:2 to patients from the general CPRD population by birth year, sex, practice and calendar year. Incidence rates per person year (IR) of urinary tract infection (UTI), skin and subcutaneous tissue infection, sepsis, respiratory infection, and gastrointestinal infection were calculated per study year. The average change in infection rate 5 years after patients' MS diagnosis

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

compared to 5 years before was calculated across the whole study and per year. Analyses were stratified by age at diagnosis, sex, number of infections within 12 months prior to cohort entry and whether the first recorded MS diagnosis was before or after 2003. All analyses will be replicated in a larger CPRD Aurum cohort (13752 MS patients).

Results: The incidence rate of infections in MS patients was 1.9 times higher than the general population over the study period (MS: 0.53 [0.52-0.53] vs non-MS: 0.28 [0.27-0.28], with UTIs most frequent (MS: 0.19 [0.19-0.20], non-MS: 0.056 [0.055-0.058]). A higher infection rate was found in CPRD Aurum (MS, any infection IR: 0.62 [0.62-0.63]). Infection rates were higher in women than men (0.59 [0.58-0.60], 0.36 [0.35-0.37], respectively). The incidence of infections was on average 30 percent higher within 5 years after MS diagnosis (IR 0.45, 95% CI 0.44-0.46) than the 5 years before (IR 0.35, 95% CI 0.34-0.35). The infection rates and differences in infection rate pre- and post-diagnosis declined over the study period across the subgroups. Full analyses in CPRD Aurum will be presented at the conference.

Conclusions: The rates of five key types of infection decreased between 2003 and 2018, but remained higher than in the general population. Consideration of patient characteristics associated with the risk of infection may be valuable for disease management decisions in MS.

4566 | Incidence, survivorship, and treatment of motor neuron disease in Hong Kong: A population-based study

Min Fan[1], Gary K.K. Lau[2,3], Xue Li[1,4,5], Ian C.K. Wong[1,6] and Celine S.L. Chui[1]

[1]Centre for Safe Medication Practice and Research, Department of Pharmacology and Pharmacy, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong; [2]Centre for Prevention of Stroke and Dementia, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom; [3]Division of Neurology, Department of Medicine, University of Hong Kong, Hong Kong, Hong Kong; [4]Department of Paediatrics and Adolescent Medicine, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong; [5]Department of Social Work and Social Administration, Faculty of Social Sciences, University of Hong Kong, Hong Kong, Hong Kong; [6]Research Department of Policy and Practice, University College London School of Pharmacy, London, United Kingdom

Background: Motor neuron diseases (MND) are a group of neurodegenerative disorders that affect the motor neurons in the brain and spine. Riluzole is an approved drug for treatment of amyotrophic lateral sclerosis (ALS), a subtype of MND. However, there are lack of local evidences on its effectiveness.

Objectives: To estimate the epidemiology and survivorship of motor neuron disease (MND) in a population-based sample in the Hong Kong.

Methods: This is a population-based study of people with MND from 1993 to 2018 in Hong Kong. The data is collected from the Clinical Data Analysis and Report System, which covered all public hospitals in Hong Kong. The patients having primary diagnosis (ICD-9-CM: 335.2-335.29 and ICD-10: G12.2) are the cohort of interest for the study. Descriptive statistics on patients' demographic characteristics, clinical features, prescriptions, and prognosis were reported. The Kaplan-Meier estimator was used to estimate the survival function among riluzole users and non-users and compared by the log-rank test. The data cleaning and analysis will be performed by R (version 3.6.0).

Results: In the study period, 1 949 new cases with MND diagnosis were identified. From 1995 to 2018, the incidence and prevalence of MND increased from 1.04 to 1.3 (p=0.001) and from 1.40 to 8.04 (p<0.001) per 100 000 persons respectively. The average age at first diagnosis for MND is 60.6 (SD 15.1), and the proportion of MND in male was 64.7%. Among them, 76.5% (n=1 491), 87.8% (n=1 711) and 92.6% (n=1 804) had hypertension, diabetes, and depression related diagnosis. The median survival time after the first diagnosis was 1.37 years. 12.8% (n=250) of the MND patients received at least one prescription of riluzole. Among them, 95.6% (n=239) were ALS. No statistical difference was found among survival between riluzole users and non-users, either in MND or ALS.

Conclusions: The incidence of MND patients is increasing from 1993 to 2018 in Hong Kong. Majority of them have comorbidities and the median survival year is 1.37. However, more prospective studies are needed for the clinical benefit for riluzole.

4639 | All-cause mortality, suicide and self-harm in patients with treatment-resistant depression

Frederikke Gronemann[1], Martin Balslev Jørgensen[2], Merete Nordentoft[2,3], Per Kragh Andersen[4] and Merete Osler[1,4]

[1]Center for Clinical Research and Prevention, Frederiksberg, Denmark; [2]Mental Health Centre Copenhagen, Copenhagen, Denmark; [3]Lundbeck Foundation Initiative for Integrative Psychiatric Research iPsych, Copenhagen and Aarhus, Denmark; [4]University of Copenhagen, Copenhagen, Denmark

Background: Patients with Treatment-resistant depression (TRD) seem to have an increased risk of mortality compared to patients with non-TRD. This has, however, only been scarcely investigated in large population-based studies.

Objectives: To investigate all-cause mortality, suicide and self-harm among patients with TRD in a nation-wide cohort of patients with depression.

Methods: In this cohort study, all citizens in Denmark diagnosed first time with depression at a hospital, either as in- or outpatient, between 1 January 1996 and 31 December 2014 were identified in Danish registers using the international Classification of Diseases, Tenth Revision (ICD-10), codes F32 and F33. Patients with a prior hospitalization for a comorbid diagnosis of bipolar affective disorder (ICD-10:F30-F31), other affective mood disorders (ICD-10:F38-F39), persistent mood disorder (ICD-10:F34) or schizophrenia spectrum (ICD-10:F20-F29) disorder were not included. TRD was defined as two shifts in antidepressant treatment, assessed from one year prior to depression diagnosis until one year after. Patients characterized with TRD before or

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

at time of MDD diagnosis were not included (N=10,602). Information on mortality and suicide was derived from the Causes of Death Register, while data on self-harm was obtained from the National Patient Register using ICD-codes X60-64, X66-84, T39, T42-43 and R458. Data was analyzed using Cox Proportional Hazard Regression with TRD as a time-varying covariate.

Results: Of 195,541 patients diagnosed with depression, 15.2% was characterized with TRD. We found an increased rate of both suicide (aHR 1.34, 95% CI 1.20-1.51) and self-harm (aHR 1.42, 95% CI 1.35-1.48) in patients with TRD. When stratified by depression severity, the rate of suicide was higher among TRD-patients diagnosed with mild (aHR 1.55, 95%CI 1.30-1.85) and moderate (aHR 1.40, 95%CI 1.17-1.67) depression, while no differences in suicide rate was observed in patients with severe depression. All-cause mortality was lower in patients with TRD (aHR 0.84, 95%CI 0.82-0.86) compared to patients with non-TRD.

Conclusions: Overall, patients with TRD have higher rates of both suicide and self-harm compared to patients with non-TRD, whereas TRD was associated with lower all-cause mortality.

4700 | Postnatal depression and infant "5-in-1" vaccine adherence in the United Kingdom

Holly C. Smith, Fahima Choudry and Irene Petersen
University College London, London, United Kingdom

Background: All infants in the United Kingdom are offered three doses of the 5-in-1 vaccination at 2, 3 and 4 months of age. This combined vaccination protects against diphtheria, tetanus, pertussis (whooping cough), polio and Hib disease (*Haemophilus influenzae* type b). There is a suggestion that there may be a lower uptake of infant vaccinations in children of mothers with postnatal depression; however, the evidence thus far has been mixed and the link between postnatal depression and infant vaccine uptake remains inconclusive.

Objectives: To examine if adherence of the infant 5-in-1 vaccination is lower in mothers who have postnatal depression.

Methods: We conducted a retrospective cohort study using UK primary care electronic health records from The Health Improvement Network (THIN) database. Linked mother-infant pairs were identified with infant date of birth between 1 January 2006 and 31 December 2015. Mother's records were examined to identify postnatal depression in the first year after childbirth. The primary outcome measure was completion of all three doses of the infant 5-in-1 vaccination before one year of age. Poisson regression models were used to compare the likelihood of infant 5-in-1 vaccination uptake in children of women with postnatal depression to women with no recorded postnatal depression.

Results: Of the 219,810 women included in the study, 23,151 (10.5%) had a record of postnatal depression in the first year after birth. There was no difference in infant's 5-in-1 vaccination completion between mothers with postnatal depression and those without (adjusted IRR: 1.01, 95% CI: 0.99-1.02). Those from more socially deprived areas were less likely to complete their infant vaccinations compared to those from the least deprived areas (IRR: 0.92, 95% CI: 0.90-0.92). The likelihood of completing infant 5-in-1 vaccination reduced over time, comparing 2006-07 to 2014-2015 (IRR: 0.91, 95% CI: 0.90-0.92).

Conclusions: Infants of mothers with postnatal depression were just as likely to have completed their 5-in-1 vaccine as infants of mothers without postnatal depression.

4915 | Infectious processes and schizophrenia: Is there any correlation?

Túlio Tadeu R. Sarmento[1], Isabella F. Zuppo[1,2], Pâmela S. Azevedo[1], Ludmila P. Gargano[1,2], Natália D. Brandão[1,2], Juliana Alvares-Teodoro[1,2], Francisco A. Acurcio[1,2], Augusto A. Guerra[1,2], Mariana B. Deleprane[2] and Rafael L.R. dos Santos[2]
[1]*SUS Collaborating Centre Technology Assessment and Excellence in Health, Belo Horizonte, Brazil;* [2]*Federal University of Minas Gerais, Belo Horizonte, Brazil*

Background: Schizophrenia is a severe, chronic and disabling psychotic disorder whose etiology is not fully understood, although it is postulated that genetic and environmental factors are involved in its pathogenesis. Understanding the etiology and pathogenesis of schizophrenia can fill a gap that will support the research and development of new drugs, in addition to improve the care of psychotic disorders.

Objectives: To evaluate if infectious processes are related to the etiology of schizophrenia using real-world evidence, and if positive, which pathogens ones are more important.

Methods: A systematic review (SR) and meta-analysis assessing a possible association between infections and schizophrenia was carried out by consulting the MEDLINE, EMBASE, LILACS and Cochrane Library databases, besides gray literature. Were included SR, cohort and case control studies that assessed the presence of schizophrenia and occurrence of previous infections. The selection of studies was carried out by two independent reviewers and, in cases where there was disagreement, it was resolved by a third reviewer. The meta-analysis was conducted using PythonMeta version 1.11 software.

Results: Our search retrieved 1198 studies and 66 were included in the meta-analysis: two cohorts and 64 case-control studies. There was no statistically significant difference in the meta-analysis of the cohorts assessing the risk related to the occurrence of schizophrenia in patients with a viral infection during childhood. Regarding the results from case-control studies, the meta-analysis suggest a greater chance of schizophrenia in individuals with antibodies against bacteria [OR 2.03 (IC95% 1.06 - 3.91)], protozoa [OR 2.01 (IC95% 1.42 - 2.84)] and virus [OR 1.57 (IC95% 1.15, 2.15)]. In addition, some studies have evaluated whether viral infections during pregnancy could be related to the onset of schizophrenia in the child, however, the results obtained have shown no statistical significance in this scenario.

Conclusions: Real-world evidence suggests that individuals with a history of infections by viruses, bacteria and protozoa are more likely to

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

develop schizophrenia. In addition, no evidence was found that infections during pregnancy women may be related to the onset of schizophrenia in children. The results presented here can support further discussions in order to better elucidate the relation between infections and schizophrenia, in addition to elucidate possible future paths for pharmaceutical development.

4972 | Characteristics of multiple sclerosis by ethnoracial groups in medicaid and electronic health records

Nydjie Grimes, Cortney Hayflinger and Cynthia Jones
Biogen, Cambridge, MA

Background: Publications on African American, Hispanic, and Asian populations with multiple sclerosis (MS) are available; however, large population-based samples are needed to better understand these subgroups.
Objectives: This study describes demography, comorbid conditions, and drug utilization among ethnoracial populations with MS in Medicaid and electronic health records (EHR).
Methods: MS patients were selected from 2 large databases (2013-2017): 1) Truven Health Marketscan® Medicaid and 2) Optum® EHR. MS cases were defined as those with ≥ 2 medical claims for MS. Non-white MS cases were defined as patients identified as black, Asian, or other. Hispanic MS cases were defined as patients identified as Hispanic. White and non-Hispanic controls were selected and matched on age (10-year bands), gender, time in the database, and pharmacy benefit eligibility. Comorbid diagnoses were grouped using the Clinical Classification System. Medications were classified using the Uniform System of Classification. Comparisons of comorbidities between cases and controls were estimated using prevalence rate ratio (PRR) and 95% confidence intervals.
Results: Among 9,728 non-white MS cases identified in Truven Medicaid, 87%, 3%, and 10% were African American, Hispanic and other, respectively. In Optum EHR, 23,208 non-white MS cases were identified; 75%, 3%, and 22% were African American, Asian, and Hispanic, respectively (not mutually exclusive). The mean age (years) at onset for these subgroups was 45.3 in Truven Medicaid and 48.7 in Optum EHR, and 78% were female. Comorbidities were similar in non-white cases and white controls, with other nervous system disorders, other connective tissue disease, diseases of the urinary system, and hypertension among the most prevalent conditions. Among these, a statistically significant difference was only noted for hypertension. The top medications used among non-white MS cases were anti-infectives, narcotic analgesics, corticosteroids, anti-arthritis systemic medications, and anti-depressants. Subgroup stratifications are presented.
Conclusions: Our results indicate that overall characteristics of non-white and Hispanic MS patients are similar to white and non-Hispanic MS patients. Further analyses in these datasets are warranted to evaluate differences in MS severity and course, treatment patterns, and overall healthcare utilization as identified in other publications.

5032 | Prevalence of anxiety, depression and drug utilization of antidepressants among cancer patients in the inpatient settings: A cross-sectional study in Jordan

Abdallah Y. Naser[1], Anas Nawfal Hameed[1], Nour Mustafa[2], Hassan Alwafi[3] and Haya Khalil[2]
[1]Isra University, Amman, Jordan; [2]King Hussein Cancer Center, Amman, Jordan; [3]Umm Alqura University, Mecca, Saudi Arabia

Background: Psychiatric illnesses are common among cancer patients as the presence of cancer itself and receiving its treatment lead to depression and anxiety in many cases. Psychiatric illnesses are associated with poor adherence to cancer therapy and negatively affect disease management and therapy outcomes.
Objectives: To investigate the prevalence of anxiety, depression and drug utilization of antidepressants among cancer patients within the inpatient settings.
Methods: A cross-sectional study was conducted between October 2019 and February 2020 at the inpatient department in King Hussein Cancer Center in Jordan. patients' psychological status was assessed using the Hospital Anxiety and Depression Scale (HADS) and the Generalized Anxiety Disorder 7-item (GAD-7) scale. Prevalence rate of depression was estimated by dividing the number of patients who exceeded the borderline score (10 or more) of the HADS scale by the total number of the patients. Same procedure was followed to identify patients with anxiety and applied using the two scales (HADS (using a score of 10 or more) and GAD-7 (using a score of 15 or more)). Risk factors of anxiety/depression were identified using logistic regression.
Results: A total of 399 cancer patients were involved in this study. The prevalence rate of depression is around 37.1%. The prevalence rate of anxiety was comparable using the HADS and the GAD-7 scale and was 35.6% and 37.6%, respectively. Cancer metastasis was important predictor of depression (odds ratio (OR) 2.62 (1.61 - 4.28)) and anxiety using the two scales (OR: 2.10 (1.29 - 3.42) and 2.23 (1.32 - 3.74). Reaching stage three (OR: 5.26 (1.05 - 26.41)) and four (OR: 2.73 (1.61 - 4.62)) in the metastasis were other important predictors of depression. Reaching stage four in the metastasis was associated with higher odds of anxiety (OR: 2.39 (1.42 - 4.04)). Being treated with combination of surgery and chemotherapy was a protective factor from anxiety (OR: 0.54 (0.33 - 0.86)). Despite the high prevalence of depression among the study participants, only 14.2% were receiving antidepressant medications. The most commonly used antidepressant therapeutic class was selective serotonin reuptake inhibitors (23.8%).
Conclusions: The prevalence of depression and anxiety is high among cancer patients in the inpatient settings. High percentage of the patients are unaware about their illness, undiagnosed and

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

consequently do not receive treatment for their psychiatric illnesses. Thorough psychological assessment should be directed towards critically ill cancer patients.

5134 | Medication use among migraine sufferers: An analysis of electronic medical records

Jessica D. Albano, Kelly Oh and Sara Ephross
Syneos Health, Morrisville, NC

Background: Twelve percent of the US population, 6% men and 18% women, suffer migraines. Treatment has primarily relied on general pain medications, acute migraine therapies and preventive use of drugs developed for other conditions. Emergence of a new class of prophylactic migraine drugs, calcitonin gene-related peptide inhibitors (anti-CGRPs), has the potential to significantly impact the treatment landscape.

Objectives: To describe demographic, clinical and treatment characteristics of migraine patients using a US database of electronic medical records.

Methods: EMR data of patients ≥15 years of age with at least two distinct migraine diagnoses (ICD-10 G43) within the past 5 years were analyzed in TriNetX "Analytics" (Cambridge, USA; Feb 2020), a live database of ~60M US patients. Disease diagnoses within one year prior to the first migraine diagnosis and medication use following the first migraine diagnosis are reported.

Results: A total of 65,147 men and 318,406 women migraine sufferers were included. Approximately 75% of patients were white and mean age was 45 years. Common comorbid conditions among men and women included disorders of the nervous system (29% and 27%), musculoskeletal system (27% and 29%), endocrine/metabolism (23% and 24%) and circulatory (22% and 17%). Mental/behavioral/neurodevelopmental disorders were diagnosed for 21% of both groups. Analgesics were used by 80% and 83% of men and women; most common were acetaminophen (50% and 55%), ibuprofen (23% and 30%) and aspirin (21% and 18%) among men and women, respectively. Opioids were used by up to 25% of men and 27% of women. Sumatriptan was used by 31% of men and 35% of women. Anticonvulsants were used by 42% of men and 48% of women with topiramate (19% and 29%) and gabapentin (21% and 23%) most frequently prescribed. Antidepressants were used more frequently among women (57%) compared to men (47%). Sedatives were used by 43% of men and 48% of women. Beta blockers were used by 30% of men and 29% of women, while calcium channel blockers were used by 18% of men and 15% of women. Anti-CGRPs were used by 1.8% and 2.3% of men and women, respectively.

Conclusions: Male and female migraine sufferers experience similar, high rates of comorbid conditions and concomitant medication use. Although CGRPs have been widely available for more than a year, they make up a small proportion of migraine prescriptions. Future analyses will focus on treatment pathways including those leading to anti-CGRP initiation.

Disease Epidemiology/Clinical Course -> Other

52 | Identifying patients with chronic kidney disease in a population-based laboratory database

Uffe Heide-Jørgensen[1], Christian F. Christiansen[1], Henrik Birn[1,2], Reimar W. Thomsen[1] and Søren V. Vestergaard[1]
[1]*Aarhus University Hospital, Aarhus, Denmark;* [2]*Aarhus University, Aarhus, Denmark*

Background: Hospital diagnoses of chronic kidney disease (CKD) are likely incomplete and do not reflect the time of onset, as most patients with CKD are managed in general practice. Population-based laboratory databases are attractive data sources for patient identification in pharmacoepidemiological studies, as CKD is defined by laboratory findings in the current guidelines.

Objectives: To apply different algorithms for identifying CKD from hospital and laboratory data, and to describe the resulting patient cohorts.

Methods: We used population-based laboratory-, hospital-, and administrative databases in Northern Denmark to identify and follow patients with CKD as defined by six algorithms in 2009-2016. Five algorithms were based on laboratory data, requiring A) one measurement of estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m^2, B) two such measurements at least 90 days apart, C) two such measurements at least 90 days apart with no eGFR > 60 mL/min/1.73m^2 observed in-between, D) two such measurements 90-365 days apart, E) two such measurements or two measurements of urine albumin creatinine ratio > 30 mg/g at least 90 days apart. Algorithm F included patients with a hospital diagnosis of CKD. We estimated prevalence and incidence of CKD in the adult population, described baseline characteristics, and estimated 1-year mortality in the resulting cohorts after applying each algorithm.

Results: Laboratory based algorithms A-E yielded CKD prevalences of 8.3%, 5.6%, 4.8%, 4.6%, and 5.9% as of 1 January 2009, and incidences of 8.9, 7.3, 5.9, 8.8, and 7.3 per 1000 person-years. The resulting cohorts A-E included 103,435; 84,688; 68,994; 75,031; and 100,957 patients, with corresponding median ages of 71, 74, 76, 75, and 73 years. The median eGFR levels at inclusion was 56, 55, 53, 54, and 56 mL/min/1.73m^2, and the median time since first ever observed eGFR < 60 mL/min/1.73m^2 was 0, 13, 17, 11, and 13 months. The 1-year mortalities were 8.1% (95% confidence interval 8.0-8.3), 8.1% (8.0-8.3), 7.9% (7.7-8.1), 8.6% (8.5-9.0), and 7.2% (7.1-7.4). Algorithm F resulted in a CKD prevalence of only 0.8%, and an incidence of 2.4 per 1000 person-years. The resulting cohort included 27,947 patients with a median age of 72 years, median eGFR of 47 mL/min/1.73m^2, and median time since first ever observed eGFR < 60 mL/min/1.73m^2 of 70 months. The 1-year mortality was 21.6% (21.2-22.1).

Conclusions: The choice of algorithm used to identify CKD patients from databases affected estimated occurrence and cohort composition. The greatest difference was seen between algorithms based on laboratory data compared to hospital diagnoses.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 53 | Identification of risk factors associated with mortality in neonatal sepsis patients

Vijayanarayana Kunhikatta[1], Puspita Sahu[1], Meenakshi Srinivasan[1], Shivakumar M.[2] and Leslie Edward Lewis[3]

[1]Department of Pharmacy Practice, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal, Karnataka State, India; [2]Department of Pharmacology, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Karnataka State, India; [3]Department of Paediatrics, Kasturba Medical College, Manipal, Manipal Academy of Higher, Manipal, Karnataka State, India

Background: Neonatal sepsis is an important cause of mortality among neonates in developing countries accounting for 30-50% of total deaths each year and is major public health challenge. Mortality from neonatal sepsis may be as high as 50% for infants who are not treated and even among treated there may be several maternal and neonatal factors influence poor outcomes.

Objectives: Objective of the study was to find out in-hospital neonatal sepsis rate, associated motility and identify the risk factors associated with mortality.

Methods: A retrospective observational study was conducted among neonates admitted to neonatal intensive care unit (NICU), in a tertiary care teaching hospital. Institutional ethics committee approval was obtained prior to the study. Neonates with culture positive sepsis, admitted during January 2012 to December 2016 at the level 3 NICU were identified using ICD 10 Code P36.0-9 from inpatient medical records, based on the inclusion and exclusion criteria. Data on demography, birth weight, mode of delivery, gestation age, maternal comorbid conditions, maternal surgical procedures done, maternal drug use, neonatal outcomes were collected from the patient medical records. Multiple logistic regression was used to identify the factors associated with mortality and calculation of adjusted odds ratio (AOR).

Results: A total of 613 neonates were identified with culture positive sepsis from the 4690 neonates admitted in NICU during the study period. Total rate of sepsis in the NICU was 13.07 per 100 neonates and mortality rate was found to be 25.4%. Multiple logistic regression analysis showed, extremely low birth weight (AOR: 6.17; CI: 3.47-10.96; p<0.001), extreme preterm (AOR: 5.76; CI: 2.61-12.71; p<0.001), very pre-term (AOR: 2.55; CI: 1.61-4.04; p<0.001), maternal steroid prophylaxis (AOR: 1.64; CI: 1.04-2.58; p<0.033) and pregnancy induced hypertension (AOR: 1.67; CI: 1.09-2.56; p<0.018), were statistically significant independent risk factors associated with mortality. However, breast feeding (AOR: 0.3; CI: 0.18-0.49; p<0.001) has shown statistically significant protective effect.

Conclusions: Both maternal and neonatal factors were associated with increased mortality in neonatal sepsis. Therefore, varied strategies should be implemented for better management of the disease.

70 | The impact of socioeconomic status on the risk of total hip arthroplasty during 1995 to 2017 in Denmark

Nina M. Edwards[1], Claus Varnum[2,3], Søren Overgaard[3,4] and Alma B. Pedersen[1]

[1]Aarhus University Hospital, Aarhus, Denmark; [2]Vejle Hospital, Vejle, Denmark; [3]University of Southern Denmark, Odense, Denmark; [4]Odense University Hospital, Odense, Denmark

Background: People are widely affected by their socioeconomic status (SES) even in health care, where low SES is associated with higher risk of developing osteoarthritis (OA). Total hip arthroplasty (THA) is an effective procedure for reducing pain and improving function and quality of life in patients suffering from disabling OA. Thus, it is plausible to expect an increased need of THA among individuals with low SES. One previous study examined the use of THA in relation to SES in four European countries finding pro-rich-area inequality. However, the study has several limitations including missing data on the individual level measures of SES. Our hypothesis is therefore, that there is a socioeconomic inequality in THA utilization in Denmark.

Objectives: Examine the association between SES and the risk of THA and whether the association is age- or time-dependent.

Methods: This is a population based case-control study, where we included all patients undergoing primary THA due to OA (cases) in Denmark from the 1st of January 1995 to the 31st of December 2017 using the Danish Hip Arthroplasty Register. Using the Danish Civil Registration System each case was matched on sex, region of residence and surgery date with 5 controls from the background population. We retrieved individual-level data on SES markers (education, cohabitation, income and liquid assets). We performed logistic regression to estimate adjusted odds ratios (aOR) with 95% confidence intervals for THA, adjusting for SES markers and comorbidity according to Charlson.

Results: A total of 108,946 THA cases and 544,730 population controls were identified. The aOR for the risk of THA with the lowest education vs. highest education was 1.42 (1.32-1.53) for the age group 45-55. The association between education and THA decreased with increasing age. The aOR for the risk of THA for patients who lived alone vs. lived with a partner was OR 0.93 (CI: 0.91-0.96). The aOR for the age group 45-55 with the lowest vs. highest income was 1.12 (1.02-1.23) and was 0.75 (0.70-0.80) for those with the lowest vs. highest liquid assets. The aOR for the risk of THA with the lowest education vs. highest was 1.23 (1.15-1.31) in the years 1995-2000 and decreased to 1.01 (0.97-1.05) in the years 2013-2017. For the lowest income vs. the highest the aOR was 1.22 (1.12-1.32) in 1995-2000 and decreased to 0.84 (0.80-0.89) in 2013-2017.

Conclusions: The association between lower level of education, lower level of income, and living alone and the high risk of THA was age dependent. The inequality seen in the risk of THA by education decreased over time suggesting a time trend towards less socioeconomic inequality.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 92 | Association between dietary diversity and all-cause mortality among Chinese adults 65 years of age or older, a community-based cohort study

Liyuan Tao, Lin Zeng, Nan Li, Yanyan Shi, Hua Zhang, Xiaoxiao Wang, Hongling Chu, Lin Zhuo, Kaiwen Ni and Xiaoli Liu
Peking University Third Hospital, Beijing, China

Background: Diet is a well-established major modifiable risk factor for multiple chronic disease and mortality, but few studies have evaluated the association of dietary diversity and mortality in older adults.
Objectives: We aimed to examine the prospective association between dietary diversity and the risk of all-cause mortality in a community-based cohort study of older Chinese adults.
Methods: In this prospective cohort study, we invsetigated the association between dietary diversity and all-cause mortality among 17949 community-based participants aged 65 years or old in China. The consumption on the frequencies of food groups was collected at baseline, and a dietary diversity score (DDS) was calculated. Survival status and date of death were collected during the follow-up survey. We used univariate and multivariable Cox proportional hazards models to estimate hazard ratios (HRs) and 95% confidence intervals for all-cause mortality with higher DDS (score: 8-9) versus lowest DDS (score 0-1).
Results: We identified 8445 death events over 57,685 person-years of follow up. Compared with participants in the lowest DDS group (score 0-1), higher DDS was associated with lower mortality risk in the univariate models. After adjusting for potential confounders, participants in the higher DDS group had a 9%-30% lower risk in all-cause mortality (p trend<0.001) compared to participants in the lowest DDS group. The inverse relationship between diet diversity score and all-cause mortality was also statistically significant in four food groups (vegetables, fish, fruits, and nuts). We observed similar results after including different confounders in model 2 and model 3 in the sensitivity analyses.
Conclusions: Dietary diversity is inversely associated with all-cause mortality among the Chinese elderly, especially in the oldest old and men. These findings suggest that increasing dietary diversity may lower mortality rates in older population and that tailored interventions on improving dietary diversity may improve health and increase survival in this population.

95 | Evaluation of reporting quality for prediction models of HBV-related hepatocellular carcinoma by tripod statement

Liyuan Tao, Lin Zeng, Nan Li, Yanyan Si, Hua Zhang, Xiaoxiao Wang, Hongling Chu, Kaiwen Ni, Xiaoli Liu, Siyan Zhan and Lin Zhuo
Peking University Third Hospital, Beijing, China

Background: The design, conduct, analysis, and reporting of risk prediction model studies should be complete, transparent, and accurate. To improve the reporting quality, a guideline for the Transparent Reporting of a multivariable prediction model for Individual Prognosis Or Diagnosis (TRIPOD) with a checklist of 22 items was developed and published in 2015, and previous studies showed that quality of reporting of prediction model studies is poor. However, none of them assessed the reporting quality in viral hepatitis domains.
Objectives: To assess reporting quality of predication models for viral hepatitis using the TRIPOD checklist.
Methods: We searched PubMed, Embase, and Web of science from inception to 1 June 2019, to identify potentially relevant scientific papers reporting original research. We assessed the reporting quality of eligible articles according to the TRIPOD checklist.
Results: A total of 38 papers were included in the final analysis. Only 10 (26.32%) papers completed reporting for >75% items per publication. Among all the TRIPOD items, the poor reporting items were title (26.32% [10/38]), descriptions of outcome (24.24% [8/33]), predictors (15.15% [5/33]), sample size (0.00% [0/38]), missing data (i2.63% [1/38]), and risk groups (36.00% [9/25]) in the methods. The median proportion of completeness of reporting per publication was 70.56% (IQR: 63.33%-75.86%). Completeness of reporting per publication did not statistically significant in different year of publication, type of study, and study design. In the multivariate model, after adjustment of potential confounders, impact factor of published journal (OR=10.14, 95% CI: 1.66-61.84) and sample size (OR=22.77, 95% CI: 1.10-472.57) was independently associated with sufficient reporting.
Conclusions: The reporting quality of the overall and some key items were not sufficient in studies focusing on developing and external validation of prediction models for HBV-related HCC development or prognosis. More attentions should be paid on the complete and transparent reporting.

2352 | Elevated risk of hospitalization for infection in anemic patients in Japan at the beginning of impaired renal function

Tomomi Kimura[1], Satoshi Onozawa[2], Masataka Morita[2], Osamu Yamamoto[2] and Tadao Akizawa[3]
[1]Astellas Pharma US Inc., Northbrook, IL; [2]Astellas Pharma Inc., Tokyo, Japan; [3]Showa University, Shinagawa City, Japan

Background: Anemia in chronic kidney disease (CKD) is known to be associated with an increased risk of renal and/or cardiovascular outcomes, as well as higher mortality. Anemia is also associated with chronic infection, but the association with acute, severe infection at early stage CKD has not yet been elucidated in the Japanese population.
Objectives: To descriptively compare the incidence and hazard ratio of the hospitalization for infection between anemic and non-anemic patients with early stages of impaired renal function.
Methods: This was a retrospective cohort study using annual health checkup data and insurance claims between 2008 and 2019 for employees and their dependents aged 74 years or younger, provided by JMDC. Subjects aged 18 years or older who had an estimated glomerular filtration rate (eGFR) of ≥60 ml/min/1.73m^2 at the previous checkup, and first experienced an eGFR <60, were enrolled and followed until hospitalization for infection or end of data period

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(including death). Anemia was defined with baseline hemoglobin value, age, and sex according to Japanese guidelines for Renal Anemia in Chronic Kidney Disease, regardless of treatment for anemia. Hospitalization for infection was defined as those with an anti-infective prescription on the admission date and infectious disease-related diagnosis codes on the inpatient claims. Propensity score for anemia (or non-anemia) at baseline was estimated and the stabilized inverse-probability-weighted Kaplan-Meier estimates were calculated. Hazard ratio was estimated using the Cox proportional hazard model adjusted for baseline age, sex, eGFR, proteinuria, Charlson comorbidity index score, HbA1c, systemic blood pressure, and current smoking status.

Results: In total, 32,870 subjects were enrolled and followed-up in an average of 4.1 years. At baseline, 1,396 (4.2%) of the subjects were anemic. The crude incidence rates per 1000 person-years (95% confidence interval [CI]) were 7.64 (5.55-10.26) in anemic group vs 2.30 (2.05-2.58) in the non-anemic group. Unweighted and weighted 5-year Kaplan-Meier survival estimates (95% CI) of time to first hospitalization for infection in the anemic and non-anemic groups were 96.5 (95.2-97.5) vs 98.9 (98.8-99.1) and 97.6 (95.7-98.7) vs. 98.9 (98.8-99.0), respectively. The adjusted hazard ratio (95% CI) was 2.349 (1.672-3.301).

Conclusions: Anemia in very early stage CKD was associated with elevated risk of hospitalization for infection, independent of the level of renal impairment.

2370 | Doxycycline adherence scale: The impact on the incidence of leptospirosis among flood affected South Indian population

Jose J. Kochuparambil[1] and Aleena Issac[2]
[1]*St. Joseph's College of Pharmacy, Cherthala, Alappey, India;* [2]*Nirmala College of Pharmacy, Muvattupuzha, India*

Background: Leptospirosis is a zoonotic disease caused by *Leptospira* after flood or heavy rain. Doxycycline is the most commonly used prophylactic antibiotic for the prevention of leptospirosis. Adherence to doxycycline is crucial in case of moderate to severe exposure to contaminated water. Non-adherence and unawareness towards chemoprophylaxis after the flooding in the Indian state of Kerala on the year 2018 contributed towards an epidemic. This incident pointed towards the need of developing and implementing a scale to assess adherence towards doxycycline.

Objectives: To develop and implement a scale to measure adherence to the administration of doxycycline.

Methods: A five-item doxycycline adherence scale was prepared based on the leptospirosis policy statement of the health ministry and insights from the past incidence of leptospirosis. This prospective, interventional study included 200 flood victims aged 18 years and older, displaced from the home and staying in the rescue homes. They were interviewed for basic demographic details and the doxycycline adherence scale was given to them for the next 5 weeks on a weekly basis by 5 different interviewers. Half of the study sample was provided with counseling on rational use of doxycycline. The impact of counseling and adherence to therapy in reducing the incidence of leptospirosis was analyzed by comparing the response from infected to the non-infected responders with chi-square method with p value < 0.05 to be significant.

Results: 161 (80.5%) people were adherent to the doxycycline chemoprophylaxis and 17 cases of leptospirosis (9.5%) were reported among the cohort by the health workers. The number of cases of leptospirosis reported among the adherents vs non-adherents (3% vs 31%, $p < 0.001$) and among the population that received counseling vs no counseling (2% vs 15%, $p < 0.001$) showed statistically significant results.

Conclusions: Proper adherence and providing counseling regarding the rational use of medicines and health habits can decrease the incidence of leptospirosis. Implementation of doxycycline adherence scale can help to monitor the patients and provide corrective intervention regarding non-adherence.

2467 | Clinical characteristics of sepsis patients by survival status: An analysis of electronic medical records

Brian Buysse[1], Claire Le Nguyen[1] and Jessica Albano[2]
[1]*Syneos Health, Farnborough, United Kingdom;* [2]*Syneos Health, Morrisville, NC*

Background: Sepsis-related mortality is estimated to be 20% globally. There is lack of understanding characteristics of patients with fatal sepsis.

Objectives: To describe clinical characteristics of sepsis deaths and of those who survived sepsis using a US database of electronic medical records (EMRs).

Methods: EMR data of patients with newly diagnosed sepsis within 12 months (ICD-10 codes included A40 and A41) in the past 5 years was analyzed in TriNetX Analytics (TriNetX, Cambridge, US; January 2020), a live database of ~60M US patients. Disease diagnoses, microbiological investigations and antimicrobial therapy were assessed in two cohorts, one of patients who had died within 1 month of sepsis diagnosis (deceased) and one of patients who had lived for at least 6 months (survived).

Results: Included were 21,241 deceased and 90,304 surviving patients. Deceased patients were older at sepsis diagnosis than surviving patients (mean 69.3 and 57.4 yrs, respectively) and had greater prevalence of chronic conditions recorded in the year before sepsis. For instance, metastatic cancer was 4 times more frequent in deceased than in surviving patients. Microbiological investigations within 7 days before and including day of sepsis were done in only 34% of deceased and 38% of surviving patients. About 25% of both cohorts received antimicrobials within 30 days before sepsis. Antibiotics were given to ~80% of both cohorts in the 7 days following and including day of sepsis diagnosis, and this was higher in patients with microbiological investigations (87% in both cohorts). In deceased patients, vancomycin plus piperacillin-tazobactam was the most common first-line (15% of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients) and second-line (10%) therapy. In contrast, ceftriaxone monotherapy was the most common first-line antibiotic therapy in surviving patients (13%)—only 7% received vancomycin plus piperacillin-tazobactam as first-line therapy. The two most common second-line therapies in surviving patients were levofloxacin (7%) and amoxicillin (7%); only 2% of deceased patients took levofloxacin and only 1% amoxicillin. Antifungal therapy following sepsis diagnosis was higher in deceased (16%) than in surviving patients (3%).

Conclusions: These results lay bare differences between patients who survive and succumb to sepsis in the US. The apparent low use of blood culture tests indicates that most patients receive empirical antimicrobial treatment. Differences in antimicrobial treatment between deceased and surviving patients may be explained by sepsis cause and severity. Sepsis and death are known to undercoded in EMRs, so results are approximate.

2484 | Comorbidities analysis of patients with atopic dermatitis on non-biologic systemic drug therapy using optum electronic health records databases

Huifang Liang[1], Varinder Singh[2], Dongmu Zhang[1], Jianzhong Liu[1], Philip Sugerman[1], Colleen Wegzyn[1] and Ryan D. Kilpatrick[1]
[1]AbbVie Inc., North Chicago, IL; [2]Syneos Health, Morrisville, NC

Background: Managing comorbid conditions may improve treatment outcomes in patients with atopic dermatitis (AD). Limited data exist on comorbidities in AD patients who are on non-biologic systemic drug therapy.

Objectives: To describe comorbidities in AD patients who are on non-biologic systemic drug therapy.

Methods: A retrospective cohort study was performed to identify patients with AD in the Optum™ Electronic Health Records Databases from 2008-2018 based on the algorithm of Silverberg et al. The algorithm uses two diagnoses of AD, or the combination of (i) one diagnosis of eczema or rash and nonspecific skin eruption and (ii) ≥2 historic codes for asthma, food allergies or allergic rhinitis. Patients were eligible if they were in the integrated data network and had ≥1 year of activity before the index date (or the first date of receiving non-biologic systemic drug therapy after the diagnosis date). Prespecified thirteen comorbidities of interest were assessed using data within one year before the index date. Descriptive statistics were generated for overall and pediatric and adult populations separately.

Results: A total of 286,941 patients were included. Their mean age was 37.1 ± 26.9 years, with children and adults being 34.4% and 65.6%, respectively. Overall, females were predominant (73.3%) among adults; however, males were predominant among children (56.4%). The majority of non-biologic systemic immunosuppressants were corticosteroids (97.6%). The use of the index systemic immunosuppressants was higher in adults than children (3.3% vs 0.64%). Among patients with AD who were on non-biologic systemic drug therapy, over 75% of adults and over 20% of children had at least one comorbidity. More females than males had comorbidities (73.8% vs 63.4%). Asthma was the most common allergic comorbidity in both adults (33.3%) and children (39.1%). Several neuropsychiatric disorders were also common in all patients: sleep disturbances (adults vs children: 20.2% vs 5.2%), anxiety (24.3% vs 2.6%), depression (24.0% vs 1.1%), and attention-deficit/hyperactivity disorder (ADHD) (2.6% vs 4.0% in children). In addition, common non-allergic comorbidities in adults included hypertension 47.2%, hyperlipidemia 42.1%, and diabetes 18.8%.

Conclusions: In patients with AD on non-biologic systemic drug therapy, asthma is the most common allergic comorbidity; common non-allergic comorbidities include sleep disturbances, depression and anxiety. Screening and intervening on atopic and nonatopic comorbidities are essential to alleviating the burden for patients with AD.

2512 | Comorbidities and characteristics in a cohort of patients with NAFLD/NASH from the Netherlands

Jetty A. Overbeek[1], Marieke Krol[2], Kelly Mulder[2], Marina Bakker[1], Ger H. Koek[3] and Ron M.C. Herings[1,4]
[1]PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands; [2]IQVIA, Amsterdam, Netherlands; [3]Maastricht UMC, Maastricht, Netherlands; [4]VU University Medical Center, Amsterdam, Netherlands

Background: The burden of non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) is increasing. However, limited real-world information is available regarding patients with NAFLD/NASH in Europe.

Objectives: To create a dynamic cohort of patients suffering from NAFLD and/or NASH with detailed information to study the safety and effectiveness of future treatment options.

Methods: All patients with a diagnosis of hepatic steatosis in the General Practitioner (GP) Database of the PHARMO Database Network in the period 2009-2018 were selected. The date of first recorded diagnosis was defined as the index date. All patients were followed from index date until end of study period, data availability or death, whichever occurred first. Patients were characterised in terms of demographics, laboratory measurements, comorbidities and medication use.

Results: In total, 9,050 patients were included. Of these patients 54% was male and the mean age (±SD) was 55 (±14) years. The mean (±SD) BMI at index date was 31 (±5) kg/m^2 and 43% was current or former smoker. The median (IQR) ALAT, ASAT and bilirubin value at index date were 51 (33-76) U/l, 35 (26-50) U/l, and 9 (7-12) μmol/L, respectively. The mean (±SD) lipid values at index date were 5.2 ± 1.2 mmol/l (total cholesterol), 3.0 ± 1.0 mmol/l (LDL), 1.2 ± 0.4 mmol/l (HDL), and 2.2 ± 1.5 mmol/l (triglycerides). The most common comorbidities were uncomplicated hypertension (2.9%) and type 2 diabetes (2.7%). In the year before the index date the most frequent reasons for GP visits were general complaints, such as abdominal pain (6%) and weakness/

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tiredness (6%). The most frequently prescribed drugs were omeprazole (26%), diclofenac (16%) and simvastatin (15%).

Conclusions: This study from PHARMO's GP database gave insight in the characteristics of a real-world cohort of NAFLD/NASH patients from the Netherlands. At index the majority of patients were obese and had elevated ALAT levels. Further criteria are needed to distinguish between NAFLD and NASH. This cohort makes it possible to study patients with NAFLD/NASH in a real-world setting.

2518 | Risk of hospitalisation due to infection in patients with psoriasis: A population-based cohort study using the United Kingdom clinical practice research datalink

Zenas Z.N. Yiu[1], Rosa Parisi[1], Mark Lunt[1], Richard B. Warren[1], Christopher E.M. Griffiths[1], Sinéad M. Langan[2] and Darren M. Ashcroft[1]

[1]*University of Manchester, UK, Manchester, United Kingdom;* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: Psoriasis is associated with multiple comorbidities and treated with systemic therapies that may increase the risk of serious infections. The relationship between psoriasis and serious infection, however, is as yet unclear.

Objectives: The primary objective was to determine whether patients with psoriasis have a higher risk of hospitalisation due to infection; the secondary objective was to determine whether patients with psoriasis have a higher risk of death due to infection compared with matched patients without psoriasis from primary care.

Methods: We performed a cohort study of adult patients (≥18 years of age) with psoriasis delineated from the UK Clinical Practice Research Datalink (CPRD GOLD) and linked to Hospital Episode Statistics (HES) and national mortality records between 01/04/2003 and 31/12/2016. Each patient with psoriasis was matched to up to 6 individuals without psoriasis on age, sex, and primary care practice. Hospitalisation due to infection was ascertained in the linked HES records. Unadjusted and adjusted stratified Cox proportional hazard models were estimated, with the adjusted model inclusive of potential confounders such as lifestyle factors and comorbid conditions.

Results: 69,312 patients with psoriasis and 338,598 comparison patients were followed up for a median (inter-quartile range [IQR]) of 4.9 (5.9) and 5.1 (6.3) years respectively. Patients with psoriasis had a higher incidence rate of serious infection (20.5/1000 person-years, 95% CI 20.0-21.0, n=7629) compared with those without psoriasis (16.1/1000 person-years, 95% CI 15.9-16.3, n=30756). The unadjusted hazard ratio for serious infection in patients with psoriasis was 1.46 (95% CI 1.42-1.50), and the fully adjusted hazard ratio was 1.36 (95% CI 1.31-1.40). The unadjusted hazard ratio for death due to infection in patients with psoriasis was 1.30 (95% CI 1.18-1.43), and the fully adjusted hazard ratio was 1.33 (95% CI 1.08-1.63).

Conclusions: Psoriasis is associated with a small increase in the risk of serious infection. Further research is needed to understand the mechanism by which psoriasis predisposes to a higher risk of infection.

2561 | 40-year mortality among patients hospital-diagnosed with overweight or obesity

Sigrid B. Gribsholt[1,2], Dóra K. Farkas[1], Reimar W. Thomsen[1], Bjørn Richelsen[1] and Henrik T. Sørensen[1]

[1]*Aarhus University, Aarhus N, Denmark;* [2]*Aarhus University Hospital, Aarhus N, Denmark*

Background: Obesity is a risk factor for several chronic diseases with an elevated mortality risk compared to the general population. Data on long-term mortality among persons with hospital-diagnosed obesity are limited.

Objectives: To examine 40-year mortality among patients with hospital-diagnosed overweight or obesity.

Methods: We used national registries covering the entire Danish population of 8,846,452 residents and all Danish hospitals between 1979 and 2018. We identified all Danes with a first incident hospital-based overweight or obesity diagnosis (median age 45 years), and constructed an age-, gender-, and index date-matched general population comparison cohort. We computed mortality risk and mortality rate ratios (MRRs) with 95% confidence intervals (CIs), using Cox regression.

Results: We observed 68,506 deaths among 322,130 persons (2,987,320 person years) with a hospital diagnosis of overweight or obesity, and 253,897 deaths among 1,610,596 persons (16,316,670 person years) in the comparison cohort, corresponding to an all-time MRR of 2.02 (95% CI: 2.01-2.04). The mortality risk for patients with overweight or obesity was increased in the first year (2.5% versus 0.4% in comparisons, MRR=6.58 (95% CI: 6.37-6.79)) of follow up. Mortality risk then remained approximately doubled throughout follow-up (1-10y MRR=1.80 (95% CI: 1.78-1.82); 11-20y MRR=1.92 (95% CI: 1.89-1.96); 21-30y MRR=2.05 (95% CI: 2.00-2.11), and 31-40y MRR=2.12 (95% CI: 2.00-2.24)). Patients with overweight or obesity had markedly higher all-time mortality due to diabetes and other endocrine diseases (MRR=4.99 (95% CI: 4.80-5.19)) and cardiovascular diseases (MRR=2.67 (95% CI: 2.63-2.72)), but also due to respiratory diseases (MRR=2.30 (95% CI: 2.24-2.36)), infectious diseases (MRR=1.83 (95% CI: 1.79-1.88), and cancer (MRR=1.48 (95% CI: 1.44-1.53)). The 1-10-year MRR associated with overweight or obesity decreased over calendar time: from 2.02 (95% CI; 1.98-2.06) in 1977-1989 to 1.63 (95% CI; 1.59-1.68) in 2010-2018.

Conclusions: Patients with hospital-diagnosed overweight or obesity had a two-fold increased long-term mortality, compared with the general population. Our data suggest an improved prognosis in patients with overweight or obesity over the last decades.

2569 | Incidence of anemia in patients with chronic kidney disease - A population-based cohort study

Søren V. Vestergaard[1], Uffe Heide-Jørgensen[1], Heleen van Haalen[2], Glen James[3], Katarina Hedman[2], Henrik Birn[4], Reimar W. Thomsen[1] and Christian F. Christiansen[1]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]Aarhus University Hospital, Aarhus, Denmark; [2]AstraZeneca, Gothenburg, Sweden; [3]AstraZeneca, Cambridge, United Kingdom; [4]Aarhus University, Aarhus, Denmark

Background: Anemia is common in patients with advanced chronic kidney disease (CKD) and is associated with increased mortality risk.
Objectives: We conducted a population-based cohort study to clarify the incidence of anemia in patients with newly progressed CKD stages 3-5.
Methods: Using a population-based registry with complete laboratory test results available for the entire population of Northern Denmark (~1.9 million people) during 2009-2016, we identified cohorts of patients with newly progressed CKD (stages 3-5). CKD was defined by two creatinine tests ≥90 days apart both revealing an estimated glomerular filtration rate (eGFR, MDRD) <60 mL/min/1.73 m2. Patients entered a higher CKD stage cohort if their CKD deteriorated during the study period. We followed patients for incident anemia [hemoglobin (Hb) level <12 g/dl in women and <13 g/dl in men] and for incident events of mild (Hb >10 g/dL), moderate (Hb 8-10 g/dL), or severe (Hb <8 g/dL) anemia. We computed cumulative incidence proportions (risks) of anemia by CKD stage, examined anemia trajectories and calculated adjusted hazard ratios (HRs) of anemia by CKD stage, using multivariable Cox regressions with a robust sandwich estimator.
Results: We identified 55,940 individuals with newly progressed CKD in stages 3-5, who over time contributed to CKD stage cohorts [n=41,958 patients in 3a, n=17,875 in 3b, n=5,182 in 4, and n=931 in 5]. Within 1 year 36.1% (95% CI: 35.7 - 36.6) of patients with CKD 3a developed anemia, increasing to 62.3% (95% CI: 61.7 - 62.9) within 5 years. Anemia risks were higher in higher CKD stages, as 80.8% (95% CI: 80.1 - 81.5) of CKD 3b patients, 90.6% (95% CI: 89.6 - 91.5) of CKD 4 patients, and 98.8% (95% CI: 97.8 - 99.4) of CKD 5 patients developed anemia within 5 years. Cox regression showed increases in anemia hazards with increasing CKD stage [adjusted HRs of 1.55 (95% CI: 1.52 - 1.58) in CKD 3b; 2.38 (95% CI: 2.30 - 2.47) in CKD 4; and 5.42 (95% CI: 5.09 - 5.77) in CKD 5, compared to CKD 3a. One in five patients with any CKD stage 3-5, and half of all patients with CKD 5 experienced severe anemia (Hb <8 g/dL) during total 8 years of follow-up.
Conclusions: A substantial proportion of patients with newly progressed CKD develop anemia during the subsequent year, with increasing anemia risk at higher CKD stages. Clinicians should be aware of the high risk of anemia in patients with CKD stage 3-5 in everyday clinical care and exercise vigilance about associated complications.

2610 | Probabilistic linkage of the French cystic fibrosis patient registry with the French national health data system

Manon Belhassen[1], Deborah Walther[1], Lydie Lemonnier[2], Marjorie Bérard[1], Faustine Dalon[1], Isabelle Durieu[3] and Eric Van Ganse[1]
[1]PELyon, Lyon, France; [2]Association Vaincre la Mucoviscidose, Paris, France; [3]HESPER 7425, Health Services and Performance Research, Université Claude Bernard Lyon 1; Centre de Référence Adulte de la Mucoviscidose, Service de Médecine Interne, Hospices Civils de Lyon, Lyon, France

Background: To efficiently assess the management of the cystic fibrosis (CF), the French Cystic Fibrosis Patient Registry was linked to the SNDS (French Claims Data System, with information on health care utilization of the national population).
Objectives: The aim of this linkage was to build a complete dataset that will open up new perspectives of research on CF patients, such as the changes in healthcare consumption, and to relate it to the epidemiological transformation of CF.
Methods: The records of CF patients included between 2006 and 2016 in the French CF Registry were linked by probabilistic method to their corresponding SNDS data. To perform this linkage, a scoring system was developed with variables available in both data sources, ranging from the least (sex, month and year of birth, region of residence) to the most specific ones (dates of spirometry, dates of transplant, and sweat test). Next, a decision algorithm was developed. In a last step, to allocate remaining patients, "comorbidities" (e.g. diabetes, aspergillosis or pancreatic insufficiency) were used. Sensitivity analyses were performed using other scoring systems, to test the validity of the linkage.
Results: Of the 7,671 patients included in the French CF Patient Registry between 2006 and 2016, 6,186 patients (80.6%) could be linked to the SNDS. Non-linked patients were mainly children younger than 10 who had little or no spirometry data. The sensitivity analyses validated the linkage.
Conclusions: We performed one of the first linkages between a French registry and the SNDS. These two data sets include robust and complementary data, leading to an exhaustive database and opening new prospective to study the management of CF patients.

2674 | Characterization of women with adenomyosis identified in a large U.S electronic health record database with and without hysterectomy

Stephanie E. Chiuve[1], Anita M. Loughlin[2], Stacey A. Missmer[3], Michael C. Snabes[1], Keith Gordon[1], Gally Reznor[2], Michael C. Doherty[2] and Cheryl Enger[2]
[1]AbbVie, Inc, North Chicago, IL; [2]Optum, Boston, MA; [3]Michigan State University, Grand Rapids, MI

Background: Adenomyosis is the growth of endometrial tissue into the myometrium. Data on symptoms and comorbidities of adenomyosis have been limited primarily to women diagnosed via uterine histology after a hysterectomy. Although "endometriosis of the uterus" may be used as a surrogate for documentation, emerging hallmarks of adenomyosis do not overlap with endometriosis, and the lack of an ICD code for adenomyosis has limited studies of women living with adenomyosis.
Objectives: To characterize symptoms and comorbidities of women with affirmed adenomyosis, stratified by timing of hysterectomy

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Women aged 18-55 years for whom adenomyosis was mentioned within clinical notes from 2014-2018 were identified using natural language processing of the Optum Electronic Health Record (EHR) database. The anchor date was the date of first affirmed mention of adenomyosis. Covariates were assessed in the 12 months prior to anchor date (baseline period).

Results: Among the 19,503 women with an affirmed mention of adenomyosis, 27% had an ICD code for "endometriosis of the uterus". Among these women, 84% were ≥36 years old, 68% were white, and 45% were obese. In the baseline period, 50% of women had a transvaginal ultrasound, 6% had a pelvic MRI, and 52% had a hysterectomy. Of women who had a hysterectomy, 31% occurred prior to, 56% occurred on and 23% occurred after the anchor date. Gynecologic comorbidities among women without hysterectomy, or women with hysterectomy timed prior to, at, or after anchor date, respectively, were endometriosis (19%, 72%, 32% and 28%), uterine fibroids (18%, 59%, 42% and 26%) and gynecologic cancer (7%, 16%, 10% and 7%). Gynecologic symptoms among women without hysterectomy, or women with hysterectomy timed prior to, at, or after anchor date, respectively, were heavy menstrual bleeding (47%, 78%, 70% and 66%), anemia (19%, 31%, 24% and 21%), pelvic pain (31% 50%, 35% and 42%), dysmenorrhea (18%, 38%, 33% and 30%), and dyspareunia (7%, 14%, 10% and 11%).

Conclusions: While symptoms and comorbidities of adenomyosis may be documented more consistently when diagnosis was made at or after hysterectomy, the ICD code for "endometriosis of the uterus" was documented for <1/3 of women with affirmed adenomyosis, missing 2/3 of diagnosed adenomyosis cases. This suggests that ICD-driven discovery is subject to misclassification and potential selection bias. Natural language processed clinical notes enabled the characterization of women living with adenomyosis that had not been studied previously.

2685 | Applying machine learning to define phenotypes of women with endometriosis undergoing laparoscopic surgery

Andrea K. Chomistek[1,2], Cheryl Enger[1,2], Stacey A. Missmer[3], Stephanie J. Estes[4], Jenna F. Calderbank[1,2], Michael C. Doherty[1,2] and Stephanie E. Chiuve[5]

[1]Optum, Boston, MA; [2]Optum, Ann Arbor, MI; [3]Michigan State University, Grand Rapids, MI; [4]Penn State Health, Hershey, PA; [5]AbbVie, Inc., North Chicago, IL

Background: Endometriosis is an often chronic, inflammatory gynecologic condition; endometriosis-related pain, dysmenorrhea (DYSM), and dyspareunia (DYSP) can impair quality of life. Laparoscopic surgery is used as first-line therapy to remove or ablate endometriosis to relieve pain or performed after failure of medical therapy.

Objectives: To identify phenotypes of women who have had laparoscopic surgery to treat endometriosis defined by patterns of clinical covariates.

Methods: This study was conducted in the Optum Research Database, a claims database from a large U.S. health insurer. Women aged 18-55 years who had a laparoscopic surgery (LS) within the abdomen or pelvic cavity (excluding hysterectomy and oophorectomy), in conjunction with an ICD-10 code for endometriosis within 30 days of surgery, between July 2016 and June 2018 were identified. Machine learning using an agglomerative hierarchical clustering analysis identified subgroups based on comorbidities, procedures, and medications within the 6 months prior to LS and a phenotype was defined for each subgroup based on clinical characteristics.

Results: The cohort included 4,878 women with LS with a mean age of 34 (SD: 8) years. Pain (pelvic, abdominal, lower back) was the most prevalent symptom (81%) and opioid analgesics (52%) and prescription nonsteroidal anti-inflammatory drugs (46%) were the most prevalent medications.

An 8-cluster solution was identified based on cluster statistics and covariate distributions. Among the 8 clusters, one cluster predominantly had endometriosis of the ovary, along with low frequency of pain medication, pain and mental health conditions (6%). Four clusters predominantly had endometriosis of the pelvic peritoneum and the phenotypes identified were: 1) low medication use, DYSM, DYSP, pain comorbidities and mental health conditions (11%); 2) high DYSM and DYSP but low pain medication (14%); 3) infertility and DYSM (5%); and 4) high DYSM, DYSP, pain comorbidities, pain medication, and mental health conditions (11%). Finally, 3 clusters had endometriosis of multiple sites and the phenotypes identified were: 1) high cardiometabolic comorbidities and pain medication use, but low DYSM and DYSP (11%); 2) high DYSM, DYSP, pain comorbidities, pain medication and poor mental health (21%); and 3) heavy menstrual bleeding and leiomyoma (21%).

Conclusions: Among patients with endometriosis who underwent laparoscopic surgery, we identified several phenotypes based on varying patterns of clinical covariates. Future studies might consider whether unmet needs for surgical avoidance differ by patient phenotype.

3695 | Occurrence of metabolic risk factors stratified by psoriasis severity: A Swedish population-based matched cohort study

David Hägg[1], Marie Linder[1], Mohammadhossein Hajiebrahimi[1], Ci Song[2], Therese M.-L. Andersson[3] and Reginald Villacorta[4]

[1]Karolinska Institutet, Centre for Pharmacoepidemiology, Stockholm, Sweden; [2]Janssen-Cilag, Stockholm, Sweden; [3]Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden; [4]Janssen Research & Development, LLC, Horsham, PA

Background: Psoriasis is a chronic immune-mediated inflammatory disease which can affect up to 8% of the population in Nordic countries. Patients with psoriasis experience an increased risk of developing metabolic risk factors such as diabetes mellitus (DM), hypertension (HTN) or hypercholesterolemia. Understanding whether patients with psoriasis are being actively managed regarding metabolic risk factors is a research gap in the literature. Based on prior work that demonstrated an increased risk of HTN and DM among Swedish

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients with severe psoriasis during a one-year period before anti-psoriasis drug prescription, the current study aims to understand the time to occurrence of metabolic risk factors such as DM, HTN and hypercholesterolemia.

Objectives: To assess relative risk of metabolic risk factors in patients stratified by psoriasis severity compared with population controls.

Methods: Retrospective cohort study conducted using national Swedish registers. Adult patients with psoriasis were selected if they had a dispensing of anti-psoriasis prescription (2007-2013) and at least one diagnosis within 5 years before the dispensing date. The patients with psoriasis were matched 1:10 to controls from the general population on birthyear, sex and county. The cohort was further divided into three disease severity groups (mild, moderate or severe) based on their dispensed anti-psoriasis medication. We applied flexible parametric modelling to understand the risks of the incident comorbidities HTN, hypercholesterolemia and DM among patients with psoriasis from 6 months through 10 years. Hazard ratios and predicted risk of comorbidities are reported.

Results: The hazard of HTN, hypercholesterolemia and DM is higher among psoriasis patients compared with population controls, and the hazard ratio increased following the psoriasis severity. For example, HRs of HTN for patients with mild, moderate and severe psoriasis are 1.29 (95% CI: 1.27-1.32), 1.35 (95% CI: 1.32-1.38) and 1.73 (95% CI: 1.64-1.82), respectively. The predicted risk of HTN, hypercholesterolemia, and DM among patients with severe psoriasis at year ten was 0.58 (95% CI: 0.56, 0.59), and 0.22 (95% CI: 0.21, 0.24) respectively while it was 0.42 (95% CI: 0.41, 0.43), 0.30 (95% CI: 0.30, 0.30), 0.11 (95% CI: 0.10, 0.11) among controls, respectively. The predicted risk at year ten was similar among patients with mild or moderate psoriasis.

Conclusions: The HRs and the predicted risks of metabolic risk factors are higher among patient with psoriasis compared with matched controls, and more prominent among the severe psoriasis group.

3722 | Identifying adenomyosis and undiagnosed adenomyosis within natural language processed clinical notes of an electronic health record database

Anita M. Loughlin[1], Gally Reznor[1], Michael Doherty[1], Stacey A. Missmer[2], Stephanie E. Chiuve[3] and Cheryl Enger[4]
[1]*Optum, Boston, MA;* [2]*Michigan State University, Grand Rapids, MI;* [3]*AbbVie Inc., North Chicago, IL;* [4]*Optum, Ann Arbor, MI*

Background: Often diagnosed at hysterectomy, adenomyosis is the presence of endometrial tissue within the myometrium. The prevalence of identified adenomyosis is low (0.17%) due to diagnostic challenges and lack of a specific ICD code.

Objectives: To identify women with adenomyosis using NLP data in the Optum EHR database and to estimate the prevalence of potentially undiagnosed adenomyosis (PUA).

Methods: Adenomyosis cases were identified from a population of 11,456,347 women aged 18-55 years with NLP data in the EHR (2014-2018). Adenomyosis mentions were scored by applying a rank to sentiments (-1 to +2) and modifiers (-2 to +1); range of total possible scores was +3 to -3. An affirmed adenomyosis mention had a score of +2 or +3. The anchor date was set at the date of first affirmed adenomyosis mention. Baseline characteristics were assessed in the 12 months prior to the anchor date. Characteristics common to adenomyosis cases were used to select a suitable pool from the underlying population among whom undiagnosed adenomyosis might exist. Adenomyosis cases were compared to a sample of the suitable pool (comparators) using logistic regression, and we determined the predictive probability (PP) of being an adenomyosis case. The proportion of the comparators having a PP > 0.1 was considered PUA; 75% of adenomyosis cases and 7% of comparators had PP > 0.1. We extrapolated the proportion of PUA in the comparators to calculate the prevalence of PUA in the underlying population.

Results: There were 19,503 women with affirmed adenomyosis. Of the 332,583 comparators, we identified 22,696 women with PUA. The PUA prevalence estimate was 19.1 per 1,000 women aged 18-55 years. The majority of women with adenomyosis and PUA, respectively, were aged 36-55 years (84%, 86%) and white (69%, 66%). The frequency of transvaginal ultrasound, pelvic MRI, and hysterectomy, respectively, was 50%, 6%, and 16% in adenomyosis cases and 46%, 5% and 5% in PUA cases. Women with adenomyosis and PUA, respectively, had similar frequency of heavy bleeding (60%, 60%), pelvic pain (36%, 36%) and dysmenorrhea (26%, 22%). Gynecologic comorbidities appeared higher in adenomyosis cases relative to PUA: endometriosis (31%, 11%) and uterine fibroids (31%, 25%).

Conclusions: Using NLP and considering PUA, the prevalence of adenomyosis may be up to 10x higher than prior estimates. Identification of adenomyosis in real world data may improve disease characterization and assessment of treatment effectiveness. Increased diagnostic suspicion and early detection may facilitate better management among symptomatic women.

3735 | Treatment, healthcare resource utilization, and healthcare costs for medicare patients with generalized pustular psoriasis and palmoplantar pustulosis

Allison A. Petrilla, Sudeepti Pahuja, Shambhavi Kumar and Courtney R. Jaeger
Avalere Health, Washington, DC

Background: Generalized Pustular Psoriasis (GPP) and Palmoplantar Pustulosis (PPP) are rare and severe distinct disease entities from plaque psoriasis; however, the burden of illness for these patients is unknown.

Objectives: To characterize treatment patterns, healthcare utilization (HCRU) and costs for a cohort of GPP and PPP patients in the US Medicare Fee-for-Service population.

Methods: GPP and PPP patients were identified by ≥ 1 inpatient or ≥ 2 outpatient diagnoses (at least 30 days apart) in a 100% sample of Medicare FFS beneficiaries between January 1, 2016 and December

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

31, 2017. Patients were required to have ≥ 6 months of continuous medical and pharmacy coverage prior to the date of diagnosis (baseline period) and ≥ 12 months of the same continuous coverage following the diagnosis (follow-up period). Demographics, comorbidities, and treatment patterns were captured during the baseline period. Treatment patterns, all cause HCRU, and total direct healthcare costs were measured during the follow-up period in 6-month increments using descriptive statistics.

Results: 1,818 GPP and 1,968 PPP patients were identified. GPP and PPP patients were primarily Caucasian (GPP: 86%; PPP: 85%) and female (GPP: 74%; PPP: 66%) with a mean age of 68 at index diagnosis. 39.4% of GPP and 34.2% of PPP patients originally qualified for Medicare benefits due to disability rather than age. Hyperlipidemia (GPP: 90%; PPP: 87%), Type 2 Diabetes Mellitus (GPP: 56%; PPP: 46%), and other psoriasis conditions (GPP: 54%; PPP: 41%) were the most common comorbidities. Patients with GPP and PPP were mostly treated with steroids or biologics; adalimumab was the most commonly used biologic. At 12-month follow-up, mean counts of hospitalizations, ER visits, and outpatient visits were (GPP: 2.0; PPP: 1.6), (GPP: 2.4; PPP: 2.0), and (GPP: 41.6; PPP: 36.1), respectively. Median costs for GPP and PPP patients were (GPP: $4,205.10; PPP: $2,954.71) at baseline, (GPP: $5,253.20; PPP: $3,294.35) at 6 months, and (GPP: $10,646.87; PPP: $7,005.84) at 12 months of follow-up.

Conclusions: Medicare beneficiaries with GPP and PPP frequently treated with steroids and biologics incur high costs associated with HCRU. Future research should examine long term HCRU and economic burden across different payer types.

3741 | The spectrum of adenomyosis identified in a large US electronic health record database

Anita M. Loughlin[1], Gally Reznor[1], Michael Doherty[1], Stephanie E. Chiuve[2] and Cheryl Enger[3]

[1]Optum, Boston, MA; [2]AbbVie Inc, North Chicago, IL; [3]Optum, Ann Arbor, MI

Background: Adenomyosis, the presence of endometrial tissue within the myometrium, can co-exist conditions such as endometriosis and leiomyomas that have symptoms in common; thus it is difficult to delineate of symptom profiles specific to adenomyosis. Until recently, a definitive diagnosis was made by hysterectomy, recently use of MRI and transvaginal ultrasound allow for non-surgical diagnosis.

Objectives: To examine the spectrum of the clinical presentation of adenomyosis.

Methods: Characteristics of women aged 18-55 years, with an affirmed mention of adenomyosis, identified in the natural language processed clinical notes of the Optum EHR database (2014-2018) were assessed. An anchor date was set as date of first qualifying adenomyosis mention. Baseline characteristics were identified in the 12 months prior to anchor date. A predictive probability (PP) model compared adenomyosis cases to a sample of symptomatic women aged 18-55 years without an affirmed adenomyosis mention. Adenomyosis cases were stratified by PP, and baseline characteristics were assessed across strata.

Results: 19,503 women with adenomyosis were stratified from highest to lowest PP, specifically, 3,336 (PP, ≥ 0.9); 3,651 (PP, 0.6-0.8); 3,523 (PP, 0.3-0.5); 3,857 (PP, 0.1-0.2); and 5,136 (PP, <0.1). Women in the highest PP strata were proportionally more likely to be 35+ years of age (93%, 90%, 88%, 83%, and 71%) and to have been pregnant (74%, 65%, 64%, 56%, and 32%), relative to women in the lowest PP strata. Likewise, women in the highest PP strata were more symptomatic–heavy menstrual bleeding (HMB) (87%, 78%, 74%, 56%, and 23%), pelvic pain (52%, 44%, 39%, 33%, and 22%), dysmenorrhea (46%, 36%, 29%, 19%, and 10%), and gastrointestinal (GI) symptoms (51%, 47%, 44%, 41%, and 38%). General symptoms were predominant symptoms among women in lowest PP stratum, i.e., abdomen/ lower back pain (41%) and GI (38%), while the prevailing symptoms in women in higher PP strata were HMB (87%) and pelvic pain (52%). Women in the highest PP strata had more gynecologic comorbidities–endometriosis (93%, 47%, 18%, 10% and 5%), leiomyomas (57%, 46%, 34%, 22%, and 8%), uterine polyps (13%, 8%, 5%, 4%, and 1%) and hysterectomy (51%, 23%, 11%, 5%, and 2%), relative to those in the lower PP strata.

Conclusions: Using PP stratification of the cases, we show that the adenomyosis clinical presentation can ranged from mildly symptomatic to severely symptomatic, making recognition of disease and management of adenomyosis often difficult. Understanding symptom profiles may improve diagnostic suspicion, early detection, and lead to more treatment options for women with adenomyosis.

3742 | Dopamine agonists and risk of lung cancer

Maria P. Hernandez-Con[1], Justine Shults[1,2], Allison Willis[1] and Yu-Xiao Yang[1]

[1]University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Pennsylvania, Philadelphia, PA

Background: There is a clinical need to identify novel chemopreventive and therapeutic targets for lung cancer because it remains the leading cause of cancer deaths worldwide despite newer treatment options. Preclinical evidence suggests that dopamine receptor activation induces apoptosis and inhibits cancer cell proliferation in lung cancer. Dopamine agonists (DAs) are commonly used in Parkinson's disease (PD) and restless leg syndrome (RLS).

Objectives: To determine the association between long-term DA use and the risk of lung cancer.

Methods: We conducted a population-based retrospective cohort study using private insurance administrative claims data from Optum®ClinformaticsTMData Mart (1/2006 - 12/2016). The study population included all adults ≥ 40 years who had ≥ 1 outpatient or inpatient ICD-9 or ICD-10 diagnosis for RLS recorded during the study period. We excluded PD patients because PD itself is associated with a lower overall risk of cancer. Cohort follow-up started on the date of first RLS diagnosis and ended on the earliest of the following: incident diagnosis of lung cancer, end of enrollment in the database or

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

end of study period. The exposure of interest was cumulative duration (i.e., no use or ≤1 year [reference group], 1- 3 years and > 3 years) of DA (i.e., pramipexole, ropinirole or rotigotine) use, measured in a time-varying manner. The outcome was time to incident lung cancer. We constructed a multivariable Cox regression model to estimate the HRs and 95% CIs for lung cancer associated with cumulative durations of dopamine agonist use. The model was adjusted for the following covariates: age, gender, race/ethnicity, area of residence, chronic obstructive pulmonary disease (COPD), tobacco use and interstitial lung disease (ILD).

Results: Over the 11-year study period, we identified 303,079 eligible patients with a diagnosis of RLS. The mean age of the study population was 62.9; 66.3% were women and 82.3% were white. The prevalence of any DA exposure in the study population was 48.2%. Compared to the reference exposure group, the crude HRs for lung cancer were 1.16 (95%CI 1.03 -1.3) and1.33 (95% CI 1.09 -1.62) for 1-3 years and > 3 years of cumulative DA use, respectively. In multivariable Cox regression analysis, the adjusted HR for lung cancer was 1.00 (95% CI 0.89-1.13) for 1-3 years of cumulative DA use and 1.09 (95% CI 0.89-1.34) for > 3 years of cumulative DA use.

Conclusions: At doses typical for the clinical management of RLS, long-term DA use was not associated with the risk of lung cancer. Future studies are needed to determine whether there is a clinically apparent anti-cancer effect of DA exposure at higher doses as those used in animal experiments.

3834 | 21-year trends in first hospitalization for acute urinary retention and subsequent mortality in the Danish male population: A nationwide cohort study

Maria B. Bengtsen[1], Uffe Heide-Joergensen[1], Michael Borre[2] and Mette Nørgaard[1]

[1]*Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus N, Denmark*; [2]*Department of Urology, Aarhus University Hospital, Aarhus N, Denmark*

Background: Acute urinary retention (AUR) is a severe complication to benign prostatic hyperplasia associated with high mortality among men in all ages. Limited data exist on trends in incidence and mortality after hospitalization for AUR after the introduction of medical therapy for benign prostatic hyperplasia in the mid 1990's.

Objectives: To investigate trends in AUR incidence and mortality after the introduction of medical therapy for benign prostatic hyperplasia.

Methods: We conducted a nationwide registry-based study in Denmark of all men aged above 50 years with a first hospital (inpatient, outpatient or emergency room) diagnosis of AUR between 1997 and 2017. We used the Danish National Patient Registry and the Danish National Prescription Registry to compute baseline characteristics and proportion of men who redeemed prescription of drugs associated with AUR within 90 days before AUR diagnosis. We computed the standardized incidence rate and the standardized 3-month and 1-year mortality rate after first diagnosis of AUR. Using the Kaplan Meier method, we estimated mortality overall and according to age and Charlson Comorbidity Index (CCI) Score.

Results: We identified 77,047 men above 50 years with a first hospital diagnosis of AUR. The median age was 76 (interquartile range: 68-83) years and 54 % had moderate to severe comorbidity (CCI score ≥1). At time of first AUR diagnosis, about half (49 %) had previous benign prostatic hyperplasia/lower urinary tract symptoms; 11 % had urogenital cancer; 16 % had diabetes and 12 % had chronic pulmonary disease. Within 90 days before AUR diagnosis, 18 % had redeemed a prescription for opioids, 17 % benzodiazepines and 19 % antipsychotics. The standardized incidence rate increased with 30 % during 1997-2017; from 3.1 (95 % CI: 3.0-3.2) per 1000 person-years in 1997 to 4.0 (95 % CI: 3.9-4.7) in 2017. The increase in incidence occurred during 1997-2004, and then remained stable during 2005-2017. The 3-month standardized mortality rate decreased from 10.9 % (95 % CI: 9.5-12.2) in 1997 to 7.9 % (95 % CI: 7.0-8.7) in 2017, and 1-year mortality from 23.7 % (95 % CI: 21.7-25.7) in 1997 to 18.1 (95 % CI: 16.8-19.4) in 2017.

Conclusions: The standardized incidence rate of AUR has increased with 30 % since the introduction of medical therapy, but has remained stable since 2005. Despite a slight decrease in mortality, men hospitalized for AUR remains to have a high mortality.

3837 | Prevalence of contraindication in chronic kidney disease according to eCrCl and eGFR equations and patient related risk factors

Susanne Stolpe and Cornelia Blume

Institute of Technical Chemistry, Leibniz University, Hannover, Germany

Background: Contraindicated (CI) medications in patients with chronic kidney disease (=CKD, glomerular filtration rate (GFR) <60ml/min) negatively impact patients health outcomes. Drug safety information for medications is derived from analyses of kidney function using creatinine clearance (CrCl), in diagnosis, prognosis and treatment of CKD equations normalized on body surface are used to estimate GFR (eGFR).

Objectives: To estimate prevalence of CI medication in non-institutionalized CKD patients using CrCl and eGFR equations and to identify patient groups at higher risk for CI

Methods: We analysed information of 13.338 patients (aged 18-99 years) using baseline data collected in 2010 from the German ",Kern-database." The database comprises patients from five German cohort studies and registries dealing with CKD and related comorbidities (GCKD, 4C, CADRef, DiabCore, BIS). Potential CI medications were identified using PRISCUS-list, BEERS list, START/STOPP-criteria and from literature. eGFR-was calculated with CKD-Epi and the Modification of Diet in Renal Disease (MDRD) equation, CrCl was estimated using the Cockcroft-Gault equation (CG). Prevalence of CKD and of CI was estimated with these equations.

Results: Prevalence of CKD differed by equation: 34% [95%CI: 33%-35%] using CG, 47% [46%-47%] with CKD-Epi and even 49% [48%-

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

50%] with MDRD. Prevalence of CKD4+ (=eGFR <30ml/min) was 2.2% [1.9%-2.4%] with CG, 5.2% [4.8%-5.5%] using CKD-Epi and 5.4% [5.0-5.8] with MDRD equation. Number of drugs taken increased with CKD -stage, but not with age.

Proportion of CI was about 3.4% in CKD3 using any equation. In CKD4, proportion of CI was distinctly higher and depending on GFR equation used: 38% [35%-42%] (MDRD), 41% [37%-44%] (CKD-Epi), and 45% [39%-51%] with CG. Risk for CI increased with number of drugs taken and with risk of kidney failure -calculated with the Kidney-failure-risk-equation. Women (RR=1.3 [1.1-1.5]) and patients unaware of their disease (CKD3: 1.3 [0.9-1.8], CKD4: RR 1.8 [1.5-2.2]) were at higher risk for CI medication. Most CI medications were anti-hypertensive or anti-diabetic drugs. CIs identified by CG only concerned patients in higher ages, relating to hydrochlorothiazide.

Conclusions: The variety of equations for estimating renal function limits comparability of prevalence information for CKD. Precise identification of CIs is aggravated. CI medication is highly prevalent in CKD4 patients. Especial attention to prevent CI medication should be given to female CKD-patients and to patients with polymedication and at higher risk for kidney failure.

3920 | Participant engagement in an arthritispower real-world study to capture smartwatch and patient-reported outcome data among rheumatoid arthritis patients

Jeffrey R. Curtis[1], W. Benjamin Nowell[2], Fenglong Xie[1], Hong Zhao[1], David Curtis[2], Kelly Gavigan[2], Shilpa Venkatachalam[2], Laura Stradford[2], Jessica Boles[2], Justin K. Owensby[1], Cassie Clinton[1], Ilya Lipkovich[3], Amy Calvin[3] and Virginia S. Haynes[3]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Global Healthy Living Foundation, Upper Nyack, NY; [3]Eli Lilly and Company, Indianapolis, IN

Background: Clear characterization of how different types of patient-generated data reflect patient experience is needed to guide integration of electronic patient-reported outcome (ePRO) measures and biometrics in generating real-word evidence (RWE) related to rheumatoid arthritis (RA).

Objectives: To characterize the level of participant (pt) engagement/adherence and data completeness in an ongoing study of 250 RA pts enrolled in the Digital Tracking of Arthritis Longitudinally (DIGITAL) study of the ArthritisPower (AP) real-world registry.

Methods: AP pts with RA joined a digital RWE study with 14-day lead-in and 12-week main study period. Pts who completed the lead-in received a smartwatch (Fitbit Versa) and study materials. The smartwatch collected activity, heart rate, and sleep duration/quality biosensor data; a study-specific customization of the AP mobile application collected ePROs. The main study period included automated and manual reminders/prompts to complete ePROs, wear the smartwatch, and sync regularly. Study coordinators monitored pt data and contacted pts via email, text and/or phone to resolve adherence issues based on pre-determined rules triggering pt contact. Pts were considered adherent if providing (1) daily ePROs for ≥5 of 7 days/week, (2) weekly ePROs and (3) ≥80% of synced activity data for ≥5 of 7 days/week.

Results: As of December 2019, 170 AP members had enrolled and completed at least 30 days of the main study period; 92.9% female with mean (SD) age 52.5 (10.7) and 10.5 (10.4) years since diagnosis. The overall conversion rate from initial interest to successful completion of the lead-in period was 49.0%. Pts who advanced to the main study were significantly more likely to be employed (52.9%) and on a biologic DMARD monotherapy (64.7%). Overall, daily ePRO data had the lowest adherence (70.0% of pts providing >70% of requested data) across the first 30 days of the study period. Composite adherence was met by 66.5% of pts. Activity data had the highest adherence and persistence, with 92.9% of pts providing 80% or more of activity data for each 24-hour period in the first 30 days. Observed weekly adherence did not decline over time.

Conclusions: RWE studies involving passive data collection in RA require pt-centric implementation and design to minimize pt burden, promote longitudinal engagement, and maximize adherence. Passive data capture via activity trackers such as smartwatches, along with regular contact such as automated reminders, may facilitate greater pt adherence in providing longitudinal data for clinical trials.

3985 | Incidence of opioid abuse, dependence, and overdose in osteoarthritis patients prescribed opioids in the United States - A retrospective cohort study

Xiaofeng Zhou[1], Qing Liu[1], Rongjun Shen[1], Charles Wentworth[1], Richard Gong[1] and Leo Russo[2]

[1]Pfizer Inc., NYC, NY; [2]Pfizer Inc., Collegeville, PA

Background: Osteoarthritis (OA) is a common joint disorder and a leading cause of pain and disability among adults, especially the elderly. Prescription opioids are one treatment option, with another being NSAIDs/COX 2 inhibitors. Although opioid addiction is a known concern, few studies have investigated the incidence of opioid abuse, dependence (OAD) and overdose in OA patients.

Objectives: To estimate the incidence rates (IRs) of 3 endpoints among OA patients with moderate to severe pain who were prescription opioid naive:1) OAD from any medical setting; 2) opioid overdose during a hospitalization or emergency department visit (i.e. in facility); and 3) opioid overdose linked with death in facility

Methods: A retrospective cohort study using 2006-2018 OPTUM claims data was conducted. Adult patients (≥18 years) diagnosed with OA who had used at least 2 different non-opioid analgesic medications (as proxy measure for moderate to severe OA pain) in the 24 months of continuous enrollment prior to the index date, and met study inclusion/exclusion criteria, were included. OA was defined by ICD-9/10-CM codes. Drugs were defined by NDC and procedure drug codes. Index date was the dispensing date of the first opioid prescription. IRs and 95% confidence interval (CI) of the 3 endpoints were calculated.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 81,909 OA patients with moderate to severe pain who were opioid naïve were identified. The majority of patients were female (63%), aged 65 years and older (54%), and had a history of hypertension (69%). IRs per 1,000 PY for OAD from all settings, opioid overdose in facility, and opioid overdoses linked with in‐facility death were 3.37 [95%CI: 3.13, 3.62], 1.66 [95%CI: 1.49, 1.84], and 0.10 [95%CI: 0.06, 0.15] respectively. Older patients (65+ years) had higher IRs per 1000 PY compared to those aged 18-<65 years: 3.88 [95% CI: 3.55, 4.23] vs. 2.61 [95%CI: 2.30, 2.98] for OAD from all settings; 2.20 [95%CI: 1.96, 2.47] vs. 0.86 [95%CI: 0.68, 1.07] for opioid overdose in-facility; and 0.15 [95%CI: 0.10, 0.24] vs. 0.01 [95%CI: 0.00, 0.08] for opioid overdoses associated with in‐facility death.

Conclusions: Using a large US Claims database, we estimated the real-world IRs of medically diagnosed OAD and overdose among OA patients with moderate to severe pain who were prescription opioid naïve. The risk of opioid addiction appears to be higher among those aged 65 and above. These data in OA patients were not previously available in the medical research literature. Future analyses may benefit from confounder adjustment, medical chart review, and estimation using other databases.

3989 | Potential utility of a novel aggregated US electronic medical record database: Renal transplant pilot

Rachel E. Sobel[1], Robert J. Taylor[2], Stacey N. Purinton[2] and Aaron Berger[3]

[1]United Biosource Corp (UBC), Blue Bell, PA; [2]Cerner Corporation, Kansas City, MO; [3]United Biosource Corp (UBC), Kansas City, MO

Background: Electronic medical records (EMR) have many advantages over typical insurance claims data, such as lab tests, vital signs, and information captured during clinical care. Use of EMR data for rare diseases, exposures, or outcomes has been hampered by multiple proprietary EMR systems that historically lack continuity, resulting in small sample sizes. We sought to identify a rare outcome, renal transplant (RT), in a large novel aggregated US EMR system to describe clinical and population characteristics.

Objectives: To conduct a feasibility pilot to describe the proportion of RT patients with select lab tests, diagnoses, and medications by examining a national US EMR database (DB).

Methods: A retrospective cohort study was conducted using Cerner Real World Data (CRWD), a national de-identified research DB that aggregates Cerner and other EMR systems; data were analyzed with the Cerner "*HealtheDataLab*" tool. The DB contains healthcare data from 80M pts with 652M encounters from >46 health systems.

Patients were identified using first relevant procedure code for RT (CPT, ICD10 PCS, ICD9 CM, MEDCIN, SNOMED CT, NCI, or Read Code) during the study period (01Jan15-31Dec19). Cohort was analyzed for the proportion of patients with lab test orders and/or results for renal function ([RFs]; eg., BUN, eGFR), urinary protein, electrolytes, comorbidities, and outcomes such as dyslipidemia, opportunistic infections, and transplant rejection, as defined by appropriate LOINC procedure codes, ICD10 diagnostic codes, and NDC or DNUM codes for immunosuppressant drugs.

Results: Of >30.3M individuals in the DB during the study period, there were 1302 patients with RT (0.004%; 56.4% male; mean age=48.7 y, range 2-81 y; mean time since RT=1040 d). Post-RT, 1.5% had a subsequent transplant rejection diagnosis, 10.2% had cardiac disease, 9.2% had anemia, and 0.9% had opportunistic infection; 52.7% had record of immunosuppressant medication use. During the entire study period (pre and post RT), 86.6% of patients had >=1 RF test (n=186,603 tests, or 143.3 RFs/pt). Testing frequency ranged from 23 tests/pt (urinary protein) to 504 entries/pt (blood pressure [BP]). Of these tests, electronic results' availability ranged from 95.6% for RFs to 99.9% (BP, serum calcium, phosphorus).

Conclusions: While additional work is needed to better understand the data and explore the comparability of this RT population to existing statistics, this pilot suggests over the 5-yr study period, there may be adequate sample sizes, longitudinality, and key clinical data in this aggregated EMR DB to study certain rare diseases and outcomes such as RT.

4095 | Using self-reported outcomes to detect new-onset flare in a real-world study of participants with rheumatoid arthritis - Interim results from the digital tracking of arthritis longitudinally (DIGITAL) study

Jeffrey R. Curtis[1], Virginia S. Haynes[2], Fenglong Xie[1], Ilya Lipkovich[2], Hong Zhao[1], Carol Kannowski[2], Jiat L. Poon[2], Kelly Gavigan[3], David Curtis[3], Sandra Nolot[1] and W. Benjamin Nowell[3]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Eli Lilly and Company, Indianapolis, IN; [3]Global Healthy Living Foundation, Upper Nyack, NY

Background: Patients with rheumatoid arthritis (RA) experience fluctuating symptoms between visits to clinicians. Digital Tracking of Arthritis Longitudinally (DIGITAL) study is evaluating electronically captured patient-reported outcomes (ePRO) and passive data collection from a Fitbit device to identify disease worsening in a real-world study participants (pts) with RA.

Objectives: Evaluate agreement between self-reported new-onset flare and ePROs in an interim analysis from DIGITAL using a classification model.

Methods: Members of the ArthritisPower (AP) registry with RA participated in DIGITAL. Pts who completed the lead-in wore a smartwatch, and provided daily and weekly ePROs, including OMERACT RA Flare Questionnaire (FLARE) and PROMIS measures. A "Yes" response to the FLARE question identified a flare. For modeling association between new-onset flare and ePRO, we split the dataset into training (first 30 days) and test data (Day 31+). Repeated binary outcomes (Flare/No Flare) per pt were defined each week. To focus on new-onset flare, we excluded outcomes for patient weeks in which flare was present in previous week. Candidate variables for the model included baseline and current FLARE score (0-50 scale) and each of its

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

5 items, daily pain, daily fatigue, and several PROMIS weekly instruments and their lagged values (last week or last 6 days for daily). 'Baseline' was calculated in non-flare weeks. Training data was used for logistic regression model selection combining clinical expertise with backward elimination. Performance of the final model was evaluated using test data.

Results: The training data was composed of outcomes from 128 pts who reported 388 weekly flare. Of pts in the training dataset, 92.2% were female, 87.5% white, mean age (SD) 52.7 (11.0), and years since RA diagnosis 10.4 (10.3); 62.5% were on a biologic. Among those in the training dataset, 58 flare outcomes occurred in 50 (39.1%) unique pts. The best-performing model in training data included the current and baseline FLARE question, current daily pain, and baseline daily pain average and standard deviation. In test data, this model had an area under the receiver operator curve of 0.81. At a cut point requiring specificity to be ≥0.80, sensitivity to detect flare was 0.62 and overall accuracy was 0.78.

Conclusions: Evaluation of passive data as proxy for self-reported new-onset flare is ongoing using machine learning methods

4105 | Two machines are better than one: Using multi-agent reinforcement in machine learning to simulate a clinical second opinion

Cao Xiao[1], Junyi Gao[1], Lucas Glass[2], Jimeng Sun[3] and Christina Mack[4]
[1]IQVIA, Cambridge, MA; [2]IQVIA, Plymouth Meeting, PA; [3]UIUC, Champaign, IL; [4]IQVIA, Durham, NC

Background: When it comes to patient health, a second opinion is often a wise and needed choice. Accurate diagnoses and appropriate treatment selection based on patient risk can be difficult, especially for complex or rare diseases. Multi-agent reinforcement learning is a novel sub-field within machine learning and has shown great success in the realm of Markov Decision Problems (MDPs) including medical decision making.

Objectives: Simulate the practice of seeking a second opinion for diagnosis, prognosis and risk of morbidity and mortality by training 2 reinforcement learning (RL) agents using a different focus for each: a) the primary agent ("first doctor"), which studies the most recent visit of the patient to learn the current health status; b) a "second-opinion" agent, which considers the entire patient history to obtain a more global view.

Methods: Two RL agents were trained on electronic health records (EHR) within the Medical Information Mart for Intensive Care database (2001-12) to simulate second-opinion situation using a) patient's current health condition and b) summary of the patient's historical data. Performance was compared against clinical predictive models across 4 clinical tasks: (1) In-hospital mortality prediction, (2) Acute care phenotype classification, (3) Physiologic Decompensation prediction, (4) Forecasted length of hospital stay. Knowledge of disease progression was provided via long-term reward function; the model was further customized with patient demographics. Dynamic skip-connection was used to focus on relevant information over time, while baseline models made current-time medical decisions based only on last-visit information (Markovian assumption).

Results: Multi-agent reinforcement consistently outperformed models using only a single agent across all 4 clinical outcomes and medical tasks for all metrics. Specifically, it achieved 16% higher area under the precision-recall curve (AUPRC) and 15% lower mean squared error (MSE) and mean absolute percentage error (MAPE) than the best-performing baseline model (SAnD; Simply Attend and Diagnose) and was also superior to a time-aware LSTM model.

Conclusions: Multi-agent reinforcement learning is a cutting edge ML approach that, while typically used in video game environments, is highly applicable to the complex setting of diagnoses and healthcare decision making. The two-agent machine was able to model long-term dependencies of patients' health status while considering patients' demographics and achieve better prediction performance across clinical prediction tasks.

4106 | Agreement between administrative database and medical chart review for the prediction of chronic kidney disease stage

Sylvie Perreault[1], Louise Roy[1], Michael Zappitelli[2], Brian White-Guay[1], Jean-Philippe Lafrance[1] and Marc Dorais[3]
[1]University of Montreal, Montreal, QC, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Statsciences Inc, Montreal, QC, Canada

Background: Chronic kidney disease (CKD) is a major health issue. Validity assessment of administrative data for the detection of CKD in research on drug benefit and risk using real-world data is important.

Objectives: To validate a CKD predictive algorithm using the administrative databases of Quebec compared to medical chart review as a reference standard in patients with estimated glomerular filtration rate (eGFR).

Methods: Study design: Three administrative databases from RAMQ database and Quebec Health Ministry Database were linked and provided information on demographics and clinical characteristics for 434 patients with normal and abnormal kidney function. **Setting:** All patients 23 years and older received follow-up care in one of these clinics, with at least two serum creatinine measures (up to 1 year apart) between 2013 and 2015. Medical file data were collected by trained nurses in 3 community medical centers in Quebec. We collected the administrative records of hospitalization and medical services in the 5-year period prior to the cohort entry, and the pharmaceutical files in the 2-year period prior to cohort entry. Algorithms were developed to measure eGFR using administrative data. **Main outcome:** We estimated eGFR using the CKD Epidemiological Collaboration, using retrospectively collected variables including variables like age, sex, and serum creatinine measurement. **Statistical:** To estimate the sensitivity, specificity, positive predictive, and negative predictive values of diagnosis code of CKD, medication used, and medical visits for nephrology using administrative databases. Validity

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

indices were estimated for each case definition combination using laboratory data as the reference standard.

Results: The validity of eGFR < 30 mL/min/1.73m^2 was assessed with sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). Sensitivity ranged from 82.5% to 99.4%. Specificity ranged from 76.1% to 98.9% with PPV and NPV ranging from 69.5% to 97.7% and 91.1% to 99.5%, respectively. The subsequent validation with literature data and different cohorts of patients emphasized the accurate prediction of the proportion of patients with eGFR < 30 mL/min/1.73m^2.

Conclusions: The case definition of eGFR < 30 mL/min/1.73m^2 derived from an algorithm using diagnosis code, drug use, and nephrologist visits from administrative databases seems to be a valid algorithm compared to medical chart reviews for older adults with CKD.

4125 | Real world evidence of graft survival in four types of transplants: Fifteen years analysis in Brazil

Ludmila P. Gargano[1,2], Túlio T.R. Sarmento[2], Natália C.C. Freitas[1], Guilherme F. Nascimento[1], Rosângela M. Gomes[1], Lucas L. Torres[2], Carolina M.F. Ferreira[2], Carolina Z. Dias[1,2], Isabella F. Zuppo[1,2], Francisco A. Acúrcio[1,2], Juliana Álvares-Teodoro[1,2] and Augusto A. Guerra[1,2]

[1]*Postgraduate Program in Medicines and Pharmaceutical Assistance - Faculty of Pharmacy - UFMG, Belo Horizonte, Brazil;* [2]*SUS Collaborating Centre Technology Assessment and Excellence in Health, Belo Horizonte, Brazil*

Background: Transplantation could be an alternative to increase the patient survival and improve their quality of life. In Brazil, the National Health System (SUS) is responsible for almost 96% of all transplants made in the country. The SUS is a universal, integral, equalitarian and free system of health care. Immunosuppressive treatment is dispensed to transplanted patients on a monthly basis.

Objectives: To assess graft survival in kidney (TxK), liver (TxL), heart (TxH), and lung (TxP) transplantation performed by SUS from 2000 to 2015.

Methods: Cohort study using linkage of 3 SUS administrative databases through deterministic-probabilistic matching: the Hospital Information System (SIH), the Outpatient Information System (SIA), and the Information System of Mortality (SIM). Patients who have undergone kidney, liver, heart or lung transplantation in SUS between January 1, 2000 to December 31, 2014 were included. The survival analysis (SA) was performed using the Kaplan-Meier estimator to determine the cumulative graft survival probability of patients from all four types of transplant. The event considered was graft loss or death.

Results: A total of 63,316 patients were included. 75.6% of patients were submitted to TxK, 20.1% to TxL, 3.5% to TxH and 0.9% to TxP. The SA indicates that the survival rate at the end of the first year was 91.1% (95%IC 90.9 - 91.4%) for TxK, 72.6% (95%CI 71.8%-73.4%) for TxL, 71.1% (69.2%-73.1%) for TxH, and 75.7% (95%CI 71.9%-79.6%) for TxP. At the end of the 15th year of follow-up, the survival rate decreased to 40.9% (95%CI 39.3%-42.6%) for TxK, 45.2% (95%CI 42.2%-48.5%) for TxL, 30.5% (25.2%-37.0%) for TxH, and 20.3% (95%CI 10.4%-39.6%) for TxP. The median survival was 143 months for TxK, 145 months for TxL, 103 months for TxH. and 63 months for TxP.

Conclusions: This research shows an overview of different transplants performed by the Brazilian National Health System and provides information that could support studies of comparative effectiveness of immunosuppressive treatment. Also, this database focused on the individual will allow researchers to perform other clinical, epidemiological and economic studies, in addition to allowing better decision-making for the Brazilian Health System.

4136 | Weight gain following antiretroviral therapy (ART) initiation in ART-naive participants in the current treatment era

Stephanie Ruderman[1], Heidi Crane[1], Robin Nance[1], Bridget Whitney[1], Barbara Harding[1], Kenneth Mayer[2], Richard Moore[3], Joseph Eron[4], William Mathews[5], Benigno Rodriguez[6], Michael Saag[7], Amanda Willig[7], Sara Lindstrom[1], Brian Wood[1], Ann Collier[1], Greer Burkholder[7], Mari Kitahata[1] and Joseph Delaney[8]

[1]*University of Washington, Seattle, WA;* [2]*Harvard Medical School, Fenway Institute, Boston, MA;* [3]*Johns Hopkins, Baltimore, MD;* [4]*University of North Carolina, Chapel Hill, NC;* [5]*University of California San Diego, San Diego, CA;* [6]*Case Western University, Cleveland, OH;* [7]*University of Alabama Birmingham, Birmingham, AL;* [8]*University of Manitoba, Winnipeg, MB, Canada*

Background: People living with HIV (PLWH) who initiate integrase inhibitor (INSTI)-based antiretroviral therapy (ART) may increase body weight more quickly than those initiating other ART regimens.

Objectives: We evaluated weight change among PLWH initiating ART in the current treatment era.

Methods: Between 2012-2019, across 8 Centers for AIDS Research Network of Integrated Clinical Systems (CNICS) sites, we identified 3156 ART-naïve PLWH initiating ART, including efavirenz (EFV), rilpivirine (RPV), atazanavir (ATV), darunavir (DRV), raltegravir (RAL), elvitegravir (EVG), dolutegravir (DTG), or bictegravir (BIC), with tenofovir disoproxil fumarate (TDF), tenofovir alafenamide fumarate (TAF) or abacavir (ABC) and emtricitabine or lamivudine (standard 3+ drug combination regimens for initial ART). Weight change was examined during all follow-up time on regimen (excluded newer regimens with limited mean follow-up e.g., containing TAF) and short-term (6 month; including all regimens) using linear mixed models adjusted for time on regimen, interaction between time and regimen, age, sex, race, hepatitis B or C coinfection, nadir CD4, smoking, diabetes, antipsychotic medication use, and site.

Results: Mean follow-up on initial ART regimen was 1.8 years. In analyses including all follow-up, compared with EFV/TDF, DTG/ABC was associated with a 0.8 kg (95%CI:0.4-1.1) per 6-months greater weight gain while DTG/TDF was associated with a 0.6 kg (95%CI:0.1-1.2) per

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

6-months greater weight gain. Other INSTI-based regimens showed less weight gain. Weight gain on DTG/ABC was greater than EFV/TDF, RPV/TDF, and EVG/TDF, but not DRV/TDF (1.1 kg per 6-months, 95%CI:0.5-1.6). In short-term (6 month) analyses, compared with EFV/TDF, BIC/TAF (5.0 kg (95%CI:2.5-7.4)) and DTG/TAF (4.9 kg (95%CI:2.2-7.6)) were associated with the greatest weight gain per 6 months, followed by DRV/TDF (4.1 kg (95%CI:2.3-5.9)) and DTG/TDF (3.1 kg (95%CI:1.5-4.7)).

Conclusions: DTG users showed greater weight gain than RAL or EVG users, although differences decreased with longer follow-up. DRV/TDF users showed the greatest weight gain in the long-term, while DTG/TAF- and BIC/TAF-based regimens showed the greatest gain in the first 6 months. For ART-naïve PLWH, potential weight gain should be considered in conjunction with the benefits of viral suppression when comparing ART regimens.

4142 | Defining phenotypes of women with endometriosis undergoing hysterectomy or oophorectomy using machine learning

Andrea K. Chomistek[1,2], Cheryl Enger[1,2], Stacey A. Missmer[3], Stephanie J. Estes[4], Jenna F. Calderbank[1,2], Michael C. Doherty[1,2] and Stephanie E. Chiuve[5]

[1]Optum, Boston, MA; [2]Optum, Ann Arbor, MI; [3]Michigan State University, Grand Rapids, MI; [4]Penn State Health, Hershey, PA; [5]AbbVie, Inc., North Chicago, IL

Background: Endometriosis is an often chronic and painful, inflammatory gynecological disorder. Current treatment for management of pelvic pain includes medical therapies and surgery. If medical treatment and conservative surgery have been ineffective, a hysterectomy (with or without oophorectomy) is considered when childbearing is complete.

Objectives: To identify phenotypes of women with endometriosis who have had a hysterectomy or bilateral oophorectomy based on clinical covariates.

Methods: This study was conducted in the Optum Research Database, a claims database from a large U.S. health insurer. Women aged 18-55 years with a hysterectomy or bilateral oophorectomy (HYBO), combined with an ICD-10 code for endometriosis within 30 days of surgery, between July 2016 and June 2018 were identified. Machine learning using an agglomerative hierarchical clustering analysis was performed to identify subgroups of patients among those with HYBO based on clinical characteristics documented within the 6 months prior to surgery. A phenotype for each subgroup was defined by patterns of comorbidities, procedures, and medications.

Results: The cohort included 7,005 women with HYBO with mean age 44 (SD: 6) years. Sixty-three percent of women had pain in the pelvis, abdomen, or lower back, while 38% and 11% had dysmenorrhea and dyspareunia, respectively. Frequently used medications included opioid analgesics (53%) and prescription nonsteroidal anti-inflammatory drugs (47%). An 8-cluster solution was identified based on cluster statistics and covariate distributions; 4 clusters were characterized by high frequency of uterine fibroids (UF) (≥70%), 3 by moderate UF (60-70%), and one by low UF (<40%). The 4 clusters with high UF were defined as: 1) low pain (22%); 2) low pain but poor mental health (7%); 3) high pain medication use (11%); and 4) high endometriosis-related pain, pain comorbidities, digestive and cardiometabolic disorders (15%). The 3 clusters with moderate UF were defined as: 1) high endometriosis-related pain but low pain medication use (11%); 2) high pain comorbidities and pain medication use (10%); and 3) endometriosis outside the uterus (i.e. ovary, fallopian tubes, pelvic peritoneum) (12%). The final cluster was defined by low UF, high endometriosis-related pain, pain comorbidities, pain medication use, and prior laparoscopic surgery (13%).

Conclusions: Among patients with endometriosis who underwent HYBO, we identified several phenotypes based on patterns of clinical covariates. Future studies might consider whether unmet needs for surgical avoidance differ by patient phenotype.

4225 | Incidence of community-acquired pneumonia in China: A nationwide claims database analysis

Yixin Sun[1], Yinchu Cheng[2] and Siyan Zhan[1]

[1]Peking University, Beijing, China; [2]Peking University Third Hospital, Beijing, China

Background: Community-acquired pneumonia (CAP) is one of the major global health problems and among the top 10 causes of death worldwide. However, the epidemiological information of CAP is limited in China.

Objectives: To estimate the incidence rate of CAP and describe the epidemiologic characteristics among Chinese population.

Methods: We conducted a retrospective analysis on CAP incidence using the Chinese Urban Basic Medical Insurance database of 23 provinces in 2016, which covered 427·52 million urban beneficiaries of all age groups in Mainland China. CAP episodes were identified using diagnosis-term-derived algorithm, and multiple CAP records of one single person within 90 continuous days were considered as one single episode. The incidence rates were calculated and described by sex, age, region, and season.

Results: A total of 1·42 million patients were identified as having one or more CAP episodes, and finally a sum of 1·48 million CAP episodes were counted. The overall incidence of CAP was 7·13 (95% CI: 6·11-8·15) per 1000 person-years, in males 7·32 (95% CI: 6·28-8·35) and females 6·93 (95% CI: 5·92-7·94) per 1000 person-years, respectively. The incidence varied by age with a U-shaped curve peaking in children aged < 5 years old [65·80 (95% CI: 62·52-69·08)] and elderly population aged ≥ 80 years old [14·98 (95% CI: 13·63-16·34)]. The incidence varied markedly by regions. Furthermore, the rate showed a clear seasonal trend, which peaked in spring, decreased in summer and autumn, and re-ascended in winter.

Conclusions: This study reveals a relatively high level of CAP incidence in China. These findings provide baseline data for establishing effective prevention strategies, targeted at susceptible population, regions and seasons in China.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4266 | Changes in serum creatinine values during and after pregnancy in a cohort of women with or without pre-existing chronic kidney disease

Carole Marxer[1,2], Katrina W. Hagberg[3], Rishi J. Desai[4,5], Julie M. Paik[4,5], Susan S. Jick[3,6], Christoph R. Meier[1,2,3] and Julia Spoendlin[1,2]

[1]University Hospital Basel, Basel, Switzerland; [2]University of Basel, Basel, Switzerland; [3]Boston Collaborative Drug Surveillance Program, Lexington, MA; [4]Brigham and Women's Hospital, Boston, MA; [5]Harvard Medical School, Boston, MA; [6]Boston University School of Public Health, Boston, MA

Background: Chronic kidney disease (CKD) occurs in up to 3% of women of childbearing age. Impaired kidneys may not sufficiently adapt to physiological changes during pregnancy, which may result in accelerated CKD progression.

Objectives: To describe changes in renal filtration during/after pregnancy in women with or without CKD.

Methods: We performed a longitudinal descriptive study using data from the UK-based Clinical Practice Research Datalink (2000-2018). We included pregnancies ending in live birth if they had ≥ 1 serum creatinine (SCr) value recorded during a 1-year baseline period before the estimated last menstrual period or during trimester 1. Pregnancies were categorized into 3 groups based on the mean estimated glomerular filtration rate (eGFR [ml/min/1.73m^2], CKD-EPI formula) during baseline/trimester 1: no CKD (eGFR ≥ 90), mild CKD (eGFR 60-90), moderate-severe CKD (GFR < 60). We captured demographics and risk factors for CKD and calculated percentage changes of mean SCr levels (group means) as a proxy for renal filtration in 3-month intervals during and until 1 year after pregnancy. We quantified the difference between the mean baseline eGFR and mean eGFR 6-12 months after delivery.

Results: Of 169'855 pregnancies, maternal moderate-severe CKD was present in 981 (0.6%), mild CKD in 29'433 (17.3%), and no CKD in 139'441 (82.1%) pregnancies. Pre-existing hypertension, diabetes, and/or obesity was recorded in 37% in moderate-severe CKD, and in 30% in the other 2 groups. Autoimmune diseases pre-existed in 3-4% in all groups. Mean reduction in SCr levels were larger between baseline and the end of trimester 2 in women without CKD (-22%) and with mild CKD (-24%) than in women with moderate-severe CKD (-14%). Thereafter, mean SCr levels increased, to level off around 6 months after delivery. In women without CKD, mean eGFR levels 6-12 months after delivery (118 ml/min, SD 15) were comparable to baseline SCr levels (119 ml/min, SD 13). Women with mild CKD revealed an increased eGFR (97 ml/min, SD 18) after delivery (baseline eGFR 88 ml/min, SD 9). In women with moderate-severe CKD, the post-pregnancy eGFR (55 ml/min, SD 23) was similar to the baseline eGFR (50 ml/min, SD 14), but sample size was small (incomplete lab data).

Conclusions: Our results suggest that kidneys of women with moderate-severe CKD adapted to a lesser degree to physiological changes during pregnancy, but sample size was small. Renal filtration was not decreased within 1 year after delivery in all groups. The increased post-pregnancy eGFR in women with mild CKD may reflect continued hyperfiltration or random variability.

4274 | Utilising mobile and web-based technology for capturing patient specific information: Methods from the DISCOVER CKD program

Glen James[1], Juan Jesus Carrero[2], Jenny Wei[3], Gary Curhan[4], Eric Wittbrodt[5], Steven Fishbane[6], Carol Moreno Quinn[1], Hiddo Heerspink[7], Katarina Hedman[8], Eiichiro Kanda[9], Tony Chen[5], Naoki Kashihara[9], Björn Holmqvist[8], Mikhail Kosiborod[10], Peter Fenici[1], Mitja Lainscak[11], Jennie Medin[8], Carolyn Lam[12,13], Roberto Pecoits-Filho[14,15], Carol Pollock[16], Peter Stenvinkel[17] and David Wheeler[18]

[1]AstraZeneca, Cambridge, United Kingdom; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Shanghai, China; [4]Harvard Medical School, Boston, MA; [5]AstraZeneca, Gaithersburg, MD; [6]Northwell, New York, NY; [7]University of Groningen, Groningen, Netherlands; [8]AstraZeneca, Gothenburg, Sweden; [9]Kawasaki Medical School, Okayama, Japan; [10]University of Missouri-Kansas City, Kansas City, MO; [11]University of Ljubljana, Ljubljana, Slovenia; [12]National Heart Centre, Singapore, Singapore; [13]Duke NUS, Singapore, Singapore; [14]Pontifícia Universidade Católica do Paraná, Parana, Brazil; [15]Arbor Research, Ann Arbor, MI; [16]University of Sydney, Sydney, Australia; [17]Karolinska Institutet, Stockholm, Sweden; [18]University College London, London, United Kingdom

Background: Chronic kidney disease (CKD) is a global health problem associated with cardiovascular complications, impaired health-related quality of life (HRQoL) and high mortality. New ways of capturing patient experiences and burden of disease in settings outside of the clinic through mobile or web-based technology are becoming more widely used, but not within CKD real-world data.

Objectives: Utilising mobile and web-based technology to capture patient specific information.

Methods: DISCOVER CKD is an enriched hybrid observational study utilising a novel cloud-based IT platform to integrate retrospective and prospective data from patients with estimated glomerular filtration rate (eGFR) less than 75 ml/min/1.73 m^2 through to end stage kidney disease from the UK, US, Italy, Sweden, China and Japan. Prospective data will be captured over a 3-year period from >1,000 CKD patients. Data collected by validated instruments including HRQoL (SF-36), physical activity (RAPA), work productivity (WPAI), diet (food diary), and other patient-reported outcomes will be captured in a bespoke mobile/web-based application to be completed by the patient before, during or after their routine clinical visit. The application will be available, validated and user-tested in multiple languages.

Results: Capturing patient-reported information outside of the clinic setting provides an innovative patient-centric approach for understanding the burden and journey of CKD from a patients' perspective. Initial results are anticipated later in 2020.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Utilising mobile/web-based technology to collect patient experiences has the potential to increase the understanding of a disease, with easier communication, minimising burden of data collection in the clinic from a patient, physician and eCRF perspective while improving the consistency and validity of data that patients enter.

4377 | Population trends in the 10-year prevalence and incidence of psoriasis and psoriatic arthritis in Taiwan: A nationwide, population-based cohort study

Ireny Y.K. Iskandar[1], Teng-Chou Chen[1], Li-Chia Chen[1], Meng-Sui Lee[2], K. Arnold Chan[3], Christopher E.M. Griffiths[4] and Darren M. Ashcroft[1]

[1]Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optmetry, University of Manchester, Manchester, United Kingdom; [2]Department of Dermatology, National Yang-Ming University, Taipei, Taiwan; [3]Health Data Research Center, National Taiwan University, Taipei, Taiwan; [4]NIHR Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom

Background: The burden of psoriasis and psoriatic arthritis across many world regions is high, but there is limited information on the incidence and prevalence of these long-term diseases from Asian countries.

Objectives: To estimate the prevalence and incidence of psoriasis and psoriatic arthritis on the basis of age and gender, and to explore temporal trends in their epidemiology in Taiwan over a 10-year period.

Methods: Population-based cohort study using the Taiwan National Health Insurance claims records, which covered 99.9% of Taiwan's population between 2006 and 2017. The International Classification of Diseases, 9th and 10th edition diagnosis codes were used to identify patients with ≥1 diagnostic code for psoriasis or psoriatic arthritis with the diagnosis made by either a dermatologist or rheumatologist. A sensitivity analysis using ≥2 diagnostic codes made by any medical speciality was also conducted.

Results: The overall prevalence (per 100,000 population) for psoriasis and/or psoriatic arthritis increased steadily from 0.19% (194 cases per 100,000) in 2006 to 0.94% (936 cases per 100,000) in 2017. Specifically, the prevalence increased from 0.18% (180 cases per 100,000) to 0.86% (855 cases per 100,000) for psoriasis; and from 0.01% (8 cases per 100,000) to 0.08% (77 cases per 100,000) for psoriatic arthritis. The incidence rates for psoriasis and/or psoriatic arthritis, however, remained stable over time. Overall, the prevalence and incidence of psoriasis were higher in males compared to females. However, the prevalence and incidence rates for psoriatic arthritis were found to be similar between the genders. The incidence data showed a clear bimodal age pattern in psoriasis onset, with the first and second peak at around 30-39 and 70-79 years of age, respectively, characteristic of early-onset and late-onset psoriasis. The prevalence data showed an increasing trend with age until around 90 years of age, after which it decreased. Results from the sensitivity analyses were consistent with the main findings.

Conclusions: The steady increase in the prevalence of psoriasis and psoriatic arthritis over the last decade has important implications for healthcare service delivery and for resource allocation. This increase in the prevalence which does not appear to be attributable to increasing incidence rates, suggests that improvements in life expectancy are likely to be the key determinant to this increase.

4390 | Assessing comorbid inflammatory arthritis conditions and swollen to tender joint count ratios in a real world systemic lupus erythematosus cohort

Cristi Cavanaugh, Greg Donadio, Kathryn Starzyk, Kathleen Mortimer, Michael Behling, Gary Curhan and Rich Gliklich

OM1, Inc., Boston, MA

Background: Joint swelling and tenderness are common in patients with systemic lupus erythematosus (SLE) and other inflammatory arthritis conditions such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Swollen to tender 28-joint count ratio (STR) is an index proposed in RA to assess joint involvement with a higher score indicating greater likelihood of treatment response. Given the prevalence of joint involvement in SLE, STR has potential application in this patient population.

Objectives: To assess the overlap of SLE and other inflammatory arthritis conditions in a real-world cohort and characterize patients based on joint involvement, as defined by STR.

Methods: The OM1 SLE Registry (OM1, Boston, MA) follows more than 37,000 SLE patients longitudinally with deep clinical data, including laboratory, patient-reported and disease activity information, and linked administrative claims starting from 2013. Patients with swollen and tender 28-joint counts assessed at the same encounter were included. Patient cohorts were defined as SLE+ (RA, PsA or AS) vs. SLE alone. STRs were calculated by inserting 1 if the denominator was 0. Patients were categorized as low (STR <0.5), moderate (0.5 ≤ STR ≤ 1.0) or high (STR >1.0), based on first observed STR. Clinical characteristics were summarized by cohort and STR group.

Results: The study included 9,919 patients (92.1% female) with ≥1 STR available in the OM1 SLE Registry. Of the 17.0% of patients in the SLE+ cohort, 94.8% had RA, 6.7% PsA and 1.6% AS. SLE+ patients were older at 57.1 years (standard deviation [SD]: 13.1) compared to 51.1 (SD:14.9) for SLE alone. Comorbid osteoarthritis was more common in the SLE+ cohort (46.3% vs. 26.0%). The SLE+ cohort also had higher STRs: low (69.3%), moderate (19.3%), high (11.4%) compared to 82.6%, 10.8% and 6.7%, respectively, in the SLE cohort. For SLE+, immunosuppressant use increased with higher STR from 44.5% (low STR) to 54.2% (high STR). For SLE alone, immunosuppressant use was lower overall (26.5%) with similar use among STR groups. Select disease-modifying antirheumatic drug (DMARD) use was higher among SLE+ patients (33.9% vs. 3.9%) with highest use in the moderate STR group (39.2%). Use of belimumab or rituximab was higher

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

among SLE+ (13.7% vs. 7.5%) with highest use in the low STR group (14.3%).

Conclusions: Higher STR and differences in treatment patterns were observed in the SLE+ cohort. Additional research is needed to assess the relationship between STR and treatment response in SLE and relevant subphenotypes.

4413 | Description of COPD patients treated with multiple inhaler triple therapies (MITT) using the CPRD GOLD and CPRD aurum electronic health record (EHR) databases

Gema Requena[1], Leah Sansbury[2], Achim Wolf[3], Rachael Williams[3], Jennifer Quint[4], Daniel Dedman[3] and Jeanne M. Pimenta[1]
[1]*GlaxoSmithKline, London, United Kingdom;* [2]*GlaxoSmithKline, Collegeville, PA;* [3]*Medicines and Healthcare Products Regulatory Agency, London, United Kingdom;* [4]*Imperial College, London, United Kingdom*

Background: The Clinical Practice Research Datalink (CPRD) GOLD has been previously used for observational respiratory research however, limited research has additionally used CPRD Aurum. To better understand this new database, we aim to compare key clinical variables related to COPD patients in the CPRD Aurum with the CPRD GOLD database. Recent guidelines (*GOLD 2019*) recommend the use of MITT in COPD patients and we used this population as an example to assess differences.

Objectives: Identify and describe COPD patients treated with MITT in CPRD GOLD and CPRD Aurum to assess whether patients and data differ between databases.

Methods: Patients with a GP recorded COPD diagnosis, aged ≥35 years, registered for ≥1 year and receiving MITT prescriptions continuously for at least 3 months at index date (December 31, 2017) were included. Patient characteristics were described at index, disease severity and healthcare resource use (HCRU) were described 1-year prior index date and comorbidities at any time in the patient's history.

Results: 3,600 COPD patients in CPRD GOLD and 8,981 in CPRD Aurum were treated with MITT at index. Patients characteristics were comparable across CPRD GOLD and CPRD Aurum respectively: median age (70, 71 years), proportions male (55, 54%), most deprived (52, 58%) and overweight/obese (59, 63%). Current smoking was more prevalent in CPRD Aurum (37, 47%). Proportions of patients with a history of asthma (59, 57%), "severe/very severe airway limitation" (35, 41%), median FEV1/FVC (57, 60), and moderate COPD exacerbations, mean (2.0, 1.6 per person-year) were comparable. However, pneumonia (12, 21%) and mMRC scores 3-5 (47, 66%), were higher in CPRD Aurum. Other comorbidities were similar across databases. In terms of HCRU, the number of all-cause hospitalisations was higher in CPRD Aurum (mean 1.0, 2.1); GP visits were similar; and nurse visits were higher in CPRD GOLD (mean 4.5, 2.4).

Conclusions: Patients and data from the two databases were comparable across key aspects of a COPD population. When interpreting results from both databases, researchers should consider the impact of differences in geographical distribution of practices, and the completeness of recording for specific variables. CPRD Aurum significantly increased the patient pool, illustrating suitability for respiratory research and potentially utility to investigate uncommon events.

4417 | Enhancing model interpretability and accuracy for disease progression prediction via phenotype-based patient similarity learning

Christina Mack[1], Yue Wang[2], Fan Zhang[3], Corey M. Benedum[4], Yunlong Wang[2] and Emily Zhao[2]
[1]*IQVIA, Durham, NC;* [2]*IQVIA, Plymouth Meeting, PA;* [3]*IQVIA, Plymouth, NC;* [4]*IQVIA, Cambridge, MA*

Background: Recent growth of longitudinal claims data has enabled the use of machine learning (ML) to help clinicians find undiagnosed patients and understand what clinical factors are related to specific diseases. This information is often used to examine market share or support trial enrollment, but the real patient impact in the clinical setting remains unrealized. Enabling ML to move beyond finding predictors (identifying variables correlated with a disease or outcome) to making predictions (predicting the diagnosis of patients with an outcome of interest) will bring the value of ML to the patient. One challenge is that clinicians remain skeptical of models they do not fully understand. Non-negative matrix factorization (NMF), an ML approach that emphasizes interpretability, can address this gap by creating informative model predictors by grouping patients into *phenotypes* based on clinical data. Phenotype membership is defined by patterns in observed factors; allowing the end-user to observe factors relevant to each phenotype.

Objectives: Using a clinical setting of chronic lymphocytic leukemia (CLL), develop ML models incorporating NMF. Evaluate the ability to enhance model interpretability and accuracy, enabling greater utility for clinicians.

Methods: We used NMF to group patients according to frequently observed claims codes. Clinical experts described each phenotype to understand commonalities between the most frequently observed clinical codes. We then developed ML models to predict the diagnosis of CLL. Model predictors included demographic and clinical service predictors, and with or without phenotype predictors. We used Precision-Recall and Area Under the Curve (PR-AUC) and F1 score to assess model accuracy.

Results: NMF clustered patients into 3 phenotypes, defined by codes related to: 1) respiratory disease and pain, 2) blood related clinical services/anemia, 3) infections. Inclusion of phenotype predictors increased CLL prediction for each tested model by an average of 2 percentage points for PR-AUC. All models which included phenotype predictors generally had higher F1 scores.

Conclusions: These results suggest that inclusion of phenotype predictors enhanced each model's interpretability and accuracy of CLL predictions. NMF extracts more detail from claims data, enabling the model to attain highly explanatory predictors indicative of the targeted disease. We envision that clinical phenotypes can be used to

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

improve model interpretability and accuracy for rare disease detection or pairing patients with well-matched clinicians and medications.

4420 | The incidence of acute pancreatitis in the United States: Identification of cases in an electronic healthcare database with supportive laboratory evidence

Usha Gungabissoon[1], Megan Delgado[2], Selin Cooper[3], Liyuan Ma[4] and Iain Uings[3]
[1]GSK, London, United Kingdom; [2]University of North Carolina, Chapel Hill, NC; [3]GSK, Stevenage, United Kingdom; [4]GSK, Philadelphia, PA

Background: Despite acute pancreatitis (AP) being one of the most common causes of gastrointestinal disease hospitalizations in the United States (US), few robust US epidemiological studies exist to quantify its incidence. Most published estimates in the US are higher than reported elsewhere, whether this reflects a true difference remains unclear. A diagnosis of AP is made on the basis on clinical symptoms and laboratory evidence. In most studies, there is a lack confirmatory evidence from laboratory testing or imaging meaning that individuals with clinically suspected AP whose diagnosis is subsequently ruled could be included, thus overestimating the incidence of AP.
Objectives: To estimate the incidence of AP using an ICD code alone, to compare with published estimates, or in combination with laboratory evidence to obtain a more accurate estimate of incidence.
Methods: Data from the Cerner Corporation's Health Facts® (HF) electronic health record database were used to identify AP cases in 2015. Cases were classified as "possible AP" or "probable AP" based on the presence of an ICD code alone or in combination with laboratory evidence, respectively. Possible AP was defined as an inpatient or emergency admission with the presence of an ICD code for AP in the primary position. Probable AP was defined as the presence of an ICD code for AP in any position and laboratory evidence (defined as amylase and/or lipase values three times the upper limit of normal) during the hospital admission. The incidence of AP (per 100,000 population) was estimated using two denominators; the study population and nationally inflated estimates to the 2015 United States population.
Results: Of the 4,684,825 individuals with at least one encounter in 2015, a total of 8,833 individuals had an AP ICD code at any position. Of these, 5,732 (64.9%) and 3,739 (42.3%) met the criteria for possible AP and probable AP, respectively. Across AP definitions (probable and possible AP), sex, age, and etiology were comparable. Using the study population as the denominator, the incidence of possible and probable AP was 122.4 (95% Confidence Interval [CI]: 119.2, 125.5) and 79.8 (95% CI: 77.2, 82.4) per 100,000 population, respectively. Inflation to national estimates yielded lower incidence estimates of 46.5 (95% CI: 46.3, 46.8) and 29.4 (95% CI: 29.2, 29.6), respectively.
Conclusions: Our results indicate that AP could be less common in the US than previously reported. Estimates of incidence from our study are similar to those reported using a similar approach in Europe.

4439 | Incidence of acute pancreatitis among US adolescents and adults diagnosed with atopic dermatitis, asthma, or chronic rhinosinusitis with nasal polyposis, 2014-2018

Andrea F. Marcus[1], Cherise Wong[1], Sarah-Jo Sinnott[2], Anna Coleman[1], Faisal Khokhar[1], John D. Huber[1], David Lederer[1] and Steve Gao[1]
[1]Regeneron Pharmaceuticals, Tarrytown, NY; [2]Sanofi, Cambridge, MA

Background: The incidence of acute pancreatitis (AP) among individuals with type-2 inflammatory diseases is not well documented.
Objectives: To estimate the incidence of AP among individuals with a diagnosis of atopic dermatitis (AD), asthma, or chronic rhinosinusitis with nasal polyposis (CRSwNP), stratified by age.
Methods: The study period for this retrospective cohort study spanned January 1, 2014 - September 30, 2018. Three cohorts were identified from Truven MarketScan data and defined as individuals aged ≥12 years with diagnosis codes as follows: 1) AD (ICD-9 code: 691.8/ ICD-10 codes: L20.0, L20.81, L20.82, L20.84, L20.89, L20.9), 2) asthma (at least one inpatient or at least 2 outpatient diagnosis codes for asthma (ICD-9: 493.xx/ICD-10: J45.*), or 3) CRSwNP (at least one inpatient or at least 2 outpatient diagnosis codes for nasal polyps (ICD-9: 471.*/ICD-10: J33.*). The index date was defined as the first date of AD, asthma, or CRSwNP diagnosis. The outcome was defined as the presence of one inpatient diagnosis code for AP (ICD-9: 577.0/ICD-10: K85.9*). Patients with an AP diagnosis on the index date or within the past 3 months of it were excluded. Incidence rates (IRs) were calculated by dividing the number of AP diagnoses by total number of person-years (PY= AP diagnosis or end of study minus the index date).
Results: Overall, the AD cohort included n=85,051 individuals, the asthma cohort n=995,055, and the CRSwNP cohort n= 34,929. In all three cohorts, a large proportion of individuals were >40 years old (ranging from 50.7-74.0%). There were more females in the AD (62.4%) and asthma (65.3%) cohorts than males, but less females in the CRSwNP cohort (40.7%). The crude IRs (per 10,000 PY) for AP were 7.6 (95% CI: 6.4, 9.1) in the AD cohort, 14.2 (13.7, 14.7) for the asthma cohort, and 8.5 (6.6,11.0) for the CRSwNP cohort. IRs increased with age for AD (ages 12-17 years=1.17; 18-39=4.25; 40 +=12.15 per 10,000 PY) and asthma (ages 12-17=3.16; 18-39=10.06; 40+=17.79 per 10,000 PY), but not CRSwNP (ages 12-17=8.38; 18-39=4.21; 40+=9.64 per 10,000 PY).
Conclusions: Our findings indicate that AP occurs among populations with AD, asthma, or CRSwNP, and that age-adjusted AP rates increased with age for AD and asthma, but not CRSwNP. The crude IRs for the AD and CRSwNP cohort are comparable to unadjusted rates of AP in the general population, however, the asthma cohort IR was substantially higher. Further study evaluating risk factors associated with AP development is needed.

4442 | Stigma as a barrier to the hepatitis C virus continuum of care in the era of direct-acting antiviral therapies

M. Elle Saine[1,2], Julia E. Szymczak[1], Frances K. Barg[1] and Vincent Lo Re, III[1]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]Perleman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA

Background: The number of patients with Hepatitis C virus (HCV) infection has tripled in the past decade. Despite highly curative all-oral direct-acting antiviral therapies, most patients remain undiagnosed, are not linked into care, and do not receive antiviral treatment. Stigma is an important and understudied barrier to HCV treatment and elimination, but the extent to which stigma interferes with HCV diagnosis, linkage to care, and treatment initiation remains unknown.

Objectives: We conducted an exploratory mixed-methods study evaluating the impact of stigma at each step along the HCV Continuum of Care, a healthcare framework for identifying gaps in HCV diagnosis (Step 1), linkage to care (Step 2), treatment (Step 3), and antiviral adherence/cure (Step 4).

Methods: We conducted cross-sectional surveys among HCV-infected patients in Philadelphia, PA, USA using the HCV-stigma scale, a validated 33-item questionnaire that measures HCV-related stigma. Qualitative data were collected via a free-response question within the survey instrument and semi-structured interviews among a purposive subsample of 22 participants who completed the survey instrument. Associations between HCV-related stigma and stage of treatment were evaluated by multivariable linear regression. Survey responses were linked to narrative data on patient's lived experiences with HCV at each stage of care.

Results: Among 265 participants, the median stigma score was 75.57 (SD, 19.13). Although scores did not differ significantly between each step along the HCV Care Continuum (P=0.204), most participants (95.5%) experienced some degree of HCV-related stigma. Experiences of HCV-related stigma posed barriers to each of the steps along the Continuum of Care: 1) Diagnosis: injection drug use history interfered with HCV testing; 2) Linkage to Care/Treatment: stigma from healthcare providers, particularly refusal of services, was a barrier to linkage to care and antiviral treatment initiation; 3) Antiviral Adherence/Cure: experiences of social distancing, being treated as "dirty" for having HCV, and reluctance to disclose diagnosis to family/friends adversely affected antiviral adherence and cure.

Conclusions: Participants described HCV-related stigma as an important barrier in access to care. Importantly, stigma from healthcare providers creates significant barriers to medical care and antiviral treatment among patients with HCV. Addressing HCV-related stigma may increase HCV diagnosis, linkage to care, and treatment uptake and improve health-related quality of life.

4444 | Prevalence, mortality, disease progression and associated comorbidities of chronic obstructive pulmonary disease in the United States: A literature review

Anil Dasari[1], Salman Hussain[2] and Pradeep Basa[3]
[1]Independent Researcher, Delhi, India; [2]Jamia Hamdard, Hamdard University, Delhi, India; [3]Independent Researcher, Bangalore, India

Background: Chronic Obstructive Pulmonary Disease (COPD) is the major component of chronic lower respiratory diseases and characterized by obstruction to airflow that interferes with normal breathing. COPD is the fourth leading cause of death in the United States (US). It is out-most important to review the morbidity and mortality of COPD in the US to make better healthcare decisions.

Objectives: To evaluate the prevalence, mortality, disease progression and associated co-morbidities of COPD in the US.

Methods: A comprehensive literature search was conducted in PubMed and Cochrane Library by combination of MeSH terms & keywords from May 2017 to May 2018. Google & Google Scholar was also searched for additional publications. The quality of included studies was assessed by Newcastle-Ottawa-Scale.

Results: The age-adjusted diagnosed COPD prevalence rate among adults aged ≥18-years was 5.9% (95% CI 5.8–6.0) in 2015. It was highly prevalent in West-Virginia (12.0%) & lower in Utah (3.8%). Age-standardised COPD mortality rate was 45.1 & 40.3 per 100,000 populations in 2014 and 2015, respectively and it was increased between 1980 and 2014 (34.5-to-45.1 deaths per 100,000 populations). Older age (β=0.03058), lower BMI (β=-0.0569), airway disease axis (β=0.64179), and CT intensity variability/noise (β=0.30924) were significantly (p<0.0001) associated with higher mortality. Almost half (49%; N=1105) of the COPD patients had at least one acute exacerbation. 7% & 2% of patients had at least one & ≥2 acute exacerbation each year, respectively. Mean number of overall & severe exacerbations were 1.5 & 0.48, respectively. COPD patients with previous exacerbations (5.22), ≥2-exacerbations in the year preceding enrolment (3.03), lower baseline FEV1 (0.93), younger-age (0.69) and higher CAT-score (1.11) significantly (p<0.001) higher odds to have at least one-exacerbation. Very commonly reported co-morbidities in COPD patients were hypertension (46-63.2%), diabetes (28.3-31%), affective disorders (27%), congestive heart failure (26.9%), and fluid and electrolyte disorder (23.4%).

Conclusions: COPD is highly prevalent and associated with significant morbidity, and mortality in the US.

4456 | Estimating chronic obstructive pulmonary disease prevalence in Portugal using pharmacy sales data

António T. Rodrigues[1], Rúben Pereira[1], Mariana Romão[1], Peter Heudtlass[1], José Guerreiro[1] and José Alves[2]
[1]Associação Nacional das Farmácias (ANF), Lisbon, Portugal; [2]Fundação Portuguesa do Pulmão (FPP), Lisbon, Portugal

Background: The prevalence of a disease is among the most fundamental measures in epidemiology. Though estimation methods based on primary sources are the gold standard for assessing prevalence, these are resource intensive and consequently limit reproducibility and periodicity. Recent estimations of prevalence of Chronic Obstructive Pulmonary Disease (COPD) in Portugal date from 2014 (assessed by self-reporting: 5,8% of the population) and 2016 (assessed using BOLD methodology: 14,2% of the individuals over 40 years living in

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Lisbon). However, discussion on whether the estimates are overvalued still resides among healthcare practitioners as only 132.000 COPD diagnosed patients were referenced to the national health service.

Objectives: The present study aims to estimate the prevalence of patients on medication for COPD in Portugal based on sampled data from medical prescriptions and on dispenses in community pharmacies nationally.

Methods: The average medication used for a 12-months period, at the patient level, was extrapolated from prescribed therapeutic regimens comprising at least one specific medication for COPD. This estimate considered average daily dosage, treatment duration, and class-specific Medication Possession Ratio (MPR) as reported in the literature. The prevalence in the population was estimated by distributing the total of dispenses of any COPD medication, nationally and per region, considering the calculated average medication used per patient in each therapeutic regimen.

Results: The estimated prevalence of treated COPD in Portugal in the 12-month period from Sep'18 to Aug'19 was 2,05% (≈210.700 patients). Attending to gender specific prescriptions and population distribution, we estimate this prevalence to be 2,80% in men (≈136.000 pts) whereas in women the prevalence is approximately half (1,38%, ≈74.700 pts). Estimates at the regional level range from 0,79% in Beja (≈1.125 pts) and 4,80% in Santarém (≈20.700 pts).

Conclusions: The number of treated COPD patients presented supports the underdiagnosis of COPD in Portugal, when compared to the prevalence estimates based on the gold standard for diagnosis. This suggests only individuals under treatment are likely to be known to the national health service. This study reinforces the role of the data available from community pharmacies on the assessment of the real burden of diseases. The presented estimation method retains national and regional representativity of the data used, enables stratified estimates and continuous monitoring of the number of individuals treated for COPD and may be applicable to other diseases.

4647 | Adverse events after acute kidney injury admission: A cohort study in the UK clinical practice research datalink

Patrick Bidulka, Kathryn Mansfield, Viyaasan Mahalingasivam, Dorothea Nitsch and Laurie Tomlinson

London School of Hygiene & Tropical Medicine, London, United Kingdom

Background: There is ongoing intense debate on how to best treat people discharged following acute kidney injury (AKI), particularly in those taking angiotensin-converting enzyme inhibitor (ACEI) or angiotensin receptor blocking (ARB) drugs. In order to understand key differences between the ACEI/ARB users and all individuals admitted for AKI (that may limit generalisability of any findings within the ACEI/ARB subgroup) it is important to describe the overall population admitted for AKI compared to a sub-group of ACEI/ARB users.

Objectives: To describe an overall UK population admitted to hospital with AKI and the sub-population who are prescribed ACEI/ARB in terms of baseline characteristics, death or dialysis during and after AKI hospitalisation, prescribing patterns before and after AKI admission, and subsequent readmissions.

Methods: We conducted a cohort study using linked UK primary and secondary care data from the Clinical Practice Research Datalink (CPRD) and Hospital Episode Statistics (HES). Participants were admitted to hospital for AKI (2010-2016), without a history of previous AKI, end-stage renal disease, or dialysis. Main outcome measures were ACEI/ARB prescription after discharge following AKI, mortality, and re-admissions (overall and cause-specific [heart failure, AKI, stroke]). We described the incidence of outcomes in the overall cohort admitted for AKI, as well as ACEI/ARB users using absolute rates stratified by follow-up period, Kaplan-Meier curves, and mean and median length of admissions.

Results: In the overall cohort (n=18,034) admitted for AKI, mean age was 77 (SD 14) with 48% female. 48% had chronic kidney disease (CKD) stage 3 or worse, 25% heart failure, and 52% were ACEI/ARB users. During the AKI hospitalisation, 679 (4%) received dialysis and 2524 (14%) died. Of those discharged (n=15510), 76% were readmitted within 2 years. The most common readmission primary diagnoses were AKI (7%), urinary tract infections (6%), pneumonia (5%), heart failure (3%), and chronic obstructive pulmonary disease (COPD) (1.6%). ACEI/ARB users had the same pattern of readmissions following initial AKI admission.

Conclusions: Infections and further AKI are among the most common causes of re-admission following AKI hospitalisation. Overall readmission and mortality rates are high in both the overall and ACEI/ARB users cohorts. Further research should investigate why infections are so common in people discharged after AKI hospitalisation.

4667 | Prevalence and baseline characteristics of dialysis and non-dialysis dependent CKD patients with and without anemia: A US cohort from DISCOVER-CKD

Eric Wittbrodt[1], Juan Jesus Carrero[2], Glen James[3], Steven Fishbane[4], Supriya Kumar[1], Roberto Pecoits-Filho[5,6], Juan Jose Garcia Sanchez[3], Carol Pollock[7], James Sloand[1], Katarina Hedman[8] and David Wheeler[9]

[1]AstraZeneca, Gaithersburg, MD; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Cambridge, United Kingdom; [4]Northwell, New York, NY; [5]Pontifical Catholic University of Parana, Curitiba, Brazil; [6]Arbor Research, Ann Arbor, MI; [7]University of Sydney, Sydney, Australia; [8]AstraZeneca, Gothenburg, Sweden; [9]University College London, London, United Kingdom

Background: Anemia is a frequent complication of chronic kidney disease (CKD), with prevalence increasing as kidney function declines and is associated with adverse clinical outcomes and reduced quality of life.

Objectives: To describe prevalence and baseline characteristics of CKD patients with and without anemia in a US cohort from DISCOVER CKD.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: DISCOVER-CKD is an international observational study in patients with CKD. The DISCOVER-CKD retrospective US cohort of patients was extracted using real world data from the integrated Limited Claims and Electronic Health Record data (IBM Health, Armonk, NY). The study cohort included patients aged greater than 18 years with diagnostic CKD code (stage3A through end stage renal disease or renal replacement therapy (RRT)) or 2 estimate glomerular filtration rate (eGFR) measures less than 75 mL/min/1.73m^2 at least 90 days apart between 1st January 2008 and September 2018. The index date was the first hemoglobin (Hb) measure on or up to 1-year after any of the following: the first diagnostic code for CKD or RRT, or initial eGFR; all patients require a second confirmatory eGFR which qualifies the patient to be part of the DISCOVER CKD cohort. Exclusion criteria was: less than 1-year registration/medical history prior to index, active bleeding in the 30 days preceding and inclusive of index and no Hb measure within a year after CKD diagnosis. Descriptive analyses were used to summarize prevalence and patient characteristics according to World Health Organization anemia categories.

Results: Of the 55495 CKD patients meeting our I/E criteria, 43700 (78.7%) where not anemic at baseline (Hb (g/dL) greater than 12/13 (female/male)). In anemic patients: 9743 (17.6%), 1665 (3.0%) and 387 (0.7%) had a baseline Hb of 10-12/13 (female/male), 8-10 and less than 8, respectively. Compared to non-anemic patients: anemic patients at baseline were older (68-70 years vs 63 years), more likely female (50-60% vs 56%), more likely to have comorbidities including hypertension (55-62% vs 47%), heart failure (15-28% vs 5%), type 2 diabetes (26-32% vs 16%), had more advanced CKD (mean eGFR 48-56 vs 64) and were more likely to be prescribed medications. Patients with more severe anemia (Hb less than 8) were more likely to receive iron (10%) or blood transfusions (15%) but not ESAs (0.3%).

Conclusions: In routine clinical care, the presence and severity of anemia increases as CKD advances. Patients with anemia have a higher comorbidity burden, lack of transfusion history and treatment for anemia at baseline was rare and almost absent in patients with Hb less than 10.

4686 | Using over-the-counter medication sales and the moving epidemic method for flu surveillance in Portugal (2016-2020)

Peter Heudtlass[1], Nuno Rodrigues[2], António T. Rodrigues[1], Rúben Pereira[1] and Zilda Mendes[1]

[1]Associação Nacional das Farmácias, Lisboa, Portugal; [2]Agrupamento de Centros de Saúde Oeste Sul, Torres Vedras, Portugal

Background: Most patients with influenza-like illness (ILI) do not see seek medical attention immediately, if at all. This potentially leads to a lag in detecting the start of flu epidemics and in predicting their peak, when using primary care case load data for surveillance.

Objectives: To model seasonal influenza with the Moving Epidemic Method (MEM) using over-the-counter (OTC) sales instead of health care case load data and to estimate the sensitivity and specificity of this model. To test whether our data can detect beginning and peak of the 2019/2020 influenza epidemic earlier than models based on primary care data.

Methods: Using a time-warping algorithm and time series correlations, we define a basket of OTC products that explains best the variation in ILI cases reported by primary care units in the health zone Oeste Sul, north of Lisbon, Portugal, during five previous flu seasons (2014-2019). We fit a MEM model with the total Portuguese sales of these products in the same period and estimate the model's sensitivity and specificity. Using this model and OTC sales of the influenza season 2019/2020 in Portugal, we estimate beginning and peak of the 2019/2020 epidemic and compare this to primary care case load data.

Results: We estimate that the MEM model calibrated with OTC data from 2014-2019 has a sensitivity of 80.4% and a specificity of 83%. Using the fitted model for surveillance, it allows us to detect the beginning and the peak of the 2019/2020 before they are observable in the primary care case.

Conclusions: Data from OTC sales in community pharmacies can complement and strengthen flu surveillance in Portugal.

4702 | Mortality in preterm infants with bronchopulmonary dysplasia associated pulmonary hypertension: A systematic literature review

Laura Downham, Sofija Cerovic, Catherine Lesage and Sandrine Leroy

Actelion Pharmaceuticals Ltd, Allschwil, Switzerland

Background: Pulmonary hypertension (PH) is a common complication of bronchopulmonary dysplasia (BPD) in preterm infants and worsens outcomes in these patients with other competing mortality risk related to multiple comorbidities (cerebral palsy, infections, enterocolitis). Mortality estimates are unclear in the literature, and its relationship to BPD-PH specifically.

Objectives: To provide an up-to-date overview of mortality in infants with BPD-PH through a systematic literature review.

Methods: A systematic literature search of Medline and Embase was conducted and included observational studies in paediatric BPD-PH patients and mortality data. Mortality proportion (MP; rate of death over the study sample size) was explored in regards with all available factors to better explore its heterogeneity across studies.

Results: 25 studies (n=2179 BPD-PH patients) were included, 84% were retrospective, and 76% were conducted in North America. PH diagnosis was based on a combination of echocardiographic criteria in 96% of the studies. When reported, all studies included preterm infants with gestational age (GA) <28 weeks. The MP ranged from 4.0% to 52.8% (median: 13.0%) while the 2-year survival estimate (n=5 studies) ranged from 35.0% to 80.0% with a steep decrease in survival between 6 months and 1 year, then stabilisation. In studies with follow-up ≥1 year, median MP was of 20.8%, ranging from 11.1% to 28.0%; studies with shorter follow-up offered more heterogeneity. Independently of the time of follow-up, the median MP was higher in the studies where PAH was diagnosed later than 40 weeks GA, likely due to an immortal bias leading to inclusion of only

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

surviving infants with a high all-causes mortality in their first weeks of life. As expected, there was an inverse relation between MP and birthweight that reflected the degree of immaturity of pulmonary and vascular tracts leading to severe BPD-PAH disease. Causes of death were reported in 52.0% of the studies, and were not clearly related to PAH, highlighting the multiplicity of factors that lead to the high mortality rate observed. The methodological quality of the included studies was acceptable (STROBE median score of 14.8- Q1, Q3: 13.7, 16.2).

Conclusions: This systematic literature review demonstrated that mortality estimates were highly heterogeneous, due to immortal bias, follow-up duration, GA limit to define BPD-PH, and birth weight. Registries with standardised definitions, longer follow-up would be of interest to better estimate mortality, and its direct relationship to BPD-PH in preterm infants.

4707 | Identifying chronic kidney disease in a laboratory database: Setting does matter

Uffe Heide-Jørgensen[1], Christian F. Christiansen[1], Henrik Birn[1,2], Reimar W. Thomsen[1] and Søren V. Vestergaard[1]

[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aarhus University, Aarhus, Denmark

Background: Chronic kidney disease (CKD) is usually diagnosed based on the glomerular filtration rate (GFR). Estimated GFR (eGFR) can be assessed from serum creatinine, making laboratory databases an excellent data source for patient identification in pharmacoepidemiological studies of CKD. However, during hospitalization and emergency room visits eGFR may not correctly reflect the patient's normal GFR due to acute illness.

Objectives: To investigate differences between CKD patient cohorts identified using serum creatinine tests from outpatient settings only, compared with using all tests regardless of setting.

Methods: We conducted this cohort study in 2009-2016, using a population based laboratory database containing results from all creatinine blood tests from primary, secondary and tertiary care in Northern Denmark. Tests taken on days where a person was hospitalized or visited an emergency room (ER) were flagged. We identified patients with CKD as anyone with at least two tests showing eGFR < 60 mL/min/1.73m^2 at least 90 days apart, with the second being the index date. We did this using only unflagged blood tests (outpatient), and using all tests (total), resulting in two cohorts. We followed patients until death or emigration using the Civil Registration System. For both cohorts, we described baseline characteristics and estimated mortality using the Kaplan Meier approach. In sensitivity analyses we required just one test tests showing eGFR < 60 mL/min/1.73m^2 to define CKD.

Results: The outpatient and total cohorts included 84,688 and 95,213 patients, and the median age was 74 years in both. The median (interquartile range) time from first to second CKD defining blood test was 13 (6-35) months in the outpatient and 15 (6-41) months in the total cohort. The 1-year mortality was 8.2% (95% confidence interval [CI] 8.0-8.3) in the outpatient cohort and 12% (95% CI 11-12) in the total cohort. The difference in mortality between the outpatent and total cohorts attenuated over time, after 8 years the corresponding mortalities were 45% (95% CI 44-46) and 46% (95% CI 45-47). In the sensitivity analyses, we identified 103,435 and 123,841 patients with median ages of 71 and 70 years in the outpatient and total cohorts. The cohorts were similar with respect to baseline characteristics but the difference in mortality was more pronounced than in the main analyses.

Conclusions: The distribution of baseline characteristics in CKD patient cohorts was not affected much by the in- or exclusion of creatinine blood tests from inpatient or ER settings. However, inclusion of all tests increased both the number and mortality of patients included in the cohorts.

4774 | Development of novel algorithms to identify cases of focal segmental glomerulosclerosis in a large electronic medical record database

Irene Cosmatos[1], Cynthina de Luise[2], J. Brian Copley[2], Daniel I. Levy[2], Nihad Tamimi[2], Stephen Berasi[3], Donal Gorman[4], Michael Bulgrien[1] and Gretchen Dieck[1]

[1]UBC, Blue Bell, PA; [2]Pfizer, New York City, NY; [3]Pfizer, Cambridge, MA; [4]Pfizer, Cambridge, United Kingdom

Background: Health authorities are increasingly accepting real world data (RWD) to support regulatory decision-making. Access to large, clinically rich, geographically representative electronic medical record (EMR) databases and other RWD enable the conduct of real world studies to inform natural history of disease and assess disease prevalence.

Objectives: To develop laboratory-based computer algorithms to identify cases of focal segmental glomerulosclerosis (FSGS), a rare kidney disease with clinically diverse etiology, in Humedica, a national level EMR database reflecting the age, gender, geographic, and racial diversity of the United States population.

Methods: The prevalent 2017-2018 glomerulonephritis (GN) disease population in Humedica, of which FSGS is a subset, was assessed to gain insight into relevant diagnoses (e.g., nephrotic syndrome), procedures (e.g., kidney biopsy), laboratory tests, and demographics needed to identify potential cases of primary and secondary FSGS. Next, a team of expert nephrologists conducted an in-depth clinical review of detailed EMR-generated profiles of patients who broadly qualified as potential cases of FSGS based on a combination of relevant lab results, diagnoses, and procedures. Key factors that influenced the determination of FSGS case status included age, evidence of nephrotic range proteinuria, FSGS ICD-10 codes, evidence of a kidney biopsy, and exclusions due to comorbidities related to nephrotic range proteinuria (e.g., diabetes).

Results: Among >30,000 patients with diagnoses of GN, the distribution of GN subtype by race demonstrated an increased frequency of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

nephrotic syndrome diagnoses in general, and FSGS in particular, among African-Americans vs. Caucasians and Asians. Expert nephrologists established a set of computer algorithms to identify primary and secondary FSGS cases in Humedica, with the likelihood of case status ranging from 'definite' to 'uncertain.' Only patients with a documented kidney biopsy could be classified as 'definite', based on laboratory results and the frequency and timing of FSGS diagnoses. Algorithms were specific to age group (<10 yrs vs. ≥10 yrs), as the disease presents differently in children.

Conclusions: These original algorithms represent the first opportunity to create FSGS diagnostic groups of increasing levels of certainty depending on available evidence in a patient's EMR data. Upper and lower ranges of primary and secondary FSGS prevalence can then be estimated in a representative US population according to important disease risk factors of age, gender, and race.

4799 | The association between the use of long-term antibiotics used to treat acne vulgaris and subsequent infection sequelae and antimicrobial resistance: A systematic review

Ketaki Bhate[1], Liang-Yu Lin[1], John Barbieri[2], Sarah-Jo Sinnott[1], Rohini Mathur[1] and Sinead Langan[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom; [2]University of Pennsylvania, Philadelphia, PA

Background: Antimicrobial resistance (AMR) is a global health priority. Acne vulgaris is a highly prevalent skin condition predominantly of adolescence and antibiotics are widely used in its treatment. Average antibiotic use for acne ranges from a few months to years of daily exposure.

Objectives: To systemically search for and synthesise evidence on the role of long-term oral antibiotic use for acne in increased risk of infections unrelated to acne or other outcomes suggestive of AMR.

Methods: The following databases were searched: Embase, MEDLINE, Cochrane and Web of Science, using MeSH, EMTREE or other relevant terms. Search strategies were developed in collaboration with a librarian and run in July 2019. All searches date from database inception. Inclusion criteria: Randomised controlled trials, cohort or case control studies investigating oral antibiotics of any class for a minimum of 28 days in individuals over 8 years old, compared to people with acne not treated with oral antibiotics, or the general population. Exclusion criteria: Ecological studies and studies that did not assess temporality. Studies investigating topical antibiotics or Cutibacterium acnes. The primary outcome was antibiotic treatment failure or infection caused by a resistant organism. The secondary outcome was the detection of resistant organisms without an infection, rate of infection, or changes to flora. Three reviewers independently screened the search results based on title and abstract. Full-text papers were assessed independently using a standardised pilot-tested data extraction form. ROBINS-I was used to assess the risk of bias and GRADE was used to make an overall assessment of quality of evidence.

Results: 6996 records were identified for title and abstract screening. 73 full-text articles were shortlisted for full review, of which five articles were included. Two investigated infection rates and three identified resistance or changes to microbial flora; all were cohort studies from high income western countries. Three studies had 35 or fewer participants (range 20-118,496). Given heterogeneity, meta-analysis was not possible. Three studies had a 'serious' risk of bias and two a 'moderate' risk of bias. Findings suggest there may be an association with an increased rate of upper respiratory tract infections and pharyngitis.

Conclusions: There is an outstanding gap in our understanding of the relationship between oral antibiotics used to treat acne and infectious sequelae and AMR. This needs to be urgently addressed with rigorously conducted studies.

4894 | Digitization of physical behaviors

Marie Mc Carthy, Paul Nolan, Antonio Lampasi, Jialiang Chen and Michal Skackov

ICON PLC, Dublin, Ireland

Background: This study looks at the feasibility of extracting clinically relevant digital data from wearables. This data has significant potential as real world data particularly as they evolve to more robust and reliable sources of data with many manufacturers pursuing regulatory pathways.

Objectives: To architect a cloud based platform to facilitate the storage of large datasets from wearables and advanced analysis of the ingested data. T

Methods: Employees who own a Fitbit were recruited by email, 10 consented and were sent a link to the authorization application (app). An analysis of clinical trials.gov to identify endpoints from studies where wearable data had supported outcomes. The platform was built with a multi-cloud strategy. Microsoft's Azure cloud platform hosted the app used to authorize participants data collection. Amazon Web Services Cloud (AWS) was used to implement the backend data collection, processing and analytics. Serverless technologies were deployed in AWS resulting in a highly scalable architecture. Data generated was pushed into Microsoft's Power BI cloud to enable analytics and visualizations to reflect the endpoints identified.

Results: Fitbit were used in 276 of the 361 studies identified. Outcome measures mapped to broad categories; Physical Activity, Sleep, Heart Rate and Wear Compliance each category consisting of a variety of individual endpoints. Over an 87 day period 54048 steps, 9595 sleep and 541421 heart-rate data points were captured. Analytics were developed to map to the identified endpoints. The average steps/day was 4,396, this figure was consistent for weekday and weekends. There was a 30% reduction in steps over the period December 25th and 26th. There was a corresponding decrease in Moderate and Vigorous physical activity with 0 hr recorded on the 25th of December. There was a similar reduction in the percentage time spent in the cardio range of heart rate patterns going from

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

0.65% to 0.34% on that day. The sleep pattern showed a reduction in REM sleep as a percentage of the overall sleep pattern.

Conclusions: The growing availability of wearables among the general population, is an untapped digital data resource. A BYOD model is feasible to track physiological changes using advanced analytics to convert large data streams into clinically meaningful endpoints. Currently the BYOD model pertains only to devices from a single vendor as aggregating data from different wearables is challenging as manufactures use different accelerometers, sampling rates and algorithms to generate physical activity, sleep data. In addition it is likely an RWE study would require a mix model with both provisioned and a BYOD approach.

4987 | People living with HIV with higher CD4+ lymphocyte counts rated their own health as good

Cristiane A. Menezes de Pádua[1], Letícia P. Braga[2], Isabel N. Santos[2], Letícia F. Silva[2], Bianca R. Guerra[2], Joyce C.M. Faria[1] and Cassia C.P. Mendicino[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [2]Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

Background: Antiretroviral therapy has markedly contributed to the increase of life expectancy and quality of life of people living with HIV. Self-rated health is a sensitive measure of easy application, which is related to morbidity and mortality.

Objectives: To assess the factors associated with good self-rated health among people living with HIV on long-term antiretroviral therapy.

Methods: Cross-sectional study with 85 treatment-experienced individuals from Belo Horizonte, Brazil. Self-rated health was obtained through the interview question: "How much are you satisfied with your own health?" based on a 5-point scale (1=very unsatisfied, 2=unsatisfied, 3=satisfied nor unsatisfied, 4=satisfied and 5=very satisfied). Patients were grouped into two categories, according to their responses: good self-rated health (4 or 5) or bad self-rated health (1, 2 or 3). Socio-demographic, behavioural/lifestyle and clinical/laboratory variables were obtained from interviews and review of medical charts. Binary logistic regression was used to assess the association between good self-rated health and exposure variables estimated through odds ratios (OR) with 95% confidence intervals (CI).

Results: Fifty-seven (67.1%) participants rated their health as good. Most patients were men (54.1%), aged 50 years or older (57.7%), had non-white skin colour (84.3%) and reported current consumption of alcohol (70.6%). Approximately 30% of patients were on treatment with lamivudine/tenofovir and efavirenz, 32.9% reported current use of tobacco and 46.5% had regular physical activity in the previous 12 months. The majority of the participants had undetectable (< 50 copies/mL) viral load (81.2%), T-CD4+ count >500 cells/μl (76.5%) and had at least one comorbidity during their HIV/AIDS treatment (62.3%). LT-CD4+ count >500 cells/μl (OR=3.27; CI95%=1.03-10.34) and absence of comorbidity were independently associated with a good self-rated health (OR=6.63, CI95%=1.93-22.71).

Conclusions: The proportion of good self-rated health was similar to that found in other national studies. Characteristics related to the HIV infection appeared to have impact on the self-rated health of the participants rather than behavioural/lifestyle or socio-demographic variables. LT-CD4+ count >500 cells/mm^3 is related to reduced risk of disease progression and death, thus it might contribute to the perception of being healthy. Therefore, the monitoring on immunological response is important to ensure higher life expectancy and better quality of life of people living with HIV.

5003 | Analysis of a large cohort of patients with erythema multiforme majus: Epidemiology, clinical pattern and risk factors

Maja Mockenhaupt, Susanne Martin and Maren Paulmann

Medical Center - University of Freiburg, Freiburg, Germany

Background: Erythema multiforme majus (EMM) is a severe reaction affecting skin and mucous membranes. For decades EMM has erroneously been considered to be the same as Stevens-Johnson syndrome (SJS), leading to false conclusions in terms of etiology. However, a consensus definition (Bastuji-Garin et al, 1993), which was further specified (Schröder et al, 1999), allows to separate EMM from SJS, and differentiate between a typical and atypical form of EMM.

Objectives: Demographic data, clinical pattern and risk factors of EMM are investigated in a large cohort of validated cases, and compared to those seen in SJS.

Methods: Since 1990 the German Registry has ascertained hospitalized cases of severe skin reactions including EMM. From Jan 2003 these cases entered the multinational RegiSCAR-study. For this analysis all potential cases of EMM collected from this time onwards until Aug 2017 were investigated. They were clinically reviewed by an expert committee blinded for potential causes based on the definitions referenced above.

Results: Of 312 EMM-cases 219 were validated as "definite", 72 as "probable", 21 as "possible. Of these, 192 cases were typical EMM, 119 atypical EMM; 1 case could not be determined. Men were much more often affected than women (204 vs. 108). Children and adolescents <18 yrs accounted for 65% of cases, 2/3 of them were male. Cases occurred throughout the year but clustered Nov - Feb. No death was observed in this EMM-cohort. In all cases at least 1 mucous membrane was affected by hemorrhagic erosions. On average, 4 mucosal sites were erosive, most frequently oral cavity (99%), lips (98%) and genital mucosa (86%). In 33% of patients, severe conjunctivitis was diagnosed. The type of lesions could be analyzed in 309 cases: 85% had typical targets, 39% atypical raised targets. In cases of typical EMM the average amount of skin involvement was 4%, with <2% of detachment. In contrast, the amount of skin involvement in atypical EMM was much higher with up to 40% and detachment with up to 10%. In 81% of definite and probably cases (n=291) the reaction was preceded by an infection. Most frequently this was a

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

respiratory infection, and in 55% of patients, mycoplasma pneumoniae was identified. In 18% of the cases a herpes simplex-eruption took place before EMM. Medications with a high risk to induce SJS and toxic epidermal necrolysis (TEN) could only be identified in 1 patient, who suffered from an infection that was treated with sulfamethoxazole.

Conclusions: These data clearly demonstrate that EMM must be differentiated from SJS/TEN and should be viewed as an infection-induced condition, and not as a drug eruption.

5038 | Prevalence of eosinophilia in the United States

Hoa V. Le[1], Chi H.H. Le[2], Phuong H.U. Le[3] and Chi T.L. Truong[4]
[1]*Bristol-Myers Squibb, Berkeley Heights, NJ;* [2]*School of Medicine, Vanderbilt University, Nashville, TN;* [3]*University of Toronto, Mississauga, ON, Canada;* [4]*MedCodeWorld, Chapel Hill, NC*

Background: An accumulation of eosinophils in the blood is observed in certain disease states such as atopy, allergy or parasitic infections. Due to tissue infiltration and subsequent inflammation and fibrosis, a marked rise in eosinophils has been associated with critical organ-damage. However, there is a paucity of data examining eosinophilia in the general population.

Objectives: To determine the prevalence of eosinophilia and hypereosinophilia in a nationally representative sample of the U.S. population.

Methods: Eosinophilia and hypereosinophilia cases, defined as individuals with eosinophil count over 500/uL and 1500/uL respectively, were identified in the National Health and Nutrition Examination Survey (NHANES) 2015-2016. Prevalence and 95% CIs were analyzed in the overall sample and by age groups, sex, and race/ethnicity. Multivariate logistic regression was performed to compare prevalence among different subgroups. Statistical analyses accounted for complex survey design with examination sample weights and adjusted for nonresponse. Sensitivity analyses included unadjusted, gender- and age-adjusted modeling. Statistical significance was determined by 2-sided p value of 0.05.

Results: Among 8,116 U.S. individuals from 2015-2016, the overall prevalence of eosinophilia and was hypereosinophilia were 8.2% (95% CI: 7.2-9.2%) and 0.14% (95% CI: 0.07-0.21%), respectively. Rates of eosinophilia were significantly higher in men than in women 10.3% (95% CI: 8.7-12%) vs. 6.2% (95% CI: 5.3-7%), $p < 0.0001$. Among different age groups, eosinophilia was observed at significantly higher rate in children aged ≤ 11 years (17.3%, 95% CI: 15.4-19.3). Sensitivity analyses adjusted for age- and/or gender- showed similar trends. Moreover, non-Hispanic blacks had lower rates of eosinophilia in comparison non-Hispanic whites (7.2% vs. 8.3%, p=0.048). Among the study population, the mean, median and IQR of eosinophil count were 214/uL, 120/uL and 51-219/uL, respectively.

Conclusions: These findings provided an updated depiction of the prevalence of eosinophilia and hypereosinophilia in the general US population. In addition to known comorbidities, our study identifies potential high-risk groups for eosinophilia including men and children ≤ 11 years old.

5063 | Use of administrative health databases to estimate incidence and prevalence of rheumatic arthritis in the general population

Francesco Barone-Adesi, Andrealuna Ucciero, Gianmarco Cotrupi and Antonio Isabella
University of Eastern Piedmont, Novara, Italy

Background: Unrecognized and untreated Rheumatic Arthritis (RA) leads to serious clinical complications with adverse outcomes for patients and increasing costs for the health care system. Hence, adequate knowledge of the epidemiological features of such a condition is desirable to plan effective interventions. However, currently available information is mainly derived from data collected in specialized referral centers, whose catchment areas may not cover the whole population.

Objectives: The aim of our study was to use administrative data sources to estimate incidence and prevalence of RA in the general population of a large Italian region.

Methods: A retrospective cohort study was conducted using Administrative Health Databases of Piedmont, an Italian Region with a population of 4.3 million inhabitants, during the period 2012-2018. RA cases were defined as the subjects who had at least one of the following claims: i) Hospital discharge records with RA diagnosis code; ii) Exemption from co-payment for RA; iii) Prescription of one of the following medications: tocilizumab, abatacept, leflunomide, sodium aurothiomalate, sodium aurotiosulfate, auranofin. Prevalence was calculated by dividing the number of prevalent cases of RA (i.e., those with RA-related claims at any time during the period 2012-2018) by the total number of residents in Piedmont. Incidence was calculated by dividing the number of new RA cases (i.e., no evidence of RA during the 3 years prior to the index claim) by the size of the population total time at risk during the period 2015-2018. Clopper-Pearson and Byar methods were used to estimate the 95% confidence intervals (CI) for prevalence and incidence, respectively.

Results: The overall prevalence was 5.5 per 1000 inhabitants [95% CI 54-56], and the overall incidence 28 per 100,000-person years [95% CI 26-29]. Prevalence and incidence increased with age and were about 2-fold higher among women.

Conclusions: Administrative data source can represent a simple and inexpensive method to monitor patterns of RA in large populations. This study is part of the FOHN project, funded by the Italian Ministry of Education, University and Research.

Drug Effectiveness

94 | Drug survival of secukinumab, ustekinumab, and adalimumab in patients with psoriasis

Zenas Z.N. Yiu and BADBIR Study Group
University of Manchester, UK, Manchester, United Kingdom

Background: Biologic drug survival in the real world is an important proxy measure for effectiveness. Predictors of drug survival may help patients with psoriasis choose the right biologic first time.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: 1. To assess the relative drug survival of adalimumab, secukinumab and ustekinumab in patients with psoriasis; 2. To look for predictors for biologic drug survival in the same cohort.

Methods: The prospective cohort study was performed using data from the British Association of Dermatologists Biologics and Immunomodulators Register (BADBIR), a multicenter longitudinal pharmacovigilance registry of patients with moderate-to-severe psoriasis in the United Kingdom and Republic of Ireland between November 2007 and August 2019. The outcomes were survival functions after 1 and 2 years, separated by discontinuation reason; adjusted hazard ratios (adjHR) for adalimumab and secukinumab compared with ustekinumab; and adjHRs for the effect of the potential predictors of drug discontinuation due to ineffectiveness in a flexible parametric survival model.

Results: 9,652 participants were included in the study, with 5,542 starting on adalimumab (57.4%); 991 on secukinumab (10.3%); and 3118 on ustekinumab (32.3%) after registration. The overall drug survival of adalimumab, secukinumab and ustekinumab was 0.78 (95% CI 0.77-0.79), 0.88 (0.86-0.91) and 0.88 (0.87-0.89) in Year 1 respectively, dropping to 0.66 (0.64-0.67), 0.77 (0.73-0.80), and 0.77 (0.76-0.79) respectively in Year 2. Fourteen covariates were included. The adjHR for discontinuation of adalimumab and secukinumab compared with ustekinumab were 2.11 (1.76-2.54) and 0.67 (0.40-1.11) respectively. Psoriatic arthritis predicted for survival in the adalimumab and secukinumab cohorts (adjHR 0.67 (0.51-0.88); 0.70 (0.40-1.24) respectively) but for discontinuation in the ustekinumab cohort (adjHR 1.42 (1.12-1.81)), while having previous exposure to biologic therapies predicted for discontinuation in the ustekinumab and secukinumab cohorts (adjHR 1.54 (1.26-1.89); 1.49 (0.91-2.45) respectively) and for survival in the adalimumab cohort (adjHR 0.71 (0.55-0.92)).

Conclusions: Secukinumab and ustekinumab have similar sustained drug survival, while adalimumab has a lower drug survival in patients with psoriasis. We identified psoriatic arthritis and previous biologic experience as predictors of drug survival with differential effects between the biologic therapies.

99 | Treatment effectiveness, safety and health related quality of life in multiple myeloma: Evidence from the real world

Mir Mahmood Asrar[1], Dipika Bansal[1] and Deepesh P. Lad[2]
[1]*National Institute of Pharmaceutical Education and Research (NIPER) S.A.S. Nagar, Mohali, India;* [2]*Postgraduate Institute of Medical Education and Research, India, Chandigarh, India*

Background: Recent advances in the treatment of multiple myeloma (MM) have improved prognosis and increased disease-free and overall survival among patients. However, no study has been reported from India.

Objectives: This study aims to describe patients with MM their treatment and clinical outcomes, the comparative tolerability, effectiveness, health-related quality of life (HRQoL) and cost implications among different treatment groups.

Methods: A prospective single-center cohort study was conducted at hematology department, PGIMER Chandigarh, a tertiary care hospital in India. Baseline patient and MM-specific characteristics, diagnosis, comorbidities, and prior therapies, MM management, disease status, safety data, and cost details were recorded at baseline and follow-up based on a review of hospital/clinic records and patient interviews. HRQoL was measured using the Cancer Quality of Life Questionnaire (EORTC QLQ-C30) and the MM module (EORTC QLQ-MY20). Kaplan-Meier analysis was performed to determine progression-free and overall survival.

Results: A total of 75 patients were included; 60% were males and the mean age was 60.5±9.0 years. A statistically significant difference was observed in EQ-5D-5L domains like Usual activities and Health Status in patients with different ISS stages ($P<0.05$). A higher Very good partial response (VGPR) of 50% was reported in patients treated with Bortezomib, Lenalidomide, Dexamethasone(VRD) regimen relative to 27.3% receiving Bortezomib, Cycophosphamide, Dexamethasone (VCD). At 6-months follow-up, the significant reduction was reported in mobility [VCD: 2.53±1.02; VRD: 1.58±0.77, $p<0.05$], pain/discomfort [VCD: 2.32±1.11; VRD: 1.63±0.76, $p<0.05$] and health status [VCD: 64.37±22.86; VRD: 76.53±16.84, $p<0.05$]. The overall 6-month survival was comparatively lower in patients with higher albumin levels (3.5g/dL) $\chi 2 = 0.364$, $p = 0.547$. The average cost per cycle on the Cyclophosphamide, Thalidomide, Dexamethasone(CTD) regimen was lower 1339.9±229.6 Indian National Rupees compared to VRD and VCD.

Conclusions: HRQoL among MM patients were very low at diagnosis, but improved substantially after the initiation of novel MM regimens among treatment naïve patients. The rising out- of- the pocket cost of novel MM treatment raises the concern for affordability in developing countries.

105 | Effectiveness of proton pump inhibitors in idiopathic pulmonary fibrosis: A population-based cohort study

Tanja Tran[1,2], Deborah Assayag[1], Pierre Ernst[2] and Samy Suissa[1,2]
[1]*McGill University, Montreal, QC, Canada;* [2]*Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada*

Background: Gastroesophageal reflux disease is a common comorbidity in idiopathic pulmonary fibrosis (IPF) and is hypothesized to contribute to its progression. As treatment options for IPF are limited, anti-acid therapy, such as proton pump inhibitors (PPIs), has been conditionally recommended in international treatment guidelines for IPF. However, the evidence is inconsistent, where the observational studies that suggest a benefit are affected by immortal time bias.

Objectives: To assess the association between use of PPIs and all-cause mortality, respiratory-related mortality, and respiratory-related hospitalization in patients with IPF using a large population-based cohort.

Methods: We used the UK Clinical Practice Research Datalink to identify a cohort of patients diagnosed with IPF between 2003 and 2016. The prevalent new-user cohort design was used to match

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients initiating PPIs with non-users using time-based exposure sets and time-conditional propensity scores. Exposure sets were based on the first PPI prescription after IPF diagnosis (±1 month), with non-users having a record of a physician visit within the corresponding exposure set. Matched non-users could receive a PPI later during follow-up, so that their follow-up was censored and the patient could be included as a PPI user from that point onward. All study patients were followed until death or end of observation. Cox models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) of death and of a respiratory-related hospitalization, correcting for informative censoring by inverse probability of censoring weighting.

Results: There were 1852 PPI users matched to 1852 non-users identified among the cohort of patients with IPF, with median survival of 2.8 years. The HR of all-cause mortality with PPI use was 1.07 (95% CI 0.94-1.21), relative to non-use. For respiratory-related mortality the HR was 1.10 (95% CI 0.61-1.97) and 1.01 (95% CI 0.87-1.18) for respiratory-related hospitalizations.

Conclusions: In this large study conducted in patients with IPF within a real world setting of clinical practice, PPI use was not associated with lower mortality or hospitalization incidence. PPIs may not be as beneficial in treating IPF as suggested by some observational studies affected by major bias. The conditional recommendations for the use of these medication in treatment guidelines need revision.

2320 | The potential beneficial effects of low-dose aspirin for the primary prevention of gastrointestinal cancers: A population-based cohort study in Hong Kong

Jessica J.P. Shami[1], Jiaxi Zhao[1], Swathi Pathadka[1], Pareen Vora[2], Montse Soriano Gabarró[2], Ian Wong[1] and Esther Chan[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong; [2]Bayer AG, Berlin, Germany

Background: The effects of low-dose aspirin use in gastrointestinal cancers remain unclear in the general Chinese population.

Objectives: To evaluate associations between the use and duration of low-dose aspirin and the risk of colorectal cancer (CRC), gastric cancer (GC), and esophageal cancer (EC) in Hong Kong.

Methods: We conducted a retrospective population-based cohort study, using the Clinical Data Analysis and Reporting System (CDARS), an electronic clinical database managed by the Hong Kong Hospital Authority. Patients prescribed either low-dose (75-300mg/daily) aspirin or paracetamol (reference exposure) between January 2004 and December 2008 were matched (without replacement) by propensity score at a 1:1 ratio with follow-up until December 31, 2017. Potential confounders included age, sex, a list of comorbidities and concurrent medications. The primary outcome was an incident diagnosis of gastrointestinal cancer (either CRC, GC, or EC) identified using ICD-9 codes (International classification of diseases, 9th revision). The follow-up period started from the first prescription of either low-dose aspirin or paracetamol (i.e. index date) until the occurrence of outcome, any cancer diagnosis, death, or end of study period (December 31, 2017) whichever came first. We used competing risk Cox regression with death as the competing risk to generate hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: We included 166,466 low-dose aspirin or paracetamol users. The mean (standard deviation) follow-up was 8.7 (4.2) years for low-dose aspirin users and 9.0 (4.3) years for paracetamol users. The incidence rates of CRC, GC, and EC were 20.4, 5.4, and 2.2 per 10,000 person-years respectively for low-dose aspirin users and 22.9, 6.8, and 2.9 respectively for paracetamol users. Low-dose aspirin (vs. paracetamol) use was associated with a reduced risk of CRC, GC, and EC (CRC: HR = 0.88 [0.82-0.94]; GC: 0.77 [0.68-0.88]; EC: 0.72 [0.59-0.89]). Low-dose aspirin use for ≥3 years was associated with a reduced risk of CRC, GC, and EC (CRC: HR = 0.74 [0.67-0.82]; GC: 0.43 [0.35-0.52]; EC: 0.43 [0.32-0.59]) compared to <3 years low-dose aspirin use.

Conclusions: The use of low-dose aspirin was associated with a significant reduced risk of CRC, GC and EC among the study cohort. The use of low-dose aspirin for more than 3 years was more protective of CRC, GC, and EC compared to less than 3 years low-dose aspirin use.

2353 | Impact of maternal depression during pregnancy and its treatment options on fetal health: A prospective cohort study of 84,000 pregnant women

De-Kun Li[1], Jeannette R. Ferber[1], Roxana Odouli[1], Charles Quesenberry[1], Lyndsay A. Avalos[1], Mason Turner[2] and Tracy Flanagan[3]

[1]Kaiser Foundation Research Institute, Kaiser Permanente, Oakland, CA; [2]Kaiser Permanente Hawaii, Wailuku, HI; [3]Kaiser Permanente, Oakland, CA

Background: Maternal depression during pregnancy is prevalent and its impact on fetal health remains uncertain. The risk-benefit profile of its treatment remains unclear due to a lack of control for the underlying depression in previous studies.

Objectives: To determine the risk of preterm delivery (PTD) associated with untreated depression and risk-benefit profiles of its treatment options, and whether those profiles are impacted by the presence of psychiatric comorbidity.

Methods: To disentangle the contribution of untreated depression from that of its treatments to the risk of PTD, we conducted a prospective cohort study among 84,912 pregnant Kaiser Permanente Northern California members. Clinically diagnosed depression, its treatments, PTD, and confounders were obtained from electronic medical records. A sub-cohort of more than 3,000 women were interviewed to collect additional information on confounders and compliance with use of prescribed antidepressants. The Cox proportional hazards regression was employed to account for PTD at various gestational ages.

Results: After using propensity score methodology to control for confounders and ensure comparability between cohorts, when compared to those without depression, pregnant women with *untreated*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

depression had 41% increased risk of PTD: adjusted hazard ratio (aHR)=1.41, 95% confidence interval (CI)=1.24-1.60. Compared to untreated depression, treating depression with antidepressants during pregnancy was associated with an additional 31% increased risk of PTD: aHR=1.31, 95% CI=1.06-1.61. There was a dose-response relationship with higher PTD risk associated with a longer duration of use. In contrast, mental health counseling was associated with a decreased risk of PTD: aHR=0.82 (0.71-0.96). This mitigating effect also showed a dose-response relationship with more visits being associated with a greater reduction in PTD risk. These associations were consistently observed regardless of the presence of psychiatric comorbidities. Sensitivity analyses, including adjustment for additional factors collected through interview of a sub-cohort, did not change the above observations.

Conclusions: Our results isolate the effect of depression from its treatment, and show that maternal depression during pregnancy, if not treated, increases the risk of PTD. Antidepressant treatment further increases the risk, and, in contrast, mental health counseling reduces the risk of PTD associated with depression. Thus, different treatment approaches during pregnancy could have different risk-benefit profiles.

2395 | Assessment of clinical outcome of twice daily dosing schedule of deferasirox in transfusion dependent paediatric beta thalassemia patients a randomized controlled study

Juny Sebastian, Tirin Babu, George Mathew Panachiyil and Mandyam Dhati Ravi

JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, India

Background: Deferasirox has proven good efficacy and acceptable safety for the management of thalassemia patients. However, some patients are unresponsive or intolerant to once daily administration of deferasirox even at a high dose.

Objectives: To evaluate the efficacy and tolerability of twice daily dosing of deferasirox among transfusion dependent paediatric beta thalassemia patients.

Methods: This prospective randomized single blinded parallel study was conducted at the Pediatric Hematology clinic of a tertiary care hospital over a period of one year. Study enrolled transfusion dependent paediatric beta thalassemia patients prescribed with deferasirox who visited the study site for their regular blood transfusions and follow up. All the eligible subjects were randomized by block randomization method to intervention and control group. Once daily dosing of deferasirox was changed to twice daily dosing with the same total daily dose for the intervention group. Whereas, in the control group, the patients were continued with the once daily deferasirox dosing. Serum ferritin levels were tested at baseline and after 6 months of enrollment to assess the clinical outcome. Statistical analysis was performed using independent t test with the help of SPSS software version 22.

Results: Forty one patients were randomized into intervention (n=20) and control group(n=21). A statistically significant mean decrease in serum ferritin levels was detected in the intervention group (P value 0.011), while, the serum ferritin levels of the control group was significantly increased from baseline (P 0.000). The number of drug related problems was also significantly reduced in intervention group (P 0.031) when compared to control group (P 0.062).

Conclusions: This study concludes that twice daily dosing of deferasirox with the same total daily dose significantly enhances the iron chelation efficacy and tolerability among transfusion dependent paediatric beta thalassemia patients when compared to once daily regimen.

2419 | Endostar continuous versus intermittent intravenous infusion combined with chemotherapy in treating patients with advanced non-small cell lung cancer: A meta-analysis

Lu Xu[1], Bo Wang[2], Limai Mansai[2], Qihuan Li[2], Cheng Jin[2], Siyan Zhan[1,3] and Yi Ning[2]

[1]Peking University, Beijing, China; [2]Meinian Institute of Health, Beijing, China; [3]Research Center of Clinical Epidemiology, Beijing, China

Background: Endostar is a novel recombinant human endostatin approved to treat non-small cell lung cancer (NSCLC) in combination with first-line chemotherapy in China. Both intermittent intravenous (II) infusion and continuous intravenous (CI) infusion of Endostar are widely used currently in clinical practice.

Objectives: To compare the efficacy and safety of CI of Endostar with II.

Methods: We did a systematic review and meta-analysis by searching relevant databases from inception until June 25, 2019. Randomized controlled studies (RCTs), non-randomized controlled trials (NRCTs) and cohort studies compared CI of Endostar with II in combination with chemotherapy in stage III or IV NSCLC patients and reported efficacy or safety outcomes were eligible. Two reviewers independently screened records, extracted data and assessed risk of bias. Pooled risk ratios (RRs) with 95% confidence intervals were calculated using random effects meta-analysis for short-term efficacy and safety outcomes, and hazard ratios (HRs) for survival outcomes. GRADE approach was used to evaluate the quality of evidence in each outcome.

Results: Finally nine studies involving 597 patients were included, including two RCTs, three NRCTs and four cohort studies. For short-term efficacy, moderate quality of evidence showed that there were no significant differences between CI of Endostar and II in objective response rate (ORR; RR 1.34, 95% CI 0.91-1.98, P = 0.14) and disease control rate (DCR; RR 1.11, 95% CI 0.94-1.30, P = 0.21). Low quality of evidence indicated that CI of Endostar significantly improved both overall survival (OS; HR 0.69, 95% CI 0.48-0.99, P = 0.046) and progression-free survival (PFS; HR 0.71, 95% CI 0.55-0.93, P = 0.01) compared with II. As for safety outcomes, high quality evidence found that CI of Endostar significantly substantially reduced the risk of myelosuppression (RR 0.55, 95% CI 0.32-0.96, P = 0.03) and cardiovascular toxicity (RR 0.21, 95% CI 0.06-0.78, P = 0.02) in comparison

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with II. Low quality of evidence also supported reduced risk of laryngeal hemorrhage in CI compared with II. No significant differences were found for the other adverse events.

Conclusions: In NSCLC patients, compared with II, CI of Endostar had similar short-term efficacy, substantially lower risk of myelosuppression and cardiovascular toxicity. Although insufficient evidence supported the survival benefit of CI compared with II, large RCTs with long follow-up are needed to demonstrate these survival benefits.

2420 | Effects of incretin-based therapies on weight-related indicators among patients with type 2 diabetes: A network meta-analysis

Lu Xu[1], Shuqing Yu[1], Zhirong Yang[2], Sanbao Chai[3], Yuan Zhang[4], Feng Sun[1] and Siyan Zhan[1,5]

[1]Peking University, Beijing, China; [2]University of Cambridge, Cambridge, United Kingdom; [3]Peking University International Hospital, Beijing, China; [4]McMaster University, Hamilton, ON, Canada; [5]Research Center of Clinical Epidemiology, Beijing, China

Background: Nowadays, a new class of anti-diabetic drugs based on incretin including glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and dipeptidyl-peptidase IV inhibitors (DPP-4Is) have been introduced into clinical practice. Several studies reported that they can help control body weight.

Objectives: To evaluate the effects of incretin-based therapies on body weight, body mass index (BMI) and waist circumference (WC).

Methods: Databases including Medline, Embase, the Cochrane library and clinicaltrials.gov were searched for randomized controlled trials concerning the effects of incretin-based therapies on body weight, BMI and WC from inception to June 23, 2017. Risk of bias tool recommended by Cochrane handbook was used. Subgroup analysis, sensitivity analysis, and GRADE evaluation were performed as well.

Results: A total of 292 RCTs (262 for weight, 191 for BMI and 56 for WC) were included in this study. Nine treatments were involved in this study, including GLP-1 RAs, DPP-4Is, insulin, metformin (Met), sodium-dependent glucose transporters 2 (SGLT-2), sulfonylurea (SU), thiazolidinedione (TZD), α-glycosidase inhibitor (a-Glu) and placebo. A total of 227, 118, 183, 269 and 260 trials were at low risk in terms of random sequence generation, allocation concealment, blinding of outcome assessment, complete outcome data, and selective reporting. As for weight, compared with placebo, DPP-4Is increased weight slightly by 0.31kg (95% CI: 0.05, 0.58) and GLP-1 RAs decreased weight by -1.34kg (95% CI: -1.60, -1.09). As for BMI, GLP-1 RAs decreased BMI by -1.10 (95% CI: -1.42, -0.78) and DPP-4Is had negligible effects on BMI compared with placebo. As for WC, compared with placebo, GLP-1 RAs decreased WC by -1.28cm (95% CI: -1.69, -0.86) and DPP-4Is represented a neutral impact. Subgroup analysis showed that DPP-4Is have no statistically significant effect on reduction of all three indicators compared with placebo, but GLP-1 RAs lowered all three indicators. According to the sensitivity analysis, the main results were robust. According to the ranking results, GLP-1 RAs and DPP-4Is ranked second and sixth respectively in terms of effects on weight loss. Regarding BMI deduction, GLP-1 RAs and DPP-4Is ranked first and fourth respectively. Speaking of WC decrease, GLP-1 RAs and DPP-4Is ranked second and fourth respectively. The evidence quality of ranking of treatments were low, very low and moderate for weight, BMI and WC, respectively.

Conclusions: GLP-1 RAs are better at lowering all three indicators than DPP-4Is. Overall, the effects of GLP-1 RAs on weight, BMI and WC are good.

2432 | Comparative effectiveness of statins and fibrates for primary prevention of cardiovascular disease and mortality: A cohort study

Joseph E. Blais[1], Jiaxi Zhao[1], Stephen Weng[2], Eric Y.F. Yan[1], Vincent K.C. Yan[1], Michael Mok[3], Ian C.K. Wong[1,4] and Esther W. Chan[1]

[1]University of Hong Kong, Pokfulam, Hong Kong; [2]University of Nottingham, Nottingham, United Kingdom; [3]University Hospital Geelong, Geelong, Australia; [4]UCL School of Pharmacy, London, United Kingdom

Background: The role of fibrates and their comparative effectiveness to statins for primary prevention of cardiovascular disease and mortality remains uncertain.

Objectives: To determine whether statins versus fibrates are associated with a reduced risk of mortality and cardiovascular events in individuals without a history of cardiovascular disease.

Methods: Observational, active comparator, new user, cohort study, using the Clinical Data Analysis and Reporting System of the Hong Kong Hospital Authority. Adults without a history of cardiovascular disease who initiated a statin or a fibrate were enrolled from 2003-2012 and followed-up until the first occurrence of an outcome of interest, death, or 31 December 2017. Outcome measures were all-cause mortality, cardiovascular mortality, and major cardiovascular events, defined as a composite of cardiovascular mortality, myocardial infarction, stroke and transient ischemic attack. Cox-proportional hazards models, with inverse probability of treatment weighting on the estimated propensity score were used to estimate hazard ratios (HR). We performed subgroup analyses stratified by baseline low-density lipoprotein cholesterol concentration, high-density lipoprotein cholesterol concentration, triglyceride level, and diabetes status.

Results: A total of 271 491 participants (mean age 62; 46% men; median follow-up 7.3 years) were treated with a statin (n=213 218) or a fibrate (n=58 273). Compared with fibrates, statins were associated with a reduction in all-cause mortality (HR 0.96, 95% confidence interval (CI) 0.92-1.00), cardiovascular mortality (0.84, 95% CI 0.77-0.92), and major cardiovascular events (0.87, 95% CI 0.83-0.91). With the exception of participants with low high-density lipoprotein cholesterol concentrations (<1.0 mmol/L), statin use was consistently associated with a decreased risk of cardiovascular mortality and major cardiovascular events across subgroups.

Conclusions: Statins were more effective than fibrates at reducing major cardiovascular events and cardiovascular mortality in

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

participants without cardiovascular disease. Our results suggest that statins are preferred as initial treatment in individuals with elevated triglyceride levels or diabetes. However, individuals with low HDL cholesterol concentrations appeared to derive similar benefits from statins and fibrates.

2437 | Sodium-glucose cotransporter-2 inhibitors and the risk of gout - A Danish nationwide symmetry analysis and active comparator new user cohort study

Lars Christian Lund, Kasper Kristensen, Jesper Hallas and Daniel P Henriksen
University of Southern Denmark, Odense, Denmark

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are used as second-line treatment in type 2 diabetes. Recently, they have been associated with lower rates of gout compared to glucagon-like peptide-1 receptor agonists (GLP1-RA).
Objectives: To assess the association of SGLT2i and gout using a case-only study design and a cohort study design. In both designs we used GLP1-RA as an active comparator.
Methods: We used the symmetry analysis (SA) design and an active comparator, new user cohort study design. The SA is easy-to-compute and comprehend, and its greatest strength is the ability to adjust for time-invariant confounders. For the SA, we identified all Danish adults born before 1977 who filled their first prescription of an SGLT2i in the period 2012-2018 and had gout one year prior to or after this date. We repeated the analysis using GLP1-RA. The primary outcome measure was the trend adjusted sequence ratio (SR), which is an estimate of the incidence rate ratio (IRR). The active-comparator adjusted SR for SGLT2i emerged as the ratio of SRs for SGLT2 and GLP1-RA.
In the cohort study, new users of SGLT2i and GLP1-RA were matched in a 1:1 ratio based on a high dimensional propensity score. Individuals were followed according to the intention-to-treat and unadjusted IRRs, incidence rate differences (IRD) and numbers needed to treat for one additional patient to be harmed (NNTH) were obtained.
Results: A total of 208 individuals filled in their first prescription of an SGLT2i and had gout within the time window; 87 patients filled their prescription of SGLT2i prior to gout. The null-effect adjusted SR was 0.70 (95% CI 0.54-0.93). The corresponding SR of the GLP1-RA was 0.96 (0.83-1.07). SRs were effectively unchanged when varying window size (one year and five years). were effectively unchanged when varying window size (one year and five years).
The active comparator-adjusted SR was 0.73, (CI 0.54-0.98)
In the cohort analysis, 28,194 individuals were included contributing 41,576 person years and 264 incident cases of gout. Using GLP1-RA as an active comparator, the IRR was 0.47 (95% CI: 0.36-0.61), corresponding to an IRD of -4.6 cases/1000 person years and a NNTH of 215.
Conclusions: SGLT2 inhibitor use is associated with a decreased risk of gout compared to GLP-1 receptor agonists. This finding is robust towards the choice of study design.

2449 | Comparative effectiveness and safety of systemic treatments for metastatic castration-sensitive prostate cancer: A parametric survival network meta-analysis of randomized controlled trials

Lin Wang[1], Channing Paller[2], Hwanhee Hong[3], Anthony De Felice[2], Otis Brawley[2] and Caleb Alexander[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Johns Hopkins School of Medicine, Baltimore, MD;* [3]*Duke University, Baltimore, MD*

Background: Treatment decision-making for metastatic castration-sensitive prostate cancer (mCSPC) is complicated by the unclear comparative effectiveness and widely varying costs of competing strategies.
Objectives: To compare the effectiveness and safety of systemic treatments for mCSPC.
Methods: We searched bibliographic databases, regulatory documents, and trial registries for randomized controlled trials testing active drugs added to androgen deprivation therapy (ADT) for mCSPC. We used Cochrane risk-of-bias tool (version 2) to assess trial quality and Bayesian network meta-analysis (NMA) to estimate the relative effects of competing treatments. In addition to combing published time-invariant hazard ratios (HRs), we reconstructed survival data from Kaplan Meier curves to enable parametric survival NMA that allows time-varying HR.
Results: Seven trials with 7,236 patients were included comparing six treatments. Risk of bias is a concern for trials with open label (N=4), missing data (N=3), or unprespecified analysis (N=3). Ordered from the most to the least effective based on hazard ratios (HRs, 95% credible interval [CI]), treatments significantly improving overall survival (OS) include abiraterone acetate (0.62 [0.54-0.71]), apalutamide (0.67 [0.51-0.88]), and docetaxel (0.80 [0.71-0.89]); treatments significantly improving radiographic progression-free survival (rPFS) include enzalutamide (0.39 [0.30-0.51]), abiraterone (0.45 [0.40-0.51]), apalutamide (0.48 [0.39-0.59]), and docetaxel (0.68 [0.61-0.75]). Allowing time-varying HR produced similar treatment rankings. Serious adverse events (SAE) were substantially increased for docetaxel (odds ratio [OR] 104.17, 95% credible interval [CI] 24.85-1012.32) and slightly increased for abiraterone (OR 1.42, 95% CI 1.11-1.83).
Conclusions: Abiraterone provided the largest OS benefit with slightly increased risk of SAE. Apalutamide offered comparable OS benefit with abiraterone without increasing SAE risk. Although enzalutamide delayed rPFS to the greatest extent, longer follow-up is needed to examine its OS benefit.

2453 | Sodium-glucose cotransporter-2 inhibitors and risk of urolithiasis in patients with type 2 diabetes: A population-based active comparator new user cohort study

Kasper Bruun Kristensen, Daniel Pilsgaard Henriksen, Jesper Hallas and Lars Christian Lund
University of Southern Denmark, Odense, Denmark

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Sodium-Glucose Cotransporter-2 Inhibitors (SGLT2i) lower blood glucose levels by increasing urinary glucose secretion. This increases urine osmolality and urinary flow, which reduces the concentration of lithogenic substances and, theoretically, the risk of forming stones in the urinary tract (urolithiasis). Whether this proposed mechanism translates into a clinically relevant reduction of urolithiasis risk is unknown.

Objectives: To examine whether initiation of SGLT2i was associated with a decreased rate of urolithiasis compared to Glucagon-Like-Peptide-1 analogues (GLP-1).

Methods: An active comparator new user cohort study was conducted using the nationwide Danish health registries. We identified all patients without a history of urolithiasis who initiated either SGLT2i or GLP-1 therapy from 2012 and onwards. Patients were followed for 3 years or until death, emigration, urolithiasis, or end of the study period (12-31-2018). High-dimensional propensity scores were calculated and asymmetrical trimming of the propensity score was conducted. Remaining SGLT2i and GLP-1 initiators were matched 1:1 based on the propensity score. We calculated incidence rates and incidence rate ratios with 95% confidence intervals (CI) using an intention-to-treat analysis where patients were considered exposed from cohort entry throughout follow-up.

Results: Results: We included 14,819 new users of SGLT2is and 14,819 new users of GLP-1s after propensity score matching. The median age was 61 years, 48% were female and the mean duration of follow-up was 1.8 years. The incidence rate of urolithiasis was lower in the SGLT-2 cohort (2.6 per 1000 person-years) compared to the GLP-1 cohort (4.5 per 1000 person-years) with an incidence rate ratio of 0.58 (95% CI 0.42 to 0.78) and a rate difference of -1.9 per 1000 person years (95% CI -0.9 to -2.9). Number needed to treat for one year was 533 (95% CI 347 to 1149).

Conclusions: Conclusion: Patients who initiated SGLT-2 inhibitors had an approximately 40% lower risk of developing urolithiasis compared to patients initiating GLP-1 agonists. There are plausible mechanisms through which SGLT2 inhibitors may reduce stone formation in the urinary tract, however, the clinical relevance of this finding is probably limited due to the small absolute risk reduction.

2500 | Comparative effectiveness and safety of SGLT2 inhibitors vs GLP-1 receptor agonists among real-world older adult

Elisabetta Patorno[1], Ajinkya Pawar[1], Lily G. Bessette[1], Dae H. Kim[1], Chintan Dave[2], Robert J. Glynn[1], Medha N. Munshi[3], Sebastian Schneeweiss[1], Deborah J. Wexler[4] and Seoyoung C. Kim[1]

[1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Rutgers University, New Brunswick, NJ; [3]Beth Israel Deaconess Medical Center and Joslin Diabetes Center, Harvard Medical School, Boston, MA; [4]Massachusetts General Hospital Diabetes Center and Harvard Medical School, Boston, MA

Background: Both SGLT2 inhibitors (SGLT2i) and GLP-1 receptor agonists (GLP-1RA) have shown cardiovascular benefits in randomized controlled trials of patients with type 2 diabetes (T2D) generally younger than 65 years and mostly with cardiovascular disease (CVD). However, the comparative effectiveness and safety of these agents in older adults, who represent most of patients with T2D, remain largely unknown.

Objectives: To evaluate the comparative effectiveness and safety of SGLT2i vs. GLP-1RA in real-world older adults.

Methods: Using U.S. Medicare claims data (4/2013-12/2016), we identified 45,047 pairs of 1:1 propensity score (PS)-matched T2D patients ≥66 years initiating SGLT2i or GLP-1RA. Primary outcomes included major adverse cardiovascular events (MACE, i.e., myocardial infarction, stroke or cardiovascular death) and hospitalization for heart failure (HHF). Individual MACE components and overall mortality were secondary effectiveness outcomes. Safety outcomes were diabetic ketoacidosis (DKA), genital infections (GI), fractures, lower-limb amputations (LLA), acute kidney injury (AKI), and severe urinary tract infections (UTI). Subgroup analyses by baseline CVD were conducted for effectiveness outcomes. We estimated hazard ratios (HR) and rate differences (RD) per 1000 person-years, each with 95% confidence intervals (CI), controlling for 140 baseline covariates.

Results: Compared with PS-matched GLP-1RA initiators, PS-matched SGLT2i initiators had a similar risk of MACE [HR (95% CI)=0.98 (0.87-1.10); RD (95% CI)= -0.38 (-2.48, 1.72)] and a decreased risk of HHF [HR=0.68 (0.57-0.80)]; RD= -3.23 (-4.68, -1.77)], over a mean 8.4-month follow-up. The risk of the individual MACE components and overall mortality was similar between groups. SGLT2i initiators had 0.7 more DKA, 0.9 more LLA, 57.1 more GI, and 5.6 fewer AKI events, vs. GLP-1RA (each $p<0.05$). Among patients with baseline CVD, SGLT2i vs. GLP-1RA initiators had no reduction in MACE but 5.9 fewer HHF, 2.6 fewer cardiovascular deaths and 2.8 fewer overall deaths (each $p<0.05$). Among those without CVD, SGLT2i vs. GLP-1RA initiators had no reduction in MACE, its components, or overall mortality, but had reduced risk of HHF (1.1 fewer events, $p<0.05$), with a benefit of substantially lower magnitude compared to patients with CVD (p for homogeneity<0.001).

Conclusions: Among real-world older adults, SGLT2i had similar risk of MACE, decreased risk of HHF, and increased risk of DKA, LLA, and GI, vs. GLP-1RA. In patients with CVD, SGLT2i had a more favorable risk-benefit profile vs. GLP-1RA, with less benefit in those without CVD.

2554 | Systematic evaluation of the efficacy-effectiveness gap of systemic treatments in extensive disease small cell lung cancer

Christine Cramer[1], Franz Schramel[2], Bas Peters[2], John van Putten[3], Olaf Klungel[4], Harry Groen[5] and Ewoudt van de Garde[4]

[1]Santeon, Utrecht, Netherlands; [2]St. Antonius Hospital, Nieuwegein, Netherlands; [3]Martini Hospital, Groningen, Netherlands; [4]Utrecht University, Utrecht, Netherlands; [5]University Medical Center Groningen, Groningen, Netherlands

Background: The recommendations in treatment standards are conventionally based on clinical trial data, in which patient populations

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

are studied that are not necessarily a reflection of the general population seen in clinical practice. Important patient characteristics predictive for treatment response are often underrepresented in clinical trial populations.

Objectives: The aim of this study is to assess how clinical outcomes in real-world (effectiveness) correspond to the outcomes in clinical trials (efficacy) of systemic treatments for ED SCLC, and to search for patient factors that may explain a gap.

Methods: All patients diagnosed with ED SCLC between 2008 and 2014 in six Dutch large teaching hospitals (Santeon network) were identified and followed-up from date of diagnosis until death or end of data collection. For every patient, an efficacy-effectiveness factor (EE factor) was calculated by dividing individual patients' overall survival (OS) by the pooled median OS assessed from clinical trials with the respective first-line treatment. A multivariable linear regression analysis was applied to study the association between patient and treatment characteristics and the magnitude of the efficacy-effectiveness gap.

Results: From 792 diagnosed patients, 568 (72%) started with first-line treatment. For all studied regimens (carboplatin-etoposide, cisplatin-etoposide, and cyclophosphamide-doxorubicin-etoposide), the median OS in real-world is shorter than the clinical trial reference median OS. Overall, the median EE factor was 0.79 ($p<0.001$ from 1.00). Poor performance status (ECOG≥2) and a higher age at diagnosis (age≥65 years) were independent predictors for a lower EE factor. The EE gap was 43% in patients with both age ≥65 years and ECOG ≥2 (EE factor 0.57). The mean age and the proportion of patients with ECOG≥2 in real-world were different from those in clinical trials (mean age of 66 versus 62 years, and ECOG≥2 25% versus 17%; both $p<0.001$). In patients with ECOG≥2 and aged ≥65 years in real-world, early discontinuation of treatment and no subsequent line of treatment were more prevalent.

Conclusions: Overall survival of patients with ED SCLC treated with systemic therapy in real-world practice is 21% shorter than for patients included in trials. Differences in age at diagnosis and performance status explain this gap.

2566 | The effect of the indicated use of β-blockers on the risk of exacerbations in chronic obstructive pulmonary disease: The Rotterdam study

Leila Karimi[1], Guy Brusselle[2,3,4], Lies Lahousse[3,5], Phebe De Nocker[5], Bruno H. Stricker[3,6] and Katia M.C. Verhamme[1,5]

[1]Department of Medical Informatics, Erasmus University Medical Center, Rotterdam, Netherlands; [2]Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; [3]Department of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands; [4]Department of Respiratory Medicine, Erasmus University Medical Center, Rotterdam, Netherlands; [5]Department of Bioanalysis, Ghent University, Ghent, Belgium; [6]Department of Internal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands

Background: While several observational studies have reported a reduced risk of exacerbations in COPD patients treated with β-blockers (BB), physicians are reluctant to prescribe BB in patients with cardiovascular disease and concomitant COPD. Recently, the BLOCK COPD randomized clinical trial (RCT) reported an increased risk of COPD exacerbations in metoprolol treated COPD patients without an indication for the use of BB. The current discrepancy between findings of observational studies and the BLOCK COPD RCT might result in further reduction of prescribing BB in COPD patients with a cardiac indication.

Objectives: We investigated whether the association between use of BB and risk of COPD exacerbations differed between patients with and without an indication for treatment with BB.

Methods: Within the Rotterdam Study, a prospective population-based cohort study, we followed COPD subjects until the first COPD exacerbation or end of follow-up. COPD exacerbations were defined as acute episodes of worsening of respiratory symptoms requiring systemic corticosteroids and/or antibiotics or hospitalization. Individuals were considered to have an indication for treatment with BB in case of having hypertension, coronary heart disease, atrial fibrillation, or heart failure at baseline. The association between BB use, as a time-varying variable, and COPD exacerbations was assessed using Cox proportional hazards models adjusted for age, sex, smoking, incident cardiovascular disease (i.e., heart failure, hypertension, atrial fibrillation, and coronary heart disease) during follow-up, respiratory drugs, and nitrates.

Results: In total 1,312 COPD patients with a mean age=69.7±9.2 were included. In patients with an indication for treatment with BB (n=755, mean age=70.4±8.8), current use of cardioselective BB was significantly associated with a reduced risk of COPD exacerbations (Hazard Ratio (HR)=0.69, 95% Confidence Interval (CI): 0.57-0.85). In contrast, in subjects without an indication for treatment with BB (n=557, mean age=68.8±9.7), use of cardioselective BB was not associated with an altered risk of COPD exacerbations (HR=0.94, 95% CI: 0.55-1.62).

Conclusions: In the Rotterdam Study, use of cardioselective BB reduced the risk of exacerbations only in COPD patients with concomitant cardiovascular disease. Our results could explain the discordant findings between the BLOCK COPD RCT (excluding patients with a therapeutic indication for the use of BB) and previous observational studies.

2592 | Effectiveness and safety of vitamin K antagonists in patients with non-valvular atrial fibrillation and renal disease: A cohort study

Antonios Douros[1,2,3], Julien Rousseau[1], Christopher Filliter[4], Brenda Hemmelgarn[5], Samy Suissa[1,2] and Christel Renoux[2,6]

[1]Department of Medicine, McGill University, Montreal, QC, Canada; [2]Department of Epidemiology, McGill University, Montreal, QC, Canada; [3]Charité – Universitätsmedizin Berlin, Berlin, Germany; [4]Lady Davis Institute, Montreal, QC, Canada; [5]University of Alberta, Edmonton, AB, Canada; [6]Department of Neurology, McGill University, Montreal, QC, Canada

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Patients with non-valvular atrial fibrillation (NVAF) and renal impairment are at high risk of both thrombosis and bleeding complicating antithrombotic treatment. However, available clinical evidence on benefits and risks of antithrombotic drugs commonly used in this setting such as vitamin K antagonists (VKAs) or antiplatelet agents is scarce.

Objectives: To assess the effectiveness and safety of VKAs compared to antiplatelet agents in NVAF patients with chronic kidney disease (CKD) or undergoing dialysis.

Methods: We conducted a population-based cohort study using linked administrative healthcare databases from Quebec. We assembled a cohort of patients with incident NVAF from 2000 to 2014 and then constructed three subcohorts based on renal status (dialysis, CKD, no renal disease) at cohort entry. Using a nested case-control approach, we identified all cases with a first-ever diagnosis of ischemic stroke, major bleeding or all-cause mortality (depending on the outcome under study) during follow-up and matched them to 30 controls on age, sex, date of cohort entry, and duration of follow-up in each subcohort. We estimated incidence rate ratios (RRs) and 95% confidence intervals (CIs) of each outcome associated with current use of VKAs compared with current use of antiplatelet agents using conditional logistic regression. Sensitivity analyses accounted for possible exposure and outcome misclassification, restricted to patients with high baseline ischemic or bleeding risk, and explored the potential impact of reverse causality.

Results: Of 231,411 patients with NVAF, 3,613 were undergoing dialysis and 30,608 had CKD. Among dialysis patients, VKAs were associated with a numerically decreased risk of ischemic stroke (RR, 0.79; 95% CI, 0.46 to 1.36), an increased risk of major bleeding (RR, 1.42; 95% CI, 1.04 to 1.93), and a similar risk of all-cause mortality (RR, 0.98; 95% CI, 0.81 to 1.20), compared with antiplatelet agents. Among CKD patients, there was a decreased risk of ischemic stroke (RR, 0.64; 95% CI, 0.56 to 0.73), an increased risk of major bleeding (RR, 1.47; 95% CI, 1.35 to 1.59), and a decreased risk of all-cause mortality (RR, 0.86; 95% CI, 0.81 to 0.90). Sensitivity analyses yielded highly consistent results.

Conclusions: Our results suggest that VKAs could decrease the risk of ischemic stroke in NVAF patients with CKD or undergoing dialysis at the cost of a higher risk of major bleeding. Until data from randomized trials are available, individualized benefit-risk assessment for the antithrombotic management of these vulnerable populations is required.

2638 | Cardiovascular safety of sulfonylureas in type 2 diabetes: Effect modification by obesity?

Karine Suissa[1], Antonios Douros[2], Laurent Azoulay[2], Kristian B. Filion[2] and Sebastian Schneeweiss[1]

[1]*Brigham and Women's Hospital and Harvard Medical School, Boston, MA;* [2]*Jewish General Hospital, Montreal, QC, Canada*

Background: Pharmacokinetic studies suggest that adiposity may modify antidiabetic medication efficacy and safety via altered drug distribution and clearance. While sulfonylureas have been linked to a higher cardiovascular (CV) risk, with inconsistent results, the role of obesity remains unclear.

Objectives: Our main objective was to evaluate the effect of obesity on CV risk with sulfonylureas as first-line therapies for type 2 diabetes in a clinical practice.

Methods: Using the UK's Clinical Practice Research Datalink, we conducted a cohort study of patients initiating antidiabetic treatment. Initiators of sulfonylureas monotherapy were matched with initiators of metformin monotherapy on a high-dimensional propensity score. Patients were censored at the time of discontinuation or addition of another antidiabetic drug. We used Cox proportional hazards models within BMI categories (< 25 kg/m^2 (normal weight; 26%), 25-30 kg/m^2 (overweight; 42%), ≥ 30 kg/m^2 obese; 32%)) to estimate hazard ratios (HR) of major adverse cardiovascular events (MACE), individual components of MACE, and all-cause mortality, comparing sulfonylureas with metformin.

Results: The initial cohort included 94,750 patients with type 2 diabetes initiating sulfonylureas or metformin. We matched 13,999 initiators of sulfonylureas to an equal number of metformin initiators. The overall HR of MACE comparing sulfonylureas with metformin was 1.23 (95% CI: 1.08-1.39); the HR was 1.33 (95% CI: 1.02-1.74) among obese patients, 1.27 (95% CI: 1.04-1.55) for overweight patients, and 0.99 (95% CI: 0.77-1.28) among normal weight patients. Similarly, the risk of all-cause mortality, CV death and ischemic stroke with sulfonylureas was highest in obese individuals, with evidence of interactions for all-cause mortality (p-interaction: <0.0001) and stroke (p-interaction: 0.05).

Conclusions: Sulfonylureas as a first-line monotherapy for type 2 diabetes is associated with a higher risk of MACE compared with metformin. Our data suggest that this effect might be strongest in obese patients, with no increased risk in normal weight patients. To ensure the best response to treatment, BMI level may be considered when choosing metformin over sulfonylureas for first-line treatment.

3749 | Comparative effectiveness of biologics and targeted therapies for psoriatic arthritis

Hanzhe Zhang[1], Jiajun Wen[1], G. Caleb Alexander[1] and Jeffrey R. Curtis[2]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*University of Alabama at Birmingham, Birmingham, AL*

Objectives: To quantify comparative effectiveness of interleukin (IL)-12/23 antagonist (ustekinumab), IL-17A antagonists (secukinumab and ixekizumab), PDE4 inhibitor (apremilast), and tumor necrosis factor-alpha (TNF-α) inhibitors (infliximab, etanercept, adalimumab, certolizumab pegol, and golimumab) for psoriatic arthritis (PsA).

Methods: We adapted a de-identified claims-based algorithm validated for inflammatory arthritis treatments to compare treatments among a retrospective cohort of commercially insured and Medicare Advantage beneficiaries with PsA from October 2013 through April 2019 in the OptumLabs® Data Warehouse. Main outcomes include

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(1) Treatment effectiveness, based on: adherence, adding or switching biologic or PDE4, addition of new nonbiologic DMARD, increase in biologic or PDE4 dose or frequency, and glucocorticoid use; (2) percentage of each group fulfilling the effectiveness algorithm. We used Poisson regression with robust variance stratified by prior PsA biologic exposure and adjusted for potential confounders.

Results: Of 2797 individuals with PsA, 334 received IL-12/23, 140 IL-17A's, 634 PDE4 and 1689 TNF-α's. Effectiveness criteria were fulfilled among 63 (18.9%) IL-12/23 recipients, 40 (28.6%) IL-17A recipients, 161 (25.4%) PDE4 recipients, and 545 (32.3%) TNF-α recipients. Among biologic naïve individuals, IL-12/23 was less effective than TNF-α's with fully adjusted relative risk [RR] compared to TNF-α's of 0.61 (95% confidence intervals [CI] 0.43, 0.86). Among biologic experienced individuals, PDE4 recipients were less effective than TNF-α's (adjusted RR 0.66, CI 0.46, 0.94).

Conclusions: TNF-α's appeared more effective than IL-12/23's for biologic naïve individuals, and PDE4's for biologic experienced individuals. These results may help inform treatment choice for individuals with psoriatic arthritis.

3757 | Comparative effectiveness of antipsychotics for risk of attempted or completed suicide among persons with schizophrenia

Heidi Taipale[1], Markku Lähteenvuo[1], Antti Tanskanen[1], Ellenor Mittendorfer-Rutz[2] and Jari Tiihonen[2]

[1]*University of Eastern Finland, Kuopio, Finland;* [2]*Karolinska Institutet, Stockholm, Sweden*

Background: Very little is known about effectiveness of antipsychotics for preventing suicide attempts and completed suicides among patients with schizophrenia.

Objectives: The aim of this study was to investigate comparative effectiveness of antipsychotics for risk of attempted or completed suicide among all patients with schizophrenia in Finland and Sweden.

Methods: Two retrospective nationwide register-based cohort studies were conducted, including all individuals with schizophrenia in Finland (N=61889) and Sweden (N=29823). The main exposure was ten most commonly used antipsychotic monotherapies, and also adjunctive pharmacotherapies including antidepressants, mood stabilizers, benzodiazepines and Z-drugs were investigated. The main outcome measure was attempted or completed suicide which was analyzed with within-individual models by comparing use and non-use periods in the same individual in stratified Cox regression models to minimize selection bias. Sensitivity analyses were conducted by between models, with attempted suicide (hospitalization only) as an outcome, and by censoring the first 30 days from each exposure.

Results: Compared with no use of antipsychotics, clozapine use was the only antipsychotic consistently associated with a decreased risk of suicidal outcomes. Hazard ratios (HRs) and 95% confidence intervals for attempted or completed suicide in clozapine use were 0.64 (0.49-0.84) in the Finnish cohort and 0.66 (0.43-0.99) in the Swedish cohort. No other antipsychotic was associated with a reduced risk of attempted and/or completed suicide. Benzodiazepines and Z-drugs were associated with an increased risk of attempted or completed suicide (HRs 1.29-1.30 for benzodiazepines and 1.33-1.62 for Z-drugs).

Conclusions: Clozapine was the only antipsychotic associated with decreased risk of attempted or completed suicide among patients with schizophrenia, and it should be considered as first-line treatment for high-risk patients.

3764 | Evaluation on therapeutic equivalence of generic and brand-name clopidogrel

Ju-Ling Chen[1,2], Ching-Lan Cheng[1,2] and Yea-Huei Kao Yang[1]

[1]*Institute of Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan;* [2]*Department of Pharmacy, National Cheng Kung University Hospital, Tainan, Taiwan*

Background: As the increasingly use of generic drugs, concerns about their therapeutic equivalence remain. Because it is unlikely to employ clinical trials to assess therapeutic equivalence between generic and brand-name drugs, claims database and electronic medical records (EMR) are compiled routinely from clinical practice, thus can be used to establish the real-world-evidence in this regard. Meanwhile, persistence and clinical outcomes can be measured with explicit algorithm to assess therapeutic equivalence.

Objectives: To evaluate the therapeutic equivalence of generic and brand clopidogrel.

Methods: A retrospective cohort study with new user design was conducted by using the cohort consisted of two-million peoples, who were randomly sampled from Taiwan National Health Insurance Database (NHID). Patients who were newly hospitalized with an acute coronary syndrome (ACS) from 2008 to 2015, survived at least 7 days after ACS and newly prescribed clopidogrel were eligible for inclusion. Patients were grouped to generic or brand clopidogrel users. The clinical outcome was a composite of recurrent ACS hospitalization, emergency room revascularization and death at 1 year. The non-persistence was defined as an event of treatment change, which included discontinuation, switching study drug to another anti-platelet medication. We followed up patients who incurred treatment change, or up to 9 months, whichever came first. We also conducted sensitivity analysis based on receiving percutaneous coronary intervention (PCI) or not to eliminate confounding by ACS severity. Propensity score (PS) was performed for matching and Cox proportional hazards regression was used to calculate hazard ratios and confidence interval.

Results: There were 7,499 brand and 438 generic users met study criteria. The mean age was 64 years old and hypertension was the most frequent comorbidity among two groups. Compared to brand users, the adjusted hazard ratio for clinical outcome and persistence in generic users were 1.13 [95% CI: 0.9-1.43] and 0.91 [95% CI: 0.8-1.4], respectively. The result from sensitivity analysis was consistent with primary result, implying no significant difference of clinical outcome and treatment change between generic and brand users (HR 1.10 [0.76-1.58], HR 0.98 [0.80-1.20], respectively.)

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: The findings indicate that generic and brand clopidogrel are therapeutic equivalent.

3767 | Early real-world experience with CD19-directed chimeric antigen receptor T-cell therapy (CAR T) among patients with diffuse large B-cell lymphoma (DLBCL)

Jessica J. Jalbert[1], Jon E. Arnason[2], Wenzhen Ge[1], Chieh-I Chen[1], Srikanth Ambati[1], Ning Wu[1] and Aafia Chaudhry[1]

[1]*Regeneron Pharmaceuticals, Inc., Tarrytown, NY;* [2]*Beth Israel Deaconess Medical Center, Boston, MA*

Background: CAR T, approved in the US as of October 2017, impacted the treatment landscape for patients with relapsed or refractory (R/R) DLBCL after ≥2 lines of therapy, but there is little known about real-world (RW) treatment patterns in patients who fail or do not respond to CAR T. No treatments of proven benefits are available after CAR T treatment failure.

Objectives: The objective of this study was to describe RW treatment patterns after CAR T.

Methods: From MarketScan Commercial/Medicare claims databases (2017–2018), we identified adult DLBCL patients who received approved CD19-directed CAR T (treatment date = index date). Eligible patients had ≥6 months continuous health plan enrollment prior to index date (i.e. baseline period) and were followed until plan disenrollment or December 31, 2018. Patients with a diagnosis of acute lymphoblastic leukemia over the baseline period were excluded. We identified the first and second treatments after CAR T with systemic chemotherapy, targeted therapy, immunotherapy, hematopoietic stem cell transplant (SCT), radiation therapy (RT), or a second round of CAR T therapy. Kaplan-Meier estimators were used to estimate risk of subsequent treatment and time to next treatment.

Results: We identified 56 patients with DLBCL treated with CAR T (mean age [SD]: 57.3 years [9.9]; 23.2% female; 80.4% commercially insured). All patients received CAR T in the inpatient setting, median (Q1–Q3) length of stay was 15 days (12–19). Out of 56 patients, 19 initiated a treatment following CAR T; risk of subsequent treatment at 6 months post index was 45.6% (95% CI: 25.4–60.4%) and median days from CAR T to subsequent treatment was 233 days (95% CI: 139–NA). Out of 19 patients, 3 initiated a second treatment following CAR T, within 8–69 days of the first treatment. Over a median (Q1–Q3) follow-up of 139.5 days (90.5–194) following CAR T, of the 19 patients treated after CAR T, 57.9% were treated with immunotherapy, 36.8% with RT, 26.3% with targeted therapy, 21.1% with SCT, 15.8% with chemotherapy, and 0% with a second round of CAR T therapy.

Conclusions: There are few multicenter studies reporting RW treatment patterns in patients who received CAR T. In this study, risk of subsequent treatment at 6 months following CAR T in a RW setting was almost 50%. Although limited by duration of follow-up, our results suggest that additional, effective salvage treatment strategies are needed for patients who do not respond to CAR T or do not achieve a durable response to CAR T.

3773 | Comparing stroke prevention therapy of direct oral anticoagulants and vitamin-K-antagonists in patients with atrial fibrillation: A nationwide retrospective observational study

Lena M. Paschke[1], Maike Schulz[1], Kerstin Klimke[1], Attila Altiner[2] and Dominik von Stillfried[1]

[1]*Central Research Institute of Ambulatory Health Care in Germany, Berlin, Germany;* [2]*University of Rostock, Berlin, Germany*

Background: Direct oral anticoagulants (DOACs) are not only increasingly being used for the initial stroke prevention therapy but progressively also substitute VKA treatment in patients with non-valvular atrial fibrillation (AF). DOACs have been compared regarding therapeutic efficacy and adverse outcomes to warfarin in several pivotal studies and showed non-inferiority in terms of stroke prevention and superiority in terms of bleeding complications. However, comprehensive comparative studies are lacking for phenprocoumon, a Vitamin-K-Antagonist (VKA) prescribed frequently outside the US and the UK and accounting for 99% of all VKA prescriptions in Germany. Patients treated with phenprocoumon seem to meet more often international normalized ratio values in the therapeutic range, which may have implications concerning their efficacy and safety. This study aims at comparing the risk of stroke and bleeding in phenprocoumon and DOAC-treated patients with AF in an adequately powered observational study population.

Objectives: This study aims at comparing the risk of stroke and bleeding in phenprocoumon and DOAC-treated patients with AF in an adequately powered observational study population.

Methods: Retrospective analysis of stroke and bleeding incidence of 834.000 patients (1.27 million patient-years) treated with DOAC or VKA for stroke prevention in German ambulatory care between 2010 and 2017.

Results: Patients treated with DOAC had an overall higher risk for stroke (HR: 1.32; 95%CI: 1.29-1.35) and a lower risk for bleeding (0.89; 0.88-0.90) compared to VKA. When analyzed separately the risk for stroke was higher for dabigatran (1.93; 1.82-2.03), apixaban (1.52; 1.46-1.58) and rivaroxaban (1.13; 1.10-1.17) but not for edoxaban (0.88; 0.74-1.05). The risk for bleeding was lower for dabigatran (0.85; 0.83-0.88), apixaban (0.71; 0.70-0.73) and edoxaban (0.29; 0.17-0.51) but not for rivaroxaban (1.03; 1.01-1.04).

Conclusions: This study provides a comprehensive view of the stroke and bleeding risks associated with VKA and DOAC use in Germany. Phenprocoumon may be preferable to DOAC treatment for the prevention of strokes in AF in a real world population cared for in ambulatory care.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 3790 | Survival outcome in patients with metastatic castration-resistant prostate cancer according to first-line treatment

Nicolas H. Thurin[1], Magali Rouyer[1], Jérémy Jové[1], Marine Gross-Goupil[2], Thibaud Haaser[2], Xavier Rebillard[3], Michel Soulié[4], Gérard de Pouvourville[5], Marie Pierrès[6], Camille Capone[6], Stéphanie Lamarque[1], Emmanuelle Bignon[1], Cécile Droz-Perroteau[1], Nicholas Moore[1,2] and Patrick Blin[1]

[1]*Bordeaux PharmacoEpi, INSERM CIC 1401, Université de Bordeaux, Bordeaux, France;* [2]*CHU de Bordeaux, Bordeaux, France;* [3]*Clinique Beau Soleil, Montpellier, France;* [4]*CHU de Toulouse, Toulouse, France;* [5]*ESSEC, Cergy-Pontoise, France;* [6]*Janssen, Issy les Moulineaux, France*

Background: Therapeutic strategy in metastatic castration-resistant prostate cancer (mCRPC) has evolved significantly with the introduction of abiraterone acetate in association with prednisone/prednisolone in first-line treatment in December 2012.

Objectives: To compare the effectiveness of abiraterone acetate and docetaxel as first-line treatments for mCRPC, in real-life setting.

Methods: Patients with mCRPC were identified in the main scheme of the National Healthcare System database (SNDS), which covers about 86% of the French population, and capturing all reimbursed healthcare expenditures and hospital discharge summaries. Those initiating docetaxel or abiraterone acetate in 1st line in 2014 were included and 1:1 matched on the previous prostate cancer stage before mCRPC status, the delay from the date of initial diagnosis and a high-dimensional propensity score. The 36-month overall survival and the 36-month discontinuation-free survival (i.e. survival time until treatment switch or death) were compared using Cox proportional hazards risk model.

Results: In 2014, out of the 12 951 patients with prevalent mCRPC, 1 214 initiated docetaxel in 1st line and 2 444 initiated abiraterone. A total of 716 patients per group were matched with good comparability (C-statistic = 0.6). The median duration of docetaxel - defined as the time between the first and the last infusion - was 7.3 months with a median of 6 infusions. The median duration of abiraterone acetate - corresponding to the period covered by the dispensed drug - was 9.1 months. Near 70% of the docetaxel and 62% of the abiraterone acetate patients received a 2nd line of treatment. The 36-month overall survival probability were 27.9% (95% CI 25.0 - 31.2) for docetaxel and 34.6% (95% CI 31.5 - 38.1) for abiraterone acetate. The corresponding median survivals were respectively of 18.5 months (95% CI 17.1 - 20.7) and 25.5 months (95% CI 23.0 - 27.3). The 36-month discontinuation-free survival probability were 2.9% (95% CI 2.1 - 4.1) for docetaxel and 13.8% (95% CI 11.7 - 16.4) for abiraterone acetate. The corresponding median survivals were respectively of 7.4 months (95% CI 7.0 - 8.0) and 10.8 months (95% CI 10.1 - 11.7).

Conclusions: First-line treatment with abiraterone acetate in mCRPC patients results in a better 36-month overall survival and discontinuation-free survival compared to docetaxel in real-life setting.

3794 | Implementation of cluster randomisation of prescribing policy for studying comparative effectiveness: Experience from the pilot of the evidence study

Robert Flynn, Angela Flynn, Amy Rogers, Lewis McConnachie, Thomas MacDonald, Isla Mackenzie and Alexander Doney

University of Dundee, Dundee, United Kingdom

Background: The randomised policy design has potential to assess comparative effectiveness where data from head-to-head trials is lacking. In 2011, the UK NICE hypertension guideline included a recommendation that thiazide-like diuretics (indapamide - IND) be used in preference to thiazide diuretics (bendroflumethiazide - BND) for hypertension. There is sparse evidence backing this recommendation and BND remains widely used the UK. The EVIDENCE study randomises GP practices to use either IND or BND as their first line diuretic for hypertension. Medication is switched where necessary.

Objectives: To describe the procedure and assess the effectiveness of the drug switch at practices participating in EVIDENCE.

Methods: For each practice a list was created of patients on prescriptions for either IND or BND. Patients were excluded if they were <18 years, had received both drugs in the past or received them for reason other than hypertension. Clinicians from each practice reviewed the list to remove any not appropriate for switching and the practice formulary was then randomised to either IND or BND. Patients were sent a letter explaining that their practice was taking part in the study and stating if their diuretic would change. Drug changes were implemented by a clinical pharmacist within the practice. The effectiveness of the drug switch was assessed by measuring the amount of IND prescribed as a proportion of total IND and BND prescribing within each participating practice on a monthly basis using open-access practice-level prescribing data. Time series analysis was used to assess the impact of the drug switch for 36 monthly time point prior to and 10 months after the implementation date. Research Ethics Committee approval was obtained prior to starting the study.

Results: Of 29 pilot practices in 5 health board regions of Scotland, 14 were randomised to IND and 15 to BND. Of 5,985 patients sent letters 40.7% had their medication changed. Amongst practices randomised to BND, the proportion of IND prescribing prior to the switch was 20.0% (95% 16.3 to 24.3) and this dropped to 9.6% (7.6 to 12.0) then falling at -0.15% (-0.12 to -0.19) per month. For practices randomised to IND the proportion of prescriptions for IND was 16.4% (13.3 to 20.0) and increased to 81.7% (77.6 to 85.1) then decreasing slowly at -0.14% (-0.15 to -0.12) per month.

Conclusions: The implementation of the drug switch was effective and sustained in all GP practices participating in the study. Future work will focus on patient level analysis of data linking prescribing to end points and the roll out of a fully powered study.

3797 | Effectiveness and safety of direct oral anticoagulants in patients with cancer associated venous thromboembolism: A population based cohort study

Antonios Douros[1,2,3], Christopher Filliter[4], Laurent Azoulay[2,5] and Vicky Tagalakis[1]

[1]*Department of Medicine, McGill University, Montreal, QC, Canada;* [2]*Department of Epidemiology, McGill University, Montreal, QC, Canada;* [3]*Charité – Universitätsmedizin Berlin, Berlin, Germany;* [4]*Lady Davis Institute, Montreal, QC, Canada;* [5]*Department of Oncology, McGill University, Montreal, QC, Canada*

Background: Patients with cancer associated venous thromboembolism (VTE) are at high risk of recurrent VTE and bleeding. Recent randomized controlled trials suggested that direct oral anticoagulants (DOACs) may be more effective, but with an increased risk of major bleeding compared to standard of care low-molecular-weight heparin (LMWH). To date, real-world evidence on the effects of DOACs in patients with cancer associated VTE is scarce.

Objectives: To assess the effectiveness and safety of DOACs compared to LMWH in patients with cancer associated VTE.

Methods: We conducted a population based cohort study using linked administrative health care databases from Québec. We included patients with incident VTE from 2012 to 2015 and a cancer diagnosis in the year before the VTE. Date of cohort entry was defined as the date of the first dispensed prescription for an anticoagulant in the 30 days after the VTE. Using an active comparator new-user design with an as-treated exposure definition, we compared the use of DOACs with the use of LMWH. Cox proportional hazards models were used to estimate adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) of recurrent VTE (defined as outpatient or inpatient diagnosis of VTE complemented by a diagnostic procedure) and major bleeding (defined as hospitalization with bleeding or death due to bleeding). In secondary analyses we stratified by age (≥70 years versus <70 years) and sex.

Results: Our cohort comprised 4,911 patients with cancer associated VTE initiating treatment with anticoagulants. Of those, 562 patients initiated DOACs and 3090 initiated LMWH (the remaining 1259 initiated vitamin K antagonists). Compared with the use of LMWH, the use of DOACs was associated with a decreased risk of recurrent VTE (HR, 0.52; 95% CI, 0.37 to 0.72) and a similar risk of major bleeding (HR, 0.74; 95% CI, 0.49 to 1.11). Age did not modify the association for recurrent VTE (≥70 years: HR, 0.55; 95% CI, 0.36 to 0.83 versus <70 years: HR, 0.45; 95% CI, 0.26 to 0.78) or major bleeding (≥70 years: HR, 0.65; 95% CI, 0.39 to 1.07 versus <70 years: HR, 0.92; 95% CI, 0.44 to 1.89). Sex also did not modify the association for recurrent VTE (male: HR, 0.49; 95% CI, 0.31 to 0.79 versus female: HR, 0.56; 95% CI, 0.36 to 0.90) or major bleeding (male: HR, 0.70; 95% CI, 0.38 to 1.28 versus female: HR, 0.78; 95% CI, to 0.45 to 1.37).

Conclusions: DOACs were associated with a decreased risk of recurrent VTE and a similar risk of major bleeding compared to standard of care LMWH in patients with cancer associated VTE in routine clinical practice.

3798 | Risk of cardiovascular outcomes following addition of SGLT2 inhibitors versus sulfonylureas to baseline GLP-1RA therapy

Chintan Dave, Seoyoung Kim, Allison Goldfine, Robert Glynn, Angela Tong and Elisabetta Patorno

Brigham and Womens Hospital, Boston, MA

Background: Several glucagon-like peptide agonists (GLP-1RA) and sodium-glucose co-transporter 2 inhibitors (SGLT2i) have demonstrated cardiovascular benefit in type 2 diabetes in large randomized controlled trials. However, few trial participants were on both agents and it remains unknown whether the addition of SGLT2i to GLP-1RA therapy has further cardiovascular benefits, compared to the addition of agents without demonstrated reduction of cardiovascular events.

Objectives: To assess whether SGLT2i reduced cardiovascular events in patients with baseline GLP-1RA therapy.

Methods: Patients adding either SGLT2i or sulfonylureas to baseline GLP-1RA were identified within 3 US claims datasets (2013-2018) and were 1:1 propensity score matched (PSM) adjusting for >95 baseline covariates. The primary outcomes were 1) composite cardiovascular endpoint (CCE; comprised of myocardial infarction, stroke, and all-cause mortality) and 2) heart failure hospitalization. Adjusted hazard ratios (HR) and 95% confidence intervals (CI) were estimated in each dataset and pooled via fixed-effects meta-analysis.

Results: Among 12,584 propensity-score matched pairs (mean [SD] age 58.3 [10.9] year; male (48.2%)) across the 3 datasets, there were 102 CCE events [incidence rate per 1,000 person-years (IR) = 9.4] among SGLT2i initiators compared to 124 events [IR = 12.5] among sulfonylurea initiators corresponding to an adjusted pooled HR of 0.76 (95% CI: 0.59, 0.99); this decrease in CCE was driven by numerical decreases in the risk of MI (HR 0.71, 95% CI: 0.51, 1.001) and all-cause mortality (HR 0.60, 95% CI: 0.32, 1.14) but not stroke (HR 1.05, 95% CI: 0.62, 1.79). For the outcome of heart failure hospitalization, there were 141 events [IR = 13.0] among SGLT2i initiators versus 206 [IR = 20.8] events among sulfonylurea initiators corresponding to an adjusted pooled HR of 0.65 (95% CI: 0.52, 0.80).

Conclusions: In this large real-world cohort of diabetic patients on GLP-1RA, the addition of SGLT2i to GLP-1RA therapy conferred greater cardiovascular benefit compared to adding sulfonylureas. The magnitude of the cardiovascular risk reduction was comparable to the benefit seen in cardiovascular outcome trials of SGLT2i versus placebo where baseline GLP-1RA use was minimal.

3810 | Transporting treatment effects from clinical trials to clinical practice using a hybrid study approach: The case of adjuvant FOLFOX versus 5FU for colon cancer treatment

Jennifer L. Lund, Michael A. Webster-Clark, Alexander P. Keil, Daniel Westreich, Til Sturmer and Hanna K Sanoff

University of North Carolina at Chapel Hill, Chapel Hill, NC

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Treatment effects may differ between clinical trials and clinical practice, in part due to heterogeneous treatment effects combined with under-representation of certain patient subgroups in trials.
Objectives: We used a hybrid study approach combining clinical trial and real-world data to compare the effectiveness of adjuvant FOLFOX versus 5FU in reducing all-cause mortality among stage II-III colon cancer patients in community oncology practice.
Methods: We used the phase III Multicenter International Study of Oxaliplatin/5FU-LV in the Adjuvant Treatment of Colon Cancer (MOSAIC) combined with electronic health record data for patients who met trial eligibility criteria within US Oncology, a nationwide community oncology practice network, from 1/1/2008-5/31/2019. In the combined data, we used logistic regression to estimate the probability of trial enrollment as a function of age, sex, cancer substage, body mass index (BMI), and performance status. We estimated inverse odds of sampling weights and weighted MOSAIC participants to reflect four US Oncology populations of interest: 1) patients meeting trial eligibility criteria, 2) stage III patients (the approved indication), 3) stage III patients initiating FOLFOX, and 4) untreated patients (those least likely to benefit). Within the weighted trial populations, we estimated mortality hazard ratios (HRs) and bootstrapped 95% confidence intervals (CIs) comparing FOLFOX with 5FU.
Results: There were 2246 MOSAIC participants and 9335 US Oncology patients. In general, MOSAIC participants were younger, had more stage II cancer, lower BMI, and worse performance status compared with US Oncology patients. By six years, approximately 22% of MOSAIC participants died. The crude mortality HR estimate in MOSAIC comparing FOLFOX versus 5FU was 0.84 (0.71, 1.00). After weighting trial participants to reflect the US Oncology populations, HRs were attenuated to: 1.05 (080, 1.33) for all eligible US Oncology patients, 0.97 (0.73, 1.31) in the stage III subgroup, 0.93 (0.71, 1.25) in the stage III FOLFOX-treated subgroup, and 1.31 (0.84, 1.95) in the untreated subgroup.
Conclusions: Compared with trial results, we found that effectiveness of FOLFOX versus 5FU was attenuated in community oncology practice. The elevated HR estimates in the untreated population support oncologists' and patients' decisions to forgo adjuvant chemotherapy in those least likely to benefit.

3814 | Use of sodium-glucose co-transporter-2 inhibitors, changes in body mass index and risk of fracture: The clinical practice research datalink gold

Frank de Vries[1,2], Annemariek Driessen[1], Andrea Burden[1,3], Martijn Brouwers[1], Peter Vestergaard[4], Joop van den Bergh[1,5], Richard Eastell[6] and Judith van Dalem[1]
[1]*Maastricht University Medical Centre, Maastricht, Netherlands;* [2]*Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands;* [4]*ETH, Zurich, Switzerland;* [4]*Aalborg University Hospital and Aalborg University, Aalborg, Denmark;* [5]*VieCuri Medical Centre, Venlo, Netherlands;* [6]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*

Background: Type 2 diabetes mellitus is a metabolic disorder which has adverse effects on bone metabolism. Sodium-glucose co-transporter 2 inhibitors (SGLT2-Is) have been associated with reduced bone mineral density, increase in fracture risk and weight loss. Studies presented conflicting evidence regarding the association of SGLT2-Is on major osteoporotic fracture risk.
Objectives: The aim of this study was to investigate the association between SGLT2-Is, changes in Body Mass Index (BMI) and the risk of major osteoporotic fractures
Methods: Data from the Clinical Practice Research Datalink (CPRD) GOLD database (2013 - 2018) was used to conduct a retrospective population-based cohort study. The study population (n = 34,960) consisted of patients aged 18+ who had a first ever prescription of sulphonylureas (SU), dipeptidyl peptidase 4 inhibitors (DPP4-Is) or SGLT2-Is. Time-varying Cox proportional hazards models estimated the hazard ratio (HR) of major osteoporotic fracture risk of current SLGT-2I users versus current SU users. Analyses were stratified according to changes in BMI in current users of SGLT2-Is. Time-varying statistical adjustments were made for age, sex, life-style, comorbidities and drug use.
Results: Current use of SGLT2-Is was not associated with increased major osteoporotic fracture risk adjusted [adj.] HR: 0.89 (95% Confidence Interval [CI]; 0.61 - 1.31) when compared with SU users. Among current SGLT2-I users, loss of BMI ≥ than 1 kg/m^2 vs loss of BMI < than 0.5 kg/m^2 was not associated with major osteoporotic fracture, adj HR 0.81; 95% CI 0.63 - 1.04), whereas BMI gain ≥ than 1 kg/m^2 was associated with a 30% reduced risk of fracture, adj. HR 0.70; 95% CI (0.51 - 0.97).
Conclusions: Current use of SGLT2-Is was not associated with osteoporotic fracture risk when compared to current use of SUs. Among current SGLT2-I users, loss of BMI was not associated with risk of major osteoporotic fracture.

3828 | Impact of time in therapeutic range (TTR) on clinical outcomes in patients initiating treatment with warfarin

Kebede Beyene, Patricia Näslund, Amy Hai Yan Chan and Jeff Harrison
School of Pharmacy, The University of Auckland, Auckland, New Zealand

Background: The quality of warfarin therapy is markedly influenced by its time in therapeutic range(TTR), which is the duration of time in which the patient's International Normalized Ratio(INR) values are within a therapeutic range (INR: 2.0-3.0). Data on the quality of anticoagulation control and its effects on clinical outcomes in New Zealand(NZ) are lacking.
Objectives: To evaluate the quality of anticoagulation control and the association between TTR and clinical outcomes and all-cause mortality amongst incident warfarin users.
Methods: Using national healthcare databases, we performed a retrospective cohort study involving residents of Auckland (aged ≥18 year)

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

who newly started warfarin between January 2006 and December 2011. Only patients with more than 5 INR tests were included. TTR was calculated using the Rosendaal method. Patient were divided into 2 cohorts: those with good(TTR >60%) and poor(TTR ≤60%) anticoagulation control. Outcome measures were thromboembolic and bleeding events, and all-cause death. Patients were followed from warfarin initiation to the first occurrence of the target outcome, treatment discontinuation, death or end of follow-up(5 years). Time-varying Cox regression was used to evaluate whether TTR is independently associated with outcome measures, adjusting for sex, age, ethnicity, and deprivation index.

Results: A total of 4280 patients were included in the analysis. Mean age was 65±12 years, and 60.3% of the patients were male. The mean follow-up time was 2.76±1.7 years. Mean TTR was 55.3±17%, and 58.1% of patients had poor anticoagulation control(TTR ≤60%). A total of 435 thromboembolic and 758 bleeding events, and 657 deaths occurred during follow-up. Any thromboembolic(2.5 vs. 4.7) and bleeding events(4.5 vs 8.1), and all-cause death(3.4 vs. 7.5) incidence rates per 100-person years were lower in patients with good anticoagulation control compared with patients with poor control. Patients with good anticoagulation control had significantly lower risk for any thromboembolic events(HR: 0.546; 95% CI: 0.443-0.673), myocardial infraction(HR: 0.489; 95% CI: 0.355-0.673), any bleeding events(HR: 0.598; 95% CI: 0.509-0.703), major bleeding(HR: 0.636; 95% CI: 0.408-0.991), and all-cause mortality(HR: 0.433; 95% CI: 0.362-0.517) compared to patients with poor anticoagulation control.

Conclusions: The overall quality of anticoagulation control among Auckland residents was poor. Patients with poor anticoagulation control (TTR ≤60%) were at higher risk of adverse outcomes. These findings suggest a room for improvement in anticoagulation monitoring.

3892 | Effectiveness of dimethylfumarate on multiple sclerosis, a French cohort within SNDS nationwide claims database

Pauline Bosco-Levy[1,2], Patrick Blin[1], Séverine Lignot-Maleyran[1], Régis Lassalle[1], Abdelilah Abouelfath[1], Pauline Diez-Andreu[1], Marc Debouverie[3], Bruno Brochet[4], Francis Guillemin[5] and Nicholas Moore[1,6]

[1]Bordeaux PharmacoEpi, Univ. Bordeaux-INSERM CIC1401, Bordeaux, France; [2]Bordeaux Population Health Research Centre, INSERM UMR 1219, Bordeaux, France; [3]Department of Neurology, Nancy University-Hospital, EA 4360 APEMAC, Vandoeuvre-Lès Nancy, France; [4]CRC SEP, Service de Neurologie, CHU de Bordeaux, Bordeaux, France; [5]CHRU de Nancy, INSERM CIC 1433 Epidémiologie Clinique, Nancy, Université de Lorraine, EA 4360 APEMAC, Vandoeuvre-Lès Nancy, France; [6]CHU de Bordeaux, Bordeaux, France

Background: In the context of dimethylfumarate (Tecfidera®) registration renewal in 2020 in France, a cohort study was conducted using SNDS nationwide claims database.

Objectives: To assess the effectiveness of dimethylfumarate in the multiple sclerosis (MS) compared to other oral drugs (teriflunomide and fingolimod) and injectable immunomodulatory drugs (IID), in real life setting.

Methods: This cohort study included all patients identified in the SNDS with a first reimbursed dispensing of a MS drug (naive patients) from the 2015/07/01 to the 2017/12/31, with at least 4.5-year database history and followed until 31th December 2017. MS relapses were identified in the index drug exposure period using a validated algorithm (positive and negative predictive value: 95.2% and 100 %, respectively). We conducted multiple treatment-by-treatment comparisons of the mean annual number of relapses after 1:1 patients matching using a high-dimensional propensity scores (hdPS). A negative binomial regression model was used to estimate the relative risk (RR ± [95% CI]).

Results: During 1,5 years, 5812 naive patients were included: 1930 initiating teriflunomide (33.2%), 1800 an IID (31.0%), 1775 dimethylfumarate (30.6%) and 307 fingolimod (5.3%). The mean annual number of relapses was 0.14 in the 940 dimethylfumarate patients *versus* 0.17 in the 940 teriflunomide matched patients (RR = 0.79 [0.63 - 1.00], p=0.0457) and 0,14 in 1019 dimethylfumarate patients *versus* 0,18 in 1019 IID matched patients (RR =0,71 [0,56-0,90], p=0.0051). Too few fingolimod patients were identified to perform a treatment-by-treatment comparison.

Conclusions: This study showed a significantly lower risk of relapses with dimethylfumarate than teriflunomide and IID in real conditions of use among patients sharing the same characteristics.

3893 | Problematic alcohol use influences response to systemic therapies for psoriasis: Findings from a prospective multicentre cohort study

Ireny Y.K. Iskandar[1], Mark Lunt[2], Rachael J. Thorneloe[3], Lis Cordingley[4], Christopher E.M. Griffiths[5] and Darren M. Ashcroft[1]

[1]Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, University of Manchester, Manchester, United Kingdom; [2]Arthritis Research UK Epidemiology Unit, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom; [3]Department of Psychology, Sheffield Hallam University, Sheffield, United Kingdom; [4]Division of Musculoskeletal and Dermatological Sciences, University of Manchester, Manchester, United Kingdom; [5]NIHR Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom

Background: Psoriasis is a chronic inflammatory skin condition associated with considerable psychosocial difficulties; these may contribute to alcohol misuse. Conventional systemic and biologic therapies are used in the management of moderate to severe psoriasis; however, treatment effectiveness is lower in real-world clinical practice than in clinical trials. Factors that might influence response to treatment are varied, and generally, are poorly understood. The impact of alcohol misuse on response to treatment in psoriasis have not been investigated.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To investigate whether alcohol misuse influence response to treatment of moderate to severe psoriasis.

Methods: Prospective cohort study of patients with psoriasis aged at least 18 years old, attending 35 dermatology clinics across England and enrolled in the pharmacovigilance register the British Association of Dermatologists Biologics and Immunomodulators Register, and the iMAP (Investigating Medication Adherence in Psoriasis) study which collected biomedical and psychological data. Response to treatment was assessed using change in Psoriasis Area and Severity Index (PASI). The CAGE (cut-annoyed-guilty-eye) questionnaire was used to screen for alcohol misuse. A multivariable factional polynomial linear regression model, adjusting for other factors that could influence treatment response (demographic, clinical, and medication non-adherence), was implemented to analyse the data using STATAv15.0.

Results: The cohort included 266 patients (biologic treatment, n = 134; conventional systemic treatment, n = 132). In total, 16.6% of the study cohort were classified as non-adherent, with a higher proportion of patients using conventional systemic therapies classified as such (27.6%) compared to those using biologic therapies (5.9%). For the entire cohort, the median (interquartile range) PASI improved from 13 [10-18.3] at baseline to 3 [1-7.5] during follow-up. Obesity (regression co-efficient: 1.84; 95% CIs: 0.48-3.20), a higher CAGE score (1.40; 0.04-2.77), and receiving a conventional systemic rather than a biologic therapy (4.39; 2.84-5.95) were significantly associated with poor response to treatment; whereas a higher baseline PASI (-0.83; -0.92,-0.74) was associated with better response to treatment.

Conclusions: A poorer response to treatment associated with alcohol misuse calls for interventions to prevent, detect and manage alcohol consumption and misuse among people with psoriasis. These would minimise adverse health consequences and improve treatment response.

3956 | Comparative treatment effectiveness of oral fingolimod and injectable disease modifying agents in multiple sclerosis

Jagadeswara Rao Earla[1], George Joseph Hutton[2], J. Douglas Thornton[1], Hua Chen[1], Michael L. Johnson[1] and Rajender R. Aparasu[1]
[1]*University of Houston College of Pharmacy, Houston, TX;* [2]*Baylor College of Medicine, Houston, TX*

Background: Fingolimod was the first approved oral Disease Modifying Agent (DMA) to reduce relapses among individuals with Multiple Sclerosis (MS). Previous observational studies assessed the treatment effectiveness of DMAs only through relapse-based outcome measures and did not consider treatment switch as a measure of treatment effectiveness.

Objectives: To compare the treatment effectiveness of oral fingolimod and injectable DMAs using the composite treatment outcome measure - relapse/treatment switch - among patients with MS.

Methods: This retrospective longitudinal study included adults (≥18 years) with MS diagnosis (ICD-9-CM: 340) and a DMA prescription from the IBM MarketScan Commercial Claims and Encounters Database from 2010-2012. Patients were classified as oral fingolimod or injectable users based on their first DMA prescription (index DMA prescription). The relapse was defined as an inpatient hospitalization or an outpatient visit with a corticosteroid prescription within 30 days. The treatment switch was defined as switching of the index DMA to another DMA. The composite treatment outcome measure (relapse/treatment switch) was assessed during the one year followup period after the treatment initiation. Cox Proportional Hazards (PH) regression model adjusted for stabilized Inverse Probability Treatment Weights (IPTW) was used to evaluate composite treatment outcome measure -time to first relapse/treatment switch - between oral fingolimod and injectable DMA users. Patients who died or lost from follow-up due to the lack of insurance coverage were censored.

Results: The incident study cohort consisted of 1,997 MS patients who were initiated with oral (15.57%) or injectable (84.43%) DMAs during 2010-2011. The proportion of patients who had a composite outcome (relapse/treatment switch) in oral fingolimod and injectable DMA users was found to be 16.72% and 27.16%, respectively. The Cox PH regression model with stabilized IPTW revealed that fingolimod users were at lesser risk (Adjusted Hazards Ratio [AHR]-0.66, 95% CI: 0.50-0.86) of experiencing the composite outcome (relapse/treatment switch) than injectable DMA users.

Conclusions: Oral fingolimod was associated with a better composite treatment outcome compared to injectable DMAs. More comparative effectiveness research is needed based on the composite outcome measure to evaluate the newer oral DMAs introduced in the last decade.

3980 | Cohort selection in registry-based studies of direct oral anticoagulant users with atrial fibrillation: An inevitable trade-off between selection bias and misclassification

Maja Hellfritzsch[1,2], Erik L. Grove[2,3], Lotte Rasmussen[1], Simone B. Haastrup[2] and Anton Pottegård[1]
[1]*University of Southern Denmark, Odense, Denmark;* [2]*Aarhus University Hospital, Aarhus, Denmark;* [3]*Aarhus University, Aarhus, Denmark*

Background: Danish health registries are extensively used to study the safety and effectiveness of direct oral anticoagulants (DOAC) in atrial fibrillation (AF). Capturing the AF treatment indication is, however, challenging. Requirement of a registered hospital diagnosis of AF for cohort inclusion may introduce selection bias due to non-inclusion of many DOAC users with 'non-registered' AF. In contrast, not requiring this may introduce misclassification due to inclusion of DOAC users without AF.

Objectives: To assess the potential for selection bias and misclassification in studies on DOAC users with AF based on Danish registries.

Methods: We identified DOAC initiators between August 2011 and December 2018 (n=187,195). Using hospital diagnoses registered up until initiation, users were classified by assumed treatment indication in categories: AF (n=76,125), non-AF (*e.g.*, venous thromboembolism) (n=42,710), and no indication (n=68,360). The potential for selection bias was assessed by comparing one-year risks (cumulative incidence

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

proportions) of arterial thromboembolism, bleeding, and all-cause mortality between categories 'AF' and 'no indication'. To assess the potential for misclassification, we estimated the proportion of the 'no indication'-category that was diagnosed with AF or a non-AF indication in the year after initiation.

Results: The one-year risk of arterial thromboembolism was 4% and 5% in DOAC users with 'AF' and 'no indication', respectively (Hazards Ratio (HR) 1.27, 95% Confidence Interval (CI) 1.20-1.33). Mortality rates were also lower in the AF category (9%) than in the "no indication" category (11%) (HR 1.21, 95% CI 1.17-1.25). The one-year bleeding rates did not differ between groups (HR 0.95, 95% CI 0.91-0.99). In the 'no indication'-category, 32% and 4% received a diagnosis of AF and a non-AF treatment indication, respectively, in the year following DOAC initiation.

Conclusions: In 1/3 of Danish DOAC users, the indication for treatment cannot be identified when using hospital-based registries upon initiation. This study confirms that non-inclusion of these users likely introduces selection bias in effectiveness studies, whereas inclusion may lead to misclassification. To obtain the most balanced trade-off between these biases in cohort studies on DOAC users with AF, we suggest a main analysis including both the 'AF' and 'no indication'-category supplemented by a subgroup analysis including the 'AF'-category only.

4041 | Cardiovascular effectiveness of empagliflozin compared to DPP4 inhibitors and to GLP1 receptor agonists: Interim analysis from the empagliflozin comparative effectiveness and safety (EMPRISE) study

Elisabetta Patorno[1], Ajinkya Pawar[1], Jessica Franklin[1], Mehdi Najafzadeh[1], Deborah Wexler[2], Anouk Déruaz-Luyet[3], Kimberly Brodovicz[4], Lily Bessette[1] and Sebastian Schneeweiss[1]

[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany; [4]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT

Background: The EMPA-REG OUTCOME trial showed a reduction of 35% for heart failure hospitalization (HHF) and similar incidence of myocardial infarction and stroke in patients with type 2 diabetes (T2D) at high cardiovascular (CV) risk treated with empagliflozin (EMPA) vs. placebo, on top of standard of care. EMPRISE studies the comparative effectiveness, safety and healthcare utilization of EMPA in routine care of T2D patients across a broad spectrum of CV risk using data from Medicare and 2 U.S. commercial claims datasets from 08/2014 through 09/2019.

Objectives: To assess the association between EMPA and the risk of atherosclerotic cardiovascular (ASCV) events and HHF compared to DPP4 inhibitors (DPP4i) and to GLP1 receptor agonists (GLP-1RA) in an interim analysis from EMPRISE based on data from 08/2014 through 09/2017.

Methods: Within the 3 datasets (Medicare fee-for-service, Optum, and MarketScan), we identified 39,169 pairs of 1:1 propensity score (PS)-matched patients ≥18 years with T2D initiating EMPA or a DPP4i and 55,860 pairs initiating EMPA or a GLP-1RA. We assessed HHF, defined as either a discharge diagnosis of heart failure in the primary position (HHF-Specific) or in any position (HHF-Broad), and a combined ASCV outcome (comprised of myocardial infarction, stroke, hospitalization for unstable angina, or coronary revascularization). In each cohort, we estimated pooled hazard ratios (HR) and 95% confidence intervals (CI) adjusting for >140 baseline covariates, including several proxies of diabetes progression.

Results: After PS-matching, covariates were balanced with standardized differences <0.1, including lab test results available in a subset of the cohort and thus not included in the PS model. Over a mean follow-up of approximately six months, EMPA was associated with a decreased risk of HHF [HHF-Specific: 0.42 (0.31-0.58); HHF-Broad: 0.59 (0.51-0.69)] and a similar risk of the ASCV outcome [HR (95% CI) = 0.88 (0.74-1.03)] compared with DPP4i. Results for EMPA vs GLP-1RA were similar: HHF-Specific [0.63 (0.49-0.80)], HHF-Broad [0.83 (0.74-0.93)] and ASCV outcome [0.99 (0.87-1.13)]. Results for the individual components of the ASCV outcome were consistent.

Conclusions: An interim analysis from EMPRISE showed that compared with DPP4i or GLP-1RA, EMPA was associated with a decreased risk of HHF in routine clinical care and a similar risk of ASCV events. These results are consistent with trial data and reinforce the notion of the major role that HHF risk may play in deciding when to prescribe EMPA.

4063 | Statins and risk of diverticular disease: nested case-control study in Denmark

Nils Skajaa[1], Frederikke Schønfeldt Troelsen[1], Ola Ekholm[2], Lars Pedersen[1], Rune Erichsen[1] and Henrik Toft Sørensen[1]

[1]Aarhus University, Aarhus N, Denmark; [2]National Institute of Public Health, Copenhagen, Denmark

Background: Statins may affect the occurrence of diseases not clearly related to cholesterol levels through direct and indirect pathways. Whether statins affect the development of diverticular disease, a highly prevalent condition, remains poorly understood with previous studies obtaining divergent results.

Objectives: To examine the association between statin use and diverticular disease.

Methods: We conducted a nested case-control study in Denmark during 2010-2018. The source population consisted of respondents (>18 years) of the 2010 or the 2013 Danish National Health Survey. We linked this population to nationwide health and administrative registries and identified 8,809 cases of hospital-diagnosed diverticular disease and risk-set sampled population controls without diverticular disease, matched 1:10 on age, sex, and year of survey. Using complete prescription (since 2005) and hospital records (since 1977) among

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cases and controls, we applied conditional logistic regression to compute crude and adjusted odds ratios (ORs) associating statin use with diverticular disease. In adjusted analyses, we controlled for indications for statin initiation, including medication use other than statins, and lifestyle-related factors associated with diverticular disease, including diet, smoking, alcohol consumption, and physical activity.

Results: The adjusted OR for diverticular disease associated with ever use (≥1 statin prescription filling) was 1.18 (95% CI: 1.11-1.27) compared with no-use. This association was robust for both lipophilic and hydrophilic statins and across strata of age and sex. The adjusted OR was somewhat higher for cases of diverticulitis requiring surgery (1.36 [95% CI: 1.06-1.76]) than for those not requiring surgery (1.16 [95% CI: 1.07-1.25]). In analyses taking into account both the duration and intensity of statin use, associations resembled that of the main analyses. For example, among short-term users (<5 years), the OR was 1.15 (95% CI: 1.00 - 1.33) for low intensity users and 1.15 (95% CI: 1.02-1.29) for high intensity users. Similarly, among long-term users (≥5 years), the respective ORs were 1.25 (95% CI: 1.12-1.39) and 1.10 (95% CI: 0.97-1.24).

Conclusions: Statin use was associated with an increased risk of diverticular disease, particularly cases of diverticulitis requiring surgery. The increased risk persisted among the long-term and most intense users, but may be explained by residual confounding.

4065 | Statins and risk of amyotrophic lateral sclerosis: Danish population-based cohort study

Nils Skajaa[1], Istvan Bakos[1], Erzsébeth Horváth-Puhó[1], Victor W. Henderson[1,2], Timothy Lash[1,3] and Henrik Toft Sørensen[1]

[1]Aarhus University, Aarhus N, Denmark; [2]Stanford University, Stanford, CA; [3]Rollins School of Public Health, Emory University, Atlanta, GA

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease. The evidence of an association between statins, common cholesterol-lowering drugs with pleotropic properties, and ALS is scattered and inconclusive.

Objectives: To examine the effect of statin initiation on the risk of ALS.

Methods: We performed a population-based cohort study involving 767,694 statin initiators aged ≥ 18 years and 1,535,388 sex-, age-, and calendar year-matched (1:2) general population comparators identified 1 January 2005 to 31 December 2016 from Danish, nationwide registries. We computed cumulative risks and hazard ratios (HRs) of a first-time ALS diagnosis controlling for medically diagnosed comorbidities, including comedications, in one analysis and propensity-score in another.

Results: The 12-year cumulative risk of ALS among statin initiators was 0.11% (95% confidence interval [CI]: 0.10-0.12), yielding a comorbidity-adjusted HR of 1.26 (95% CI: 1.11-1.42). The risk was higher among women (HR: 1.38 [95% CI: 1.16-1.64]) than men (HR: 1.15 [95% CI: 0.97-1.37]) and during the first year since statin initiation (HR: 1.84 [95% CI: 1.39-2.42]). However, associations decreased to unity during 5-12 years since initiation (HR: 0.99 [95% CI: 0.79-1.23]). Associations were similar for lipophilic and hydrophilic statins, when a stricter definition of ALS was used, and when HRs were adjusted for the propensity-score.

Conclusions: We found evidence of an association between statin initiation and ALS. The association was strongest in the first year since statin initiation, suggesting a possible acute neurotoxic effect. However, the lack of a long-term effect may indicate bias which warrants further investigation.

4071 | The risk of overdose associated with concomitant use of antipsychotic agents and prescription opioids

Alejandro Szmulewicz[1], Brian Bateman[2], Raisa Levin[3] and Krista Huybrechts[1]

[1]Harvard School of Public Health, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Background: As chronic pain and mental conditions commonly co-occur, prescription opioids and antipsychotics (AP) are frequently used concomitantly. Concerns exist that concomitant use of these agents may increase the risk of unintended overdose.

Objectives: To determine the rate of overdose among patients using opioids and AP agents as compared to those using opioids alone, and to establish if sedating AP yield a higher risk than non-sedating AP.

Methods: We conducted a cohort study using IBM Health MarketScan research databases 2004-2017. Patient episodes with concomitant exposure to any AP agent and prescription opioids ('exposed') were 1:1 matched to patient episodes with exposure to prescription opioids alone ('reference') based on: type of opioid, morphine equivalents, calendar year, and hospitalization within the last 30 days of the qualifying prescription. Patients with cancer or palliative care were excluded. For the secondary analyses, episodes of opioids plus AP use were divided into 'sedating' (e.g., quetiapine) and 'non-sedating' (e.g., aripiprazole). The same matching factors plus chlorpromazine equivalents were applied. The primary outcome was opioid and/or psychotropic-related overdose within 30 days of index date (i.e., date of the AP prescription for the exposed and matched date for the reference), using an intention-to-treat approach. Hazard Ratios (HR) and 95% CI were estimated from Cox proportional hazard regression models with fine stratification on the propensity score (including 65 variables) to control for confounding.

Results: The cohort comprised 85,973 exposed and an equal number of matched reference episodes. Mean age was 49 years and 40% were male. Patients with concomitant AP use had higher concomitant psychotropics, number of clinical diagnoses, psychiatric visits and comorbidities at baseline. There were 143 overdoses among the exposed (20.6 per 1,000 person-years) versus 15 among the referent (2.2 per 1,000 person-years) within 30 days, for an unadjusted HR of 9.26 (95% CI: 5.44-15.76). With fine stratification on the PS, the HR attenuated to 1.31 (1.02-1.69). In secondary analyses, we found no

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

difference in the risk of overdose comparing sedating to non-sedating AP (HR: 1.00, 95% CI: 0.61-1.63).

Conclusions: Among patients receiving prescription opioids, concomitant AP use was associated with an increased risk of overdose. No differences between AP agents was found based on their sedating potential. Caution is required when prescribing these agents to patients on opioid therapy and interventions to improve rational prescribing are needed.

4091 | Outcomes in patients receiving nintedanib or pirfenidone for idiopathic pulmonary fibrosis

Vincent Cottin[1], Paolo Spagnolo[2], Philippe Bonniaud[3], Maeva Nolin[4], Faustine Dalon[4], Jenny Chia[5], Klaus Kirchgässler[6], Tripthi Kamath[5], Eric Van Ganse[4] and Manon Belhassen[4]

[1]National Reference Coordinating Center for Rare Pulmonary Diseases, Louis Pradel Hospital, Hospices Civils de Lyon, Université de Lyon, Université Claude Bernard Lyon 1, UMR754, IVPC, Member of ERN-LUNG, Lyon, France; [2]Respiratory Disease Unit, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padova, Padova, Italy; [3]Service de Pneumologie et Soins Intensifs Respiratoires, Centre de Référence Constitutif des Maladies Pulmonaires Rares de l'Adulte, Centre Hospitalo-Universitaire de Bourgogne, Faculté de Médecine et Pharmacie, Université de Bourgogne-Franche Comté, Dijon, France; [4]PELyon, Lyon, France; [5]Genentech, Inc., South San Francisco, CA; [6]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: Idiopathic pulmonary fibrosis (IPF) is a chronic, progressive, irreversible, and ultimately fatal disease of unknown aetiology. Currently, pirfenidone and nintedanib are the only two approved drugs for IPF.

Objectives: The aim of this study was to assess all-cause mortality and acute respiratory-related hospitalizations in IPF patients either untreated or receiving pirfenidone or nintedanib.

Methods: We conducted a cohort study using French National Health System claims data on individuals aged ≥50 years diagnosed with IPF between January 2015 and December 2016. Cumulative incidence rates were estimated for untreated and patients newly treated with pirfenidone or nintedanib. All-cause mortality, acute respiratory-related hospitalizations, and treatment discontinuations were compared among newly pirfenidone- and nintedanib-treated patients, using a Cox proportional hazards model adjusted for confounders.

Results: Among the 7,194 identified IPF patients (63% of males, mean age of 74.9 years old), 521 (7,2%) were not newly treated patients and were therefore not included in the study; 5,360 (74.5%) remained untreated, while 804 (11.2%) initiated pirfenidone and 509 (7.1%) initiated nintedanib during the study period. The cumulative all-cause mortality at three years was 50.23% (95% CI=[48.34%-52.09%]) in untreated patients, 25.5% (95% CI=[19.6%-31.7%]) in pirfenidone-treated patients, and 31.1% (95% CI=[21.2%-41.6%] in nintedanib-treated patients. After adjustment for age at index date, gender, year of index date, time in months between IPF diagnosis and index date, and proxies of severity identified during the 12 months before index date, nintedanib was associated with higher risks of all-cause death and acute respiratory-related hospitalization than pirfenidone over the exposure period (HR=1.80, 95% CI=[1.25-2.60], and HR=1.32, 95% CI=[1.01-1.73], respectively). However, nintedanib was also associated with a lower risk of treatment discontinuation at 12 months than pirfenidone (HR=0.72, 95% CI=[0.60-0.86]).

Conclusions: Compared to nintedanib, pirfenidone was associated with lower risks of death and acute respiratory-related hospitalizations but with a higher risk of treatment discontinuation at 12 months. Although data interpretation is limited by the observational design of the study, these findings suggest possible differences in effectiveness between available drugs for IPF.

Funding: F. Hoffmann-La Roche, Ltd/Genentech, Inc.

4100 | Comparative effectiveness of ovulation induction medications: Evidence from a large healthcare database in the United States

Jennifer J. Yland[1,2], Yu-Han Chiu[1], Sean McGrath[1] and Sonia Hernández-Díaz[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA; [2]Boston University School of Public Health, Boston, MA

Background: Clomiphene citrate (CC) and letrozole are used to induce ovulation in women with infertility. Several randomized trials have observed improved ovulation and pregnancy rates among women treated with letrozole compared with CC. However, little is known about the comparative neonatal outcomes associated with these medications.

Objectives: To evaluate pregnancy outcomes among women treated with CC compared to letrozole.

Methods: This study was conducted within the IBM MarketScan Commercial Claims and Encounters Database for 2011-2015. We identified dispensations of CC and letrozole among women aged 18-50 and excluded women with contraindications, breast cancer, or use of assisted reproductive technology. We followed women from first cycle, through up to one year of treatment, to end of pregnancy, treatment failure, or end of enrollment. We identified pregnancies with an estimated last menstrual period within 60 days of the last dispensation of CC or letrozole and evaluated pregnancy outcomes. We then identified pregnancies linked to a liveborn infant and evaluated preterm birth (PTB), small for gestational age (SGA), major congenital malformations overall, hypospadias, and cryptorchidism. We estimated odds ratios (ORs) and 95% confidence intervals (CIs) and adjusted for potential confounders. We also stratified analyses by intrauterine insemination (IUI) and polycystic ovarian syndrome (PCOS).

Results: 35,288 and 15,661 women initiated ovarian stimulation cycles with CC and letrozole, respectively. We identified clinical pregnancies among 38% and 34% of women who received CC and letrozole, respectively over cumulative treatment cycles, among which

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

a livebirth was attained in 88% for each group. After infant-linkage, we analyzed data from 7,899 livebirths conceived with CC and 3,800 with letrozole. IUI was used among 21% and 24% of pregnancies in the CC and the letrozole groups, respectively. The proportion of pregnancies with multifetal gestation was about 10% in both groups. There were few differences in neonatal outcomes between infants conceived by the two treatment groups. The ORs (95% CIs) for PTB, SGA, and malformations overall were 1.10 (0.98, 1.23), 0.86 (0.72, 1.02), and 1.09 (0.88, 1.35), respectively, comparing newborns conceived with letrozole with those conceived with CC. Estimates were unstable for specific malformations. Results were similar within non-IUI and IUI pregnancies and within women with and without PCOS.

Conclusions: Conditioning on livebirth, neonatal outcomes were generally similar in pregnancies conceived with CC versus letrozole.

4112 | Risk of cardiovascular events and serious hypoglycemia comparing patients with type 2 diabetes initiating a GLP1RA or basal insulin: A propensity score matched cohort study

Jing Luo[1], Deborah Wexler[2], Dae Kim[3], Seoyoung Kim[4] and Elisabetta Patorno[4]

[1]University of Pittsburgh, Pittsburgh, PA; [2]Massachusetts General Hospital, Boston, PA; [3]Hebrew Rehabilitation Center, Boston, MA; [4]Brigham and Women's Hospital, Boston, MA

Background: Head-to-head open label trials comparing selected GLP-1RA(s) versus basal insulin(s) have not evaluated cardiovascular outcomes.

Objectives: To determine the risk of serious cardiovascular events and serious hypoglycemia comparing patients with type 2 diabetes newly initiating a GLP-1RA or basal insulin.

Methods: Using 2 large U.S. commercial claims databases (Optum and Truven MarketScan) from 01/2012 to 12/2017, we assessed the risk of a composite cardiovascular outcome (MI, stroke) and serious hypoglycemia defined by validated claims-based algorithms comparing 26,308 patients with type 2 diabetes with prior or concurrent metformin therapy newly initiating an injectable GLP-1RA or basal insulin. We estimated pooled incidence rates, meta-analyzed hazard ratios and 95% CI adjusting for >140 baseline clinical characteristics, including HbA1c.

Results: Baseline clinical characteristics were well-balanced in the two groups after 1:1 propensity score matching. In an as-treated analysis, the median follow-up was 148 days. The mean age was 57.9 (SD 4.4-4.9) with 48% female. Sixteen percent of patients had pre-existing ischemic heart disease at baseline. The mean(SD) baseline HbA1c was 8.64 (0.83). All patients had received prior or concurrent metformin therapy. Compared to basal insulin, initiating a GLP-1RA was associated with a lower risk of MI or stroke [HR 0.68; 95% CI 0.51-0.90] and lower risk of serious hypoglycemia [HR 0.38; 95% CI 0.25-0.57].

Conclusions: These results support recent clinical treatment guidelines that recommend starting a GLP-1RA before basal insulin for patients with type 2 diabetes with inadequate glycemic control despite metformin.

4129 | SGLT2 inhibitors and the risk of major adverse cardiovascular events: A multi-database study using a prevalent new-user design

Kristian B. Filion[1], Lisa M. Lix[2], Oriana H.Y. Yu[3], Sophie Dell'Aniello[3], Antonios Douros[1], Baiju R. Shah[4], Audray St-Jean[3], Anat Fisher[5], Eric Tremblay[6], Shawn C. Bugden[7], Silvia Alessi-Severini[2], Paul E. Ronksley[8], Nianping Hu[9], Colin R. Dormuth[5], Pierre Ernst[1], Samy Suissa[1] and the CNODES Investigators[10]

[1]McGill University, Montreal, QC, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Lady Davis Institute, Montreal, QC, Canada; [4]University of Toronto, Toronto, ON, Canada; [5]University of British Columbia, Vancouver, BC, Canada; [6]Institut National d'Excellence en Santé et en Services Sociaux, Quebec City, QC, Canada; [7]Memorial University of Newfoundland, St John's, NL, Canada; [8]University of Calgary, Calgary, AB, Canada; [9]The Health Quality Council, Saskatoon, SK, Canada; [10]Canadian Network for Observational Drug Effect Studies (CNODES) Investigators, Montreal, QC, Canada

Background: Most randomized controlled trials suggest that sodium-glucose cotransporter 2 (SGLT2) inhibitors reduce the risk of major adverse cardiovascular events (MACE) among patients with type 2 diabetes. However, their effectiveness in a real-world setting remains uncertain.

Objectives: We compared SGLT2 inhibitors versus dipeptidyl peptidase-4 (DPP-4) inhibitors on the incidence of MACE (a composite endpoint of myocardial infarction, ischemic stroke, and cardiovascular death), the individual components of MACE, heart failure, and all-cause mortality among patients with type 2 diabetes.

Methods: As part of the Canadian Network for Observational Drug Effect Studies (CNODES), we conducted a multi-database retrospective cohort study using healthcare databases from seven Canadian provinces and the United Kingdom over the period 2013-2018. Using a prevalent new-user design, we matched each new user of a SGLT2 inhibitor to a DPP-4 inhibitor user on time-conditional propensity scores. Our primary endpoint was MACE. We used Cox proportional hazards models to estimate site-specific adjusted hazards ratios (HRs) and 95% confidence intervals (CIs), comparing exposure to SGLT2 inhibitors with DPP-4 inhibitors using an as-treated approach. Site-specific results were pooled using random-effects meta-analysis.

Results: A total of 209,867 new users of SGLT2 inhibitors was matched to 209,867 users of DPP-4 inhibitors. During a mean follow-up of 0.9 years (standard deviation: 0.76), MACE occurred in 2,146 SGLT2 inhibitor users (incidence rate: 11.4 per 1,000 person-years) and 3,001 DPP-4 inhibitor users (incidence rate: 16.5 per 1,000 person-years). Compared with DPP-4 inhibitors, SGLT2 inhibitors were associated with decreased risks of MACE (HR: 0.76, 95% CI: 0.69-0.84), myocardial infarction (HR: 0.82, 95% CI: 0.70-0.96), cardiovascular death (HR: 0.60, 95% CI: 0.54-0.67), heart failure (HR:

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

0.43, 95% CI: 0.37-0.51), and all-cause mortality (HR: 0.60, 95% CI: 0.54-0.67). SGLT2 inhibitors had more modest benefits for ischemic stroke (HR: 0.85, 95% CI: 0.72-1.01). We observed similar benefits with respect to MACE with canagliflozin (HR: 0.79, 95% CI: 0.66-0.94), dapagliflozin (HR: 0.73, 95% CI: 0.63-0.85), and empagliflozin (HR: 0.77, 95% CI: 0.68-0.87). Similar results were observed for MACE across patient subgroups defined by age, sex, prior use of insulin, and history of cardiovascular disease.

Conclusions: In this large observational study, SGLT2 inhibitors were associated with a decreased risk of serious cardiovascular events compared with DPP-4 inhibitors.

4156 | The impact of opioids on adverse events among older breast cancer survivors

Aaron N. Winn[1], Devon Check[2], Nicole M. Fergestrom[1], Joan M. Neuner[1] and Andrew W. Roberts[3]
[1]*Medical College of Wisconsin, Milwaukee, WI;* [2]*Duke University, Durham, NC;* [3]*University of Kansas Medical Center, Kansas City, KS*

Background: Older adults and cancer survivors are underrepresented in prior research. As prevention of unnecessary opioid use gains importance in clinical practice, it is needed to fully capture the risks of opioid related adverse events among patients with cancer pain.

Objectives: The objective of this study was to determine the association between opioid use after cancer diagnosis and comprehensive opioid-related adverse events among older adult breast cancer survivors.

Methods: We conducted a retrospective cohort study using Surveillance, Epidemiology, and End Results tumor registry data linked with Medicare claims for women who received a new diagnosis of stage 0-III breast cancer at the age of 66 to 90 between 2008-2015. The study observation period was the year following a patient's end of active cancer treatment. The primary independent variable was a repeated daily measure of opioid exposure based on Part D prescription claims. The primary outcomes were daily indicators of all-cause hospitalization, substance use event and a composite of other opioid-related adverse events (infections, gastrointestinal events, falls/fractures, cardiovascular events). We estimated the association of current opioid use and the immediate risk of an outcome the following day using modified Poisson generalized estimating equation models. We adjusted for patient demographics, cancer characteristics and cancer treatments received. We conducted sensitivity analyses that examined a dose response relationship by measuring opioid exposure as greater than or less than 50 morphine milligram equivalents (MME).

Results: We found that opioid exposure more than doubled the immediate risk of all-cause hospitalization (aRR= 2.77; 95%CI=2.57, 2.99; p<0.001) and having a composite adverse event (aRR= 2.50; 95% CI=2.18, 2.87; p<0.001) and dramatically increases the immediate risk of a substance use event (aRR= 14.26; 95%CI=7.11, 28.59; p<0.001). In sensitivity analyses, we find consistent increased risk with increased dosages of opioids. For example, opioid exposure≥50 MME almost quadruples the risk of being hospitalized (aRR= 3.94; 95% CI=3.45, 4.51; p<0.001) whereas opioid exposure<50 MME doubles the risk of being hospitalized (aRR= 2.49; 95%CI=2.28, 2.71; p<0.001) compared to no opioid exposure.

Conclusions: Older adult breast cancer survivors with continued prescription opioid use in the year after completing cancer treatment experienced an immediate increased risk of all-cause hospitalization, substance use events, and opioid-related adverse effects. Clinicians should consider the comprehensive risks of opioids in managing cancer pain.

4184 | Interventions to improve medication adherence in patients with inflammatory bowel disease: A systematic review

Shrey Gohil, Zahra Majd, Jared C. Sheneman and Susan Abughosh
University of Houston College of Pharmacy, Houston, TX

Background: Medication nonadherence in patients with inflammatory bowel disease (IBD) is associated with disease aggravation, unsatisfactory clinical outcomes, high healthcare consumption, and increased costs.

Objectives: The aim of this study is to summarize existing literature examining interventions to enhance medication adherence and their impact on patients with IBD.

Methods: This review was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement. PubMed and Embase were searched for studies from June 2014 to June 2019 using the following terms: "inflammatory bowel disease" or "IBD" or "ulcerative colitis" or "Crohn's disease," "adherence" or "compliance" or "persistence," "intervention," and "medication" or "treatment". Only the studies published in English were included. Randomized controlled trials, observational studies, and mixed methods design studies were included. Studies were excluded if they were reviews, case reports, case series, conference abstracts, or study protocols. At least two investigators independently determined the eligibility of studies, extracted data and summarized the results.

Results: Our systematic literature search identified four hundred eighty-eight published articles. Sixteen studies with a total of 6311 patients were included in this review based on inclusion and exclusion criteria. Out of sixteen different interventions, eight were classified as educational, five as multicomponent, two as behavioral and one as cognitive-behavioral. Adherence was measured using patient self-report, administrative/pharmacy claims data, and electronic monitoring devices/pill dispensing systems. Eleven out of sixteen interventions showed a statistically significant improvement in medication adherence including five educational, four multicomponent, one behavioral and one cognitive-behavioral intervention.

Conclusions: Literature assessing different intervention strategies to improve medication adherence among patients with IBD is sparse. Majorly, educational and multicomponent interventions are evaluated. Multicomponent interventions demonstrated the greatest impact on IBD patients in promoting medication adherence. Future research should focus on a multidisciplinary approach to design multicomponent interventions that synergize impact and maximize success.

4193 | Effect duration of intramuscular benzathine penicillin for preventing recurrence of cellulitis

Nai-Yu Chen[1], Kuan-Sheng Wu[2], Chien-Chou Su[1] and Edward Chia-Cheng Lai[1]

[1]*Institute of Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan;* [2]*Section of Infectious Diseases, Department of Internal Medicine, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*

Background: Intramuscular benzathine penicillin (IM penicillin) every 3 to 4 week is often used to prevent recurrence of cellulitis. However, limited information on its effect duration was available, lingering the question that the optimal frequency of IM penicillin remained unclear.

Objectives: To evaluate the effect duration of IM penicillin for prevention of cellulitis recurrence.

Methods: We analyzed the data of 2 million individuals randomly sampled from Taiwan's National Health Insurance Database from 2004-2013. We included patients newly diagnosed with cellulitis receiving IM penicillin for prevention of recurrent cellulitis. We excluded patients receiving any kind of antibiotics within 14 days of wash-out period before IM penicillin. Included patients were followed up for 27 days from IM penicillin. We censored patients at the time of cellulitis recurrence or receive of the next IM penicillin. We calculated the incidence rate of recurrent cellulitis for the time intervals of day 0-6, 7-13, 14-20 and 21-27 respectively. We used piecewise Cox regression to evaluate the risk of recurrent cellulitis for each time interval, compared to the first time interval (ie, day 0-6).

Results: We included a total of 314 patients received IM penicillin. The mean age was 67.26 (SD 17.02) years old and 38.85% of them were female. The overall incidence rate of recurrent cellulitis within 27 days was 17.14 per 100 person-day. The incidence rate of recurrent cellulitis were 2.87, 6.56, 3.51, and 3.64 per 100 person-day for the intervals of day 0-6, 7-13, 14-20 and 21-27, respectively. Compared to the day 0-6, we found the hazard ratio of recurrent cellulitis were 2.29 (95% CIs, 1.47-3.39) for day 7-13,1.22 (95% CIs, 0.76-1.94) and 1.27 (95% CIs, 0.77-2.05) for day 21-27.

Conclusions: The findings indicated the risk of recurrent cellulitis was higher in day 7-13, suggesting the effect duration of IM penicillin may limit to only one week. The study warrants re-consideration on optimal frequency of using IM penicillin for preventing recurrent cellulitis.

4196 | Clinical outcome and medical cost of brand-name and generic antihypertensive drugs: A population-based study in Yinzhou, China

Tao Huang[1], Haishaerjiang Wushouer[2,3,4], Mingchun Yang[1], Luwen Shi[1,4] and Xiaodong Guan[1,4]

[1]*Department of Pharmacy Administration and Clinical Pharmacy, School of Pharmaceutical Sciences, Peking University, Beijing, China;* [2]*Center for Strategic Studies, Chinese Academy of Engineering, Beijing, China;* [3]*School of Medicine, Tsinghua University, Beijing, China;* [4]*International Research Center for Medicinal Administration, Peking University, Beijing, China*

Background: The substitution of generic drugs can effectively alleviate the rapid growth of drug cost, however, the clinical effectiveness and medical cost of Chinese brand and generic drugs were never studied.

Objectives: To compare the effectiveness of antihypertensive drugs and hypertension related medical cost between brand-name and generic initiators in Yinzhou, Zhejiang, China.

Methods: We conducted a population-based retrospective cohort study using healthcare database from The Chinese Electronic health Records Research in Yinzhou (CHERRY), from 1st July 2011 to 31st December 2018. Hypertension patients initiating with brand-name products were compared with patients initiating with generics, for irbesartan, valsartan, losartan, metoprolol, amlodipine, nifedipine and felodipine. We used 1:1 propensity score matching to pair the two groups based on sociodemographic, clinical, and health service utilization variables. Cox proportional regression was adopted to compare the rate of hospitalization with myocardial infarction or ischemic stroke between matched brand-name and generic initiators. Multivariable linear regression was used to compare the daily hypertension related medical cost within the follow-up between the two groups.

Results: Among 7 drugs, 17102 matched pairs of patients were included in the study. A majority (6 out of 7) of the clinical endpoint estimates showed similar outcomes between brand-name products and generics (irbesartan HR[95%CI]: 0.69[0.30-1.57], valsartan HR[95%CI]: 0.90[0.55-1.47], losartan HR[95%CI]: 0.89[0.59-1.35], metoprolol HR [95%CI]: 0.87[0.60-1.26], nifedipine HR[95%CI]: 0.91[0.56-1.47] and felodipine HR[95%CI]: 0.73[0.36-1.48], respectively). While for amlodipine, lower risk of hospitalization with myocardial infarction or ischemic stroke was observed in brand-name products (HR[95%CI]: 0.43[0.23-0.78]). For all 7 drugs, increasing daily medical cost of brand-name initiators versus generic initiators was observed (irbesartan β[95% CI]: 13.4[2.8-24.0], valsartan β[95%CI]: 7.5[5.0-10.1], losartan β[95% CI]: 15.8[11.0-20.6], metoprolol β[95%CI]: 29.3[11.1-47.6], amlodipine β[95%CI]: 24.0[7.1-41.0], nifedipine β[95%CI]: 29.4[17.6-41.3] and felodipine β[95%CI]: 5.54[3.43-7.67], respectively).

Conclusions: We observed comparable clinical outcomes and less medical cost associated with the use of antihypertensive generics versus brand-name products, which could help increase patient and provider confidence in the ability of generic medicines to manage hypertension diseases.

4197 | Real-world effectiveness of oral disease-modifying therapies for multiple sclerosis

Thanh Phuong Pham Nguyen, Dylan Thibault and Allison Willis

University of Pennsylvania, Philadelphia, PA

Background: Oral disease-modifying therapies (DMTs), namely dimethyl fumarate (DMF), fingolimod and teriflunomide, have become standard

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

treatments for multiple sclerosis (MS). Clinical trials demonstrated a reduction in annual relapse rate, but real-world data is lacking.

Objectives: To evaluate the real-world effectiveness of oral DMTs.

Methods: We used a multi-insurance database, Optum™ Clinformatics™, to conduct a retrospective cohort study of adult non-pregnant users of U.S.-approved oral DMTs for MS from 09/2010 until 9/2015. The study outcome was hospitalization with MS documented as the primary reason for hospitalization, an approximation of the clinical trial endpoint of hospitalization for MS relapse. Study subjects were required to have a minimum of two years of claims data after the first oral DMT prescription fill. Hospitalization for MS was estimated by the number of relapses per 1,000 patient-year1 using Poisson regression models. Time to first relapse was also examined using Cox proportional hazard models, which included individual level covariables for age, sex, race/ethnicity (white vs. minority), education level (high school or less vs. college or beyond), household income, previous treatment with injectable DMT, switching of oral DMT during observation period, and time since MS diagnosis.

Results: We identified 3,297 persons meeting all inclusion criteria. The unadjusted incidence rate ratios (IRRs) of MS hospitalizations were low for all DMTs, with a rate of 36 per 1,000 patient-years for DMF, 43 per 1,000 patient-years for teriflunomide, and 45 per 1,000 patient-years for fingolimod. Cox models found an increased risk of relapse associated with switching DMT (aHR 2.17, 95%CI 1.68-2.79), and minority race/ethnicity (aHR 1.39, 95%CI 1.28-1.51). As compared to the lowest income category, mid- and highest-level incomes had a lower risk of MS hospitalization, (aHRs 0.64, 95%CI 0.43-0.97 and 0.46, 95%CI 0.33-0.61, respectively), but the unknown/missing income category had the highest risk of MS hospitalization (aHR 1.24, 95%CI 1.03-1.52). There were no statistically significant differences in the risk of relapse associated with sex or education category, nor for fingolimod or DMF compared to teriflunomide.

Conclusions: Oral DMT performance in the real world is similar to clinical trials. Additionally, the three oral DMTs studied are comparably effective for the outcome of MS hospitalization. These data allow oral DMT therapy decision making to focus on other important factors such as safety potential, prior treatment response, disease progression, patient preference, therapy access and cost.

4212 | Comparing the effect of combining exercise with rosuvastatin versus atorvastatin on lipid profile and functional capacity: A retrospective cohort study

Sherif Eltonsy[1], Monique Dufour Doiron[2], Patrice Simard[3], Caroline Jose[2], Martin Senecal[4], Danielle Bouchard[4], Remi LeBlanc[5] and Mathieu Belanger[2]

[1]University of Manitoba, Winnipeg, MB, Canada; [2]Universite de Moncton, Moncton, MB, Canada; [3]Universite de Montreal, Montreal, MB, Canada; [4]University of New Brunswick, Fredericton, MB, Canada; [5]Universite de Sherbrooke, Winnipeg, QC, Canada

Background: Rosuvastatin and atorvastatin are the most commonly used types of statins, especially among older adults. Statins and exercise are recommended for managing hypercholesterolemia. However, statin types may vary in their interaction with exercise. Statin types vary in their lipophilicity and pharmacological properties, which affect their tissue penetration, including skeletal muscle tissues

Objectives: we present a real-world comparison of rosuvastatin versus atorvastatin combination with exercise to assess interactions between type of statin used and exercise on lipid profile and functional capacity

Methods: A retrospective cohort study using data from participants in a 12 week cardiovascular rehabilitation program between 2014-2016. Statins use was determined through prescriptions and average exercise minutes/week were computed from exercise logs. The cohort included 282 patients from 106 atorvastatin and 176 rosuvastatin users. The primary outcomes were changes in total cholesterol, low- and high-density lipoproteins (LDL & HDL), triglycerides and functional capacity (6-minute walk test [6MWT]). Directed acyclic graphs were used to identify potential confounders and specify variables to be included in the models to minimize bias. Three classes of potential confounders were included in the analysis, sociodemographic and clinical variables, medications used at admission, and exercise related variables.

Results: The average exercise minutes/week was 109.4±66.1 among atorvastatin and 106.7±49.1 among rosuvastatin users. Interaction models suggested a higher number of exercise minutes/week was more favorable among atorvastatin users on total cholesterol and LDL (0.004, 95% CI: 0.001, 0.008 and 0.004, 95% CI: 0.001, 0.007, respectively), but did not reach significance for HDL and triglycerides. Rosuvastatin use was associated with greater increases in 6MWT, however we observed no between-group differences in interaction estimates by type of statin used.

Conclusions: Rosuvastatin use could blunt the beneficial effect of exercise on LDL and total cholesterol compared to atorvastatin. No significant differences were observed in triglycerides, HDL and functional capacity levels. Additional studies are warranted with randomized treatments and larger samples. Healthcare providers should continue prescribing statins alongside recommending exercise modalities, with a careful follow-up for rosuvastatin users.

4214 | Efficacy and safety of antithrombotic therapy in atrial fibrillation patients undergoing percutaneous coronary intervention with stent or concomitant acute coronary syndrome

Han-Hsin Chueh, Shih-Tsung Huang and Fei-Yuan Hsiao

National Taiwan University, Taipei City, Taiwan

Background: For atrial fibrillation (AF) patients undergoing percutaneous coronary intervention (PCI) with stent or concomitant acute coronary syndrome (ACS), dual antiplatelet and anticoagulant might be warranted to prevent cardiovascular events and stroke. However, the optimal strategy of antithrombotic medication in "real-world" practice are not well studied in Asian population.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To compare major adverse cardiovascular event (MACE) and bleeding risk among different antithrombotic regimens.

Methods: We conducted a retrospective cohort study by using National Health Insurance Research Database (NHIRD) in Taiwan. Non-valvular AF patients who newly underwent PCI with stents or hospitalized due to ACS in 2007 to 2016 were included. Patients who received PCI, coronary artery bypass graft (CABG) or hospitalized for ACS one year before inclusion were excluded. The cohort was followed until MACE or bleeding events occurred, one year after discharge, or switched to different antithrombotic regimen. All prescriptions of antithrombotic therapy received by our study cohort were captured monthly and categorized into five groups: single antiplatelet (SAPT), single anticoagulant (SAC), dual antiplatelet (DAPT), SAPT +SAC (double) and DAPT+SAC (triple). Multivariable Cox proportional hazard model was used to compare 3-point MACE consisting of myocardial infarction, ischemic stroke and death from cardiovascular causes, all-cause mortality and major bleeding risk of aforementioned antithrombotic regimens.

Results: We identified 11,492 patients (mean age 71.7, SD=10.9; male 68.5%). Among them, the median CHA_2DS_2-VASc score is 3 (IQR 2-4), and 80.4% has a score ≥2 (≥3 if female). At discharge, most (60.75%) of the patients received DAPT as initial antithrombotic regimen, followed by SAPT (23.72%), triple (6.33%), double (6.01%) and SAC (3.19%). As compared with DAPT, there is no significant difference in 3-point MACE among other four antithrombotic regimens (SAPT: adjusted HR 1.02 [95% CI 0.85-1.32]; SAC: 0.55 [0.29-1.02]; double: 0.71 [0.47-1.07]; triple: 0.87 [0.56-1.37]. On the other hand, SAPT significantly reduced the risk of major bleeding (0.47 [0.30-0.73]), while triple therapy was associated with a nearly two-fold risk of bleeding (1.96 [1.21-3.16]).

Conclusions: Our study found that there were comparable risks of 3-point MACE among the five antithrombotic regimens (SAPT, SAC, DAPT, double and triple) identified. However, triple therapy was associated with a higher risk of major bleeding.

4230 | Comparison of effectiveness and safety between glecaprevir/pibrentasvir and sofosbuvir/velpatasvir in patients with chronic hepatitis C - A multi-institutional cohort study in Taiwan

Mu-Hsuan Hou[1], Shih-Chieh Shao[1,2], Hui-Yu Chen[3], Yuk-Ying Chan[4] and Edward Chia-Cheng Lai[2]

[1]Keelung Chang Gung Memorial Hospital, Keelung, Taiwan; [2]National Cheng Kung University, Tainan, Taiwan; [3]Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; [4]Chang Gung Medical Foundation, Taoyuan, Taiwan

Background: Pangenotypic direct-acting antiviral agents (DAA), glecaprevir/pibrentasvir (GLE/PIB) and sofosbuvir/velpatasvir (SOF/VEL), have been proven in clinical trials to be effective for chronic hepatitis C (CHC) infection. However, evidence comparing the effectiveness and safety of GLE/PIB vs. SOF/VEL is lacking.

Objectives: To compare the real-world effectiveness and safety between GLE/PIB and SOF/VEL in CHC patients.

Methods: We conducted a retrospective cohort study using the Chang Gung Research Database, which includes about 13% of CHC patients receiving DAA treatment in Taiwan. We included CHC patients without compensated liver cirrhosis newly initiating GLE/PIB or SOF/VEL between June 1, 2019 and September 31, 2019, and excluded patients without virology analyses before or after DAA treatment (n=20). We compared the rate of undetectable serum HCV RNA at the end of treatment (EOTR) as the effectiveness rate between GLE/PIB and SOF/VEL new users. The safety outcome included the elevation of liver enzymes during the GLE/PIB or SOF/VEL treatment, defined by alanine aminotransferase (ALT) reaching ≥3X upper limit of normal (ULN) or total bilirubin ≥2X ULN. We followed patients from the initiations of GLE/PIB or SOF/VEL to December 31, 2019.

Results: We identified a total of 528 CHC patients newly initiating GLE/PIB (n=247; 51.0% female; 68.4% genotype 2; 11.7% cirrhosis) and SOF/VEL (n=281; 49.0% female; 50.8% genotype 2; 21.3% cirrhosis). The mean age was 59.6 (SD 13.1) and 63.4 (SD 13.8) years old for GLE/PIB and SOF/VEL new users, respectively. The baseline mean serum HCV RNA level before treatment was 3.8 million IU/mL (SD 7.5) for GLE/PIB and 3.1 million IU/mL (SD 7.5) for SOF/VEL users. GLE/PIB and SOF/VEL had similar EOTR rates (99.5% vs. 99.6%). Patients receiving GLE/PIB had similar incidence rates of elevated ALT ≥3X ULN (1.2% vs. 1.4%), but higher rates of elevated total bilirubin ≥2X ULN (4.5% vs. 0.4%) than those receiving SOF/VEL.

Conclusions: The real-world effectiveness of GLE/PIB and SOF/VEL was comparable, based on evaluation of EOTR rate, but GLE/PIB may be associated with higher rates of elevated total bilirubin levels, compared to SOF/VEL. Our findings provide an important ground for future head-to-head studies evaluating the clinical effects among different pangenotypic DAA.

4234 | Real-world effectiveness of mood stabilizer use in persons with schizophrenia

Arto Puranen[1,2], Marjaana Koponen[2,3], Lähteenvuo Markku[1], Antti Tanskanen[1,4], Jari Tiihonen[1,4,5] and Heidi Taipale[1,2,4]

[1]Niuvanniemi Hospital, Kuopio, Finland; [2]University of Eastern Finland, Kuopio, Finland; [3]Monash Univeristy, Parkville, Australia; [4]Karolinska Institutet, Stockholm, Sweden; [5]Center for Psychiatry Research, Stockholm City Council, Stockholm, Sweden

Background: Information regarding the real-world effectiveness of mood stabilizer (MS) use in persons with schizophrenia is important, since these medications are often used as adjunctive medication in this population.

Objectives: The objective of this study was to investigate the real-world effectiveness of mood stabilizer use in persons with schizophrenia.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This retrospective cohort study used combined data from nationwide Finnish registers. The study cohort included all persons treated in inpatient care due to schizophrenia during 1972-2014 in Finland (N=61,889). Drug purchase data were obtained from the national Prescription register, and then modelled with PRE2DUP method. The follow-up period covered the years 1996-2017. Mood stabilizers in this study included carbamazepine, valproic acid, lamotrigine and lithium. Main outcome was psychiatric rehospitalization, defined as a hospitalization with psychosis (ICD-10: F20-29) as the main diagnosis. Within-individual design was used to compare the risk of outcome between time periods of MS use and non-use within the same person. Stratified COX regression analyses were utilized in calculating hazard ratios (HR) with 95% confidence intervals (CIs).

Results: Mean age of the study population was 46.2 years (SD 16.0) and 50.3% were males. During the follow-up (maximum of 22 years, mean 14.0 [SD 7.3]) 28.1% (N=17,370) of the study cohort used mood stabilizers, valproic acid being the most often used MS (16.9%, N=10,483). Risk of psychiatric re-hospitalization was lower during MS use than non-use (incidence rate 3.04 events per 10 person-years, aHR 0.88, 95% CI 0.86-0.90). Use of lithium (HR 0.84, 95% CI 0.81-0.88), valproic acid (HR 0.87, 95% CI 0.85-0.90), and lamotrigine (HR 0.90, 95% CI 0.85-0.95) were associated with lower risk of psychiatric rehospitalization compared with non-use, whereas carbamazepine use was not (HR 0.97, 95% CI 0.92-1.03).

Conclusions: Mood stabilizers are relatively often used as adjunctive treatments in schizophrenia and their use was associated with a decreased risk of psychiatric rehospitalization, which is a marker of relapse in schizophrenia.

4238 | Midodrine for prevention of intradialytic hypotension in high risk patients at a tertiary referral hospital: A retrospective study

Saja Alhabardi[1], Maryam Aldhaefi[2], Mohammed Alessa[3], Maha Alammari[3], Yousef Alrajhi[3] and Rami Bustami[2]

[1]Saudi Food and Drug Authority, Riyadh, Saudi Arabia; [2]College of Pharmacy, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [3]King Abdulaziz Medical City, Pharmaceutical Care Services, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia

Background: Intradialytic hypotension (IDH) is the most common complication that is well recognized during hemodialysis. Midodrine, an oral α-1 adrenergic agonist, is the widely utilized approach to prevent IDH. However, more clinical studies are needed to validate its efficacy in prevention of IDH in high risk hemodialysis patients.

Objectives: The primary outcome measures included the identification of treatment failure, frequency of recurrent IDH, and identify the appropriate dose and frequency of midodrine.

Methods: A retrospective cohort study was approved by IRB in January 2018. The data was retrieved from the BESTCare® hospital information system. This included all medical records for adult patients with end-stage renal disease on hemodialysis, who were placed on midodrine for over a year. The variables that related to midodrine dose, frequency, and IDH risk factors were recorded for each hemodialysis session. IDH was defined as a decline in SBP by ≥20 mmHg or a decline in MAP by ≥10 mmHg. Recurrent IDH was labeled if the patient had at least three episodes of IDH.

Results: From a total of 68 screened patients' charts, 45 patients were included in the final analysis. Among them, 40.4% had an IDH that required additional interventions to restore the SBP and MAP. IDH was significant in 23 (68%) patients who had hypoalbuminemia. Moreover, recurrent IDH occurred in 16 hemodialysis patients (35.6%). The efficacy was similar among all doses of midodrine that were administered (P> 0.05). However, treatment failure and recurrent IDH were significant in the hemodialysis patients were received Midodrine only three days per week (57%, P= 0.02; 36%, P= 0.04) respectively.

Conclusions: Midodrine appears to be effective in maintaining SBP, DBP, and MAP during the hemodialysis session in patients with high IDH risk. A Long-term follow-up with presence of comparative group would be useful to evaluate the magnitude of efficacy of Midodrine in hemodialysis patients with high risk IDH.

4289 | Lithium use in patients with bipolar disorder in inpatient care and readmission: A prospective cohort study in the central Denmark region in 2015-2018

Kazi Ishtiak-Ahmed, Louise Meyer, Christiane Gasse and Søren Dinesen Østergaard

Aarhus University Hospital Psychiatry, Aarhus N, Denmark

Background: Despite lithium (Li) being considered the first line of treatment for bipolar disorder (BD), the use of Li declined in patients with BP in Denmark in 1995-2012. However, the use of Li in Danish psychiatric hospitals is still unknown.

Objectives: As part of quality assurance assessment in the Central Denmark Region (CDR), we investigated the trend of Li use among patients with BD during their 1st psychiatric admission spell (FAS). We further investigated the association between Li use and the risk of subsequent readmission (RA). Moreover, as patients' characteristics could affect the RA, we explored trajectories of Li administration across all admission spells to identify vulnerable subgroups.

Methods: We used hospital electronic healthcare records of all psychiatric hospitals/departments in CDR. We carried out a cohort study of all patients aged ≥18 with a 1st inpatient care contact (index date) due to manic episodes (ICD-10: F30) or bipolar affective disorder (F31) in 2015-18 (N=782, 56% female, mean age 46.4 years). We followed patients from the date of discharge until the 1st RA or the end of 2018, whichever came first. We identified administrations of Li (ATC code N05AN01) during the FAS in all patients with BD. We used Cox regression analysis adjusting for age, sex, hospital site, calendar year, BD sub-types at 1st contact, number of prior contacts and diagnoses within 365 days before the index date. Group-based trajectory modeling was used to explore hidden clusters in the trajectories of Li administration.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 136 (17.4%) patients were treated with Li in the FAS. Patients with and without Li treatment did not differ on baseline characteristics. The percentage of patients with Li therapy at FAS was 20.5%, 15.7%, 15.7%, and 15.8% in 2015-18, respectively. The proportion of 1st RA was slightly lower in patients with Li administrations than in patients without (39.7% vs. 41.0%). The time to 1st RA was longer in patients with Li administration than in patients without (mean: 305 vs. 222 days). The crude and adjusted hazard rate of RA was 0.89, 95% CI: 0.66-1.19 and 0.90 (0.66-1.21), respectively. Because of the low use of Li, the trajectory analyses did not yield any meaningful hidden clusters.

Conclusions: This is the first study looking at the current trend of Li use in patients with BD in inpatient care in Denmark and in relation to RA. The use of Li remained relatively stable (but low) in inpatients patients with BD in recent years, even though time to readmission was much delayed in patients using Li.

4333 | Use of thiazolidinediones and glucagon-like peptide-1 receptor agonists and the risk of non-alcoholic fatty liver disease

Johanna H.M. Driessen[1], Judith van Dalem[1], Andrea M. Burden[2], Coen D.A. Stehouwer[1], Olaf H. Klungel[3], Frank de Vries[1] and Martijn C.G.J. Brouwers[1]

[1]*Maastricht University Medical Centre, Maastricht, Netherlands;*
[2]*Institute of Pharmaceutical Sciences, ETH Zurich, Zurich, Switzerland;*
[3]*Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands*

Background: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease in Western countries. Thiazolidinediones (TZDs) and glucagon-like peptide 1 (GLP-1) receptor agonists, both drugs used in the treatment of type 2 diabetes, have demonstrated to have beneficial effects on liver histology and are therefore potential pharmacological treatment options for patients with NAFLD.

Objectives: To assess the risk of NAFLD associated with current use of TZDs compared with current use of sulphonylureas, and between GLP-1 receptor agonists compared with current use of insulin, respectively

Methods: A population-based cohort study using data from the UK Clinical Practice Research Datalink (CPRD) GOLD was conducted. All patients with at least one oral glucose lowering agent prescription (2007-2018) and aged ≥18 years were included. The date of the first glucose lowering agent prescription determined the index date. Patients were followed from the index date until the date of death, end of study, disenrollment or NAFLD, whichever came first. Follow-up time was divided into fixed intervals of 90 days. Based on the time since the most recent oral glucose lowering drug prescription an interval was classified as current (≤ 90 days) use or past (>90 days) use.

Time-dependent Cox regression models were used to compare the risk of NAFLD between current use of TZDs and current use of sulphonylureas and to compare the risk between current use of GLP1 receptor agonists and current use of insulin. Analyses were adjusted for life-style factors, comorbidities and concomitant drug use. Two sensitivity analyses were performed. First, a propensity score matched analysis was applied to estimate the risk of NAFLD comparing use of TZDs with use of sulphonylureas. Second, the risk of NAFLD was estimated using Cox regression models comparing current GLP1 receptor agonist use to current sulphonylurea use.

Results: In total 207,367 patients (mean age 61 years, 45% women, mean follow-up 5.1 years) were included. Current use of TZDs was associated with an almost 70% reduced risk of NAFLD as compared to current sulphonylurea use (adj. HR: 0.32, 95% CI 0.20-0.52). While no difference in risk of NAFLD was observed comparing current GLP-1 receptor agonist use with current insulin use (adj. HR: 1.19, 95% CI 0.88-1.59). Results remained consistent in sensitivity analyses.

Conclusions: Results of our study endorse the use of TZDs for selected patients with NAFLD and type 2 diabetes. However, our study does not support previous findings regarding the beneficial effect of GLP-1 receptor agonists on NAFLD.

4337 | Impact of multiple cardiovascular medications on mortality after an incidence of ischaemic stroke or transient ischaemic attack: A 10-year cohort study

Tiantian Ma, Ian C.K. Wong, Cate Whittlesea, Zixuan Wang, Kenneth K.C. Man, Wallis Lau, Ruth Brauer and Li Wei
UCL School of Pharmacy, London, United Kingdom

Background: Combination therapy is common in patients with ischaemic stroke or transient ischaemic attack (TIA), but the evidence is limited on its long-term effects on mortality.

Objectives: To assess the effect of multiple cardiovascular drugs on long-term survival in patients following the first diagnosis of ischaemic stroke or TIA.

Methods: A cohort study was conducted using The Health Improvement Network database from 2007 to 2016. The study included 45,072 patients aged 45 and above years with their first record of stroke or TIA. Cardiovascular drugs were categorised into groups according to the number of individual cardiovascular medicines and the number of classes of cardiovascular drugs during the first 90 days. We estimated the risk of all-cause mortality using a marginal structural model to calculate hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: During a mean follow-up of 3.7 years, there were 7,794 deaths. There were 714 patients where no drugs were prescribed, 4,434 patients with one drug, 9,646 with two drugs, 11,014 with three drugs, 9,271 with four drugs, 5,789 with five drugs and 4,204 patients with ≥ 6 drugs prescribed. The mean age was 71.8 (SD:11.6) years old. Compared with patients who were prescribed one drug only, the risk ratios of mortality (95% CIs) were 1.78 (1.61-1.97) for no drug, 0.76 (0.69-0.83) for two drugs, 0.63 (0.58-0.69) for three drugs, 0.58 (0.53-0.64) for four drugs, 0.59 (0.53-0.66) for five drugs and 0.62 (0.55-0.70) for ≥ 6 drugs. Similar results were found among the combination of different drug classes.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: The results suggest multiple drug treatment, especially combinations of four or five cardiovascular drugs can improve long-term survival after stroke of TIA.

4340 | Rationale, design and feasibility of conducting a real-world study of outcomes in patients with a history of MI receiving extended DAPT with ticagrelor 60 mg

Eva Lesén[1], Chris Hewitt[1], Evangelos Giannitsis[2], Jonatan Hedberg[1], Tomas Jernberg[3], Dimitra Lambrelli[4], Daniel Lindholm[1], Aldo P. Maggioni[5], Jennie Medin[1], Anna Schultze[4], Albert Ariza Solé[6], Robert F. Storey[7], Karolina Andersson Sundell[1], Jurrien ten Berg[8], Narinder Bhalla[1] and Marc Bonaca[9,10]

[1]AstraZeneca, Gothenburg, Sweden; [2]University of Heidelberg, Heidelberg, Germany; [3]Karolinska Institute, Solna, Sweden; [4]Evidera, London, United Kingdom; [5]ANMCO Research Center, Florence, Italy; [6]Hospital Universitari de Bellvitge, Barcelona, Spain; [7]University of Sheffield, Sheffield, United Kingdom; [8]St Antonius Hospital, Nieuwegein, Netherlands; [9]University of Colorado Anschutz, Aurora, CO; [10]CPC Clinical Research and CPC Community Health, Aurora, CO

Background: Comparative effectiveness research (CER) using real-world data is increasingly recognized to complement RCTs as a valuable support for health care decision making. However, concerns about bias and confounding in CER have been raised. A stepwise approach of understanding data and its feasibility for CER can help to avoid biased analyses.

Objectives: To assess the feasibility of 1) describing bleeding and cardiovascular (CV) outcomes in clinical practice and 2) conducting comparative analyses of dual antiplatelet therapy (DAPT) with ticagrelor 60 mg vs. low-dose aspirin alone in patients with a history of MI.

Methods: Our assessment followed the guidelines for CER according to Good ReseArch for Comparative Effectiveness (GRACE) principles. An estimated 15,000 patient-years on treatment with ticagrelor 60 mg are needed to detect an HR of 0.85 in the rate of CV death, MI or stroke vs. aspirin alone with 85% power. Seven relevant databases in Europe and US were evaluated with respect to their characteristics, population coverage and availability of data on key variables, to assess if sufficient statistical power could be achieved for well-balanced comparative analyses of bleeding and CV outcomes.

Results: The characteristics of the targeted databases will be presented along with the assumptions for the power calculations, estimated patient numbers and how requirements for CER are fulfilled. Differences between the 7 databases were identified. Some lacked complete information on all variables assumed to be needed to adequately adjust for treatment allocation bias and baseline confounding in CER, leading to potential residual confounding. Key methodological challenges for CER were identified, such as determining aspirin use, which is not captured in all databases, and defining a relevant index date for patients with continuous aspirin monotherapy. Due to these limitations, it was determined that CER could not be robustly performed and instead, a multi-national observational study is being conducted to describe rates of bleeding and CV outcomes in patients with ticagrelor 60 mg. Estimates derived from each database will be combined via meta-analysis.

Conclusions: An extensive feasibility assessment is an important step prior to conducting CER. Describing real-world bleeding and CV outcomes in patients with ticagrelor 60 mg can further support decision-making on long-term antithrombotic treatments.

4342 | Differences between randomized clinical trial participants and real-world empagliflozin users and the changes in their glycated hemoglobin levels

Nicolai E. Munk[1], Jakob S. Knudsen[1], Anton Pottegård[2], Daniel R. Witte[3,4,5] and Reimar W. Thomsen[1]

[1]Aarhus University Hospital, Aarhus, Denmark; [2]University of Southern Denmark, Odense, Denmark; [3]Aarhus University, Aarhus, Denmark; [4]Steno Diabetes Center Aarhus, Aarhus, Denmark; [5]Danish Diabetes Academy, Odense, Denmark

Background: Use of the sodium-glucose cotransporter 2 inhibitor (SGLT2i) empagliflozin has increased substantially since 2015. Little is known about characteristics of real-world patients who use empagliflozin or about empagliflozin's effectiveness in reducing glycated hemoglobin (HbA1c) levels in routine clinical care.

Objectives: To characterize real-world initiators of empagliflozin, to examine the proportion of initiators who would have been eligible for participation in phase 3 randomized clinical trials (RCTs) of empagliflozin, and to assess changes in HbA1c levels after empagliflozin initiation.

Methods: This cross-sectional study used linked population-based medical databases containing complete information on redeemed prescriptions, laboratory tests, and diagnoses for all residents in Northern Denmark. A total of 7034 residents of Denmark who filled a first-time empagliflozin prescription from January 2014 to December 2018 were included. Main outcomes were proportion of real-world users ineligible for RCT inclusion and absolute reduction in HbA1c level 6 months after empagliflozin initiation.

Results: Of 7034 first-time empagliflozin initiators (median [interquartile range] age, 61.50 [53.30-69.38] years; 4475 [63.6%] men), 3878 (55.1%) would have been ineligible for phase 3 RCT participation; frequent reasons were concurrent use of specific glucose-lowering drugs (1955 initiators [27.8%]), baseline HbA1c level outside the eligibility range (1772 [25.2%]), or presence of comorbidities (1067 initiators [15.3%]). Initiation of empagliflozin was associated with a mean HbA1c reduction of −0.91% (95%CI, −0.94% to −0.87%) after 6 months, similar to phase 3 RCT results. Real-world empagliflozin initiators who would have been eligible for RCT participation experienced slightly lower mean HbA1c reductions (−0.78%; 95%CI, −0.82% to −0.74%) compared with patients who would have been ineligible (−1.01%; 95%CI, −1.07% to −0.95%). Ineligible initiators had higher median (interquartile range) baseline HbA1c values than eligible initiators (8.5% [7.4% to 10.1%] vs 8.2% [7.6% to 9.8%]).

Conclusions: In this cross-sectional study, more than half of empagliflozin initiators exhibited clinical characteristics that would

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

have led to ineligibility for the RCTs leading to the drug's approval. While the findings suggest that the efficacy of empagliflozin in reducing HbA1c levels translates into real-world effectiveness, further studies should examine clinical outcome effectiveness and drug safety in routine clinical care.

4457 | Comparative safety of JAK inhibitors in patients with rheumatoid arthritis: A network meta-analysis of clinical trials

Carlos Alves[1,2], Diogo Mendes[2], Ana Penedones[1,2] and Francisco Batel Marques[1,2]

[1]School of Pharmacy, University of Coimbra, Coimbra, Portugal; [2]AIBILI - Association for Innovation and Biomedical Research on Light and Image, Coimbra, Portugal

Background: Janus kinases (JAKs) inhibitors act in an intracellular signalling pathway activated by pro-inflammatory cytokines involved in the pathogenesis of rheumatoid arthritis. Although JAK inhibitors are effective in reducing the symptoms of rheumatoid arthritis, they have been associated with premature discontinuation of the treatment due to adverse events.

Objectives: This study is aimed at assessing the safety of JAK inhibitors in patients with rheumatoid arthritis.

Methods: A literature search was conducted in order to identify randomized controlled trials (RCTs) evaluating the efficacy and safety of JAK inhibitors in patients with rheumatoid arthritis. The outcomes assessed were serious adverse events and adverse events leading to treatment discontinuation. Network meta-analyses were performed using STATA 13.0.. For each outcome, treatments were ranked according to the probability of being the safest (best) alternative using the surface under the cumulative ranking curve (SUCRA).

Results: Thirty-one RCTs met the inclusion criteria. No differences were observed between the treatments regarding the risk of serious adverse events. The ranking probability based on the SUCRA suggests that adalimumab is probably the safest treatment (SUCRA=0.811), followed by methotrexate (SUCRA=0.666) and baricitinib (SUCRA=0.657) [SUCRAs for remaining drugs; placebo=0.569; peficitinib=0.544; tofacitinib=0.542; filgotinib=0.310; upadacinitib=0.279; etanercept= 0.123]. Upadacitinib increases the risk of adverse events leading to discontinuation compared to placebo (1.43; 95%CI 1.16 - 1.75), to baricitinib (1.54; 95%CI 1.04 - 2.30) and to tofacitinib (1.36; 95%CI 1.05 to 1.74). The ranking probability based on the SUCRA suggests that baricitinib is probably the safest treatment (SUCRA=0.831), followed by placebo (SUCRA=0.791) and tofacitinib (SUCRA=0.656) [SUCRAs for remaining drugs; peficitinib=0.559; filgotinib=0.463; etanercept=0.411; adalimumab = 0.391; methotrexate=0.305; upadacitinib=0.092].

Conclusions: In patients with rheumatoid arthritis, JAK inhibitors were not associated with a significant risk of serious adverse events. However, upadacitinib slightly increases the risk of adverse events leading to treatment discontinuation when compared to baricitinib and tofacitinib.

4461 | Comparative risk of infections among JAK inhibitors used in rheumatoid arthritis: A network meta-analysis of clinical trials

Carlos Alves[1,2], Diogo Mendes[2], Ana Penedones[1,2] and Francisco Batel Marques[1,2]

[1]School of Pharmacy, University of Coimbra, Coimbra, Portugal; [2]AIBILI - Association for Innovation and Biomedical Research on Light and Image, Coimbra, Portugal

Background: The Janus kinases (JAKs) are cytoplasmic tyrosine kinases associated with membrane cytokine receptors that mediate signalling of multiple cytokines and growth factors, contributing to the pathogenesis of multiple autoimmune disorders. JAK inhibitors are a new class of targeted therapies that improve the symptoms of rheumatoid arthritis, but have been with an increased risk of infections.

Objectives: This study is aimed at assessing the risk of tuberculosis and the risk of herpes zoster infection associated with JAK inhibitors in patients with rheumatoid arthritis.

Methods: A literature search was conducted in order to identify randomized controlled trials (RCTs) evaluating the efficacy and safety of JAK inhibitors in patients with rheumatoid arthritis. The outcomes assessed were the risk of tuberculosis and the risk of herpes zoster infection. Network meta-analyses were performed using STATA 13.0.. For each outcome, treatments were ranked according to the probability of being the safest (best) alternative using the surface under the cumulative ranking curve (SUCRA).

Results: Thirty-one RCTs met the inclusion criteria. Filgotinib has a reduced risk of herpes zoster when compared to adalimumab (0.24; 95%CI 0.06 - 0.89), etanercept (0.19; 95%CI 0.05 - 0.75), peficitinib (0.15; 95%CI 0.03 - 0.80) and tofacitinib (0.25, 95%CI 0.08 - 0.81). The ranking probability based on the SUCRA suggests that filgotinib is probably the safest treatment (SUCRA=0.945), followed by placebo (SUCRA=0.715) and baricitinib (SUCRA=0.619) [SUCRAs for remaining drugs; upadacitinib=0.481; tofacitinib=0.437; methotrexate=0.424; adalimumab=0.400; etanercept=0.296; peficitinib=0.184]. No differences were observed between the treatments regarding the risk of tuberculosis. The ranking probability based on the SUCRA suggests that baricitinib is probably the safest treatment (SUCRA=0.811), followed by methotrexate (SUCRA=0.571) and upadacitinib (SUCRA=0.446) [SUCRAs for remaining drugs; placebo=0.441; tofacitinib=0.437; filgotinib=0.437; adalimumab=0.356].

Conclusions: The results suggest that filgotinib may have the lower the risk of herpes zoster infection among the drug evaluated. Evidence also suggests that the risk of tuberculosis among JAK inhibitors may be comparable.

4498 | Ascertainment of schizophrenia relapse and impact on the comparative effectiveness of oral versus injectable antipsychotics in the real-world setting: A systematic review

Tiffany Cristarella[1,2], Mareva Faure[2], Genaro Castillon[2], Jean-François Nepveu[1,2] and Yola Moride[1,2,3]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]Faculty of Pharmacy, University of Montreal, Montreal, QC, Canada; [2]YOLARX Consultants, Montreal, QC, Canada; [3]Center for Pharmacoepidemiology and Treatment Science, Rutgers, The State University of New Jersey, New Brunswick, NJ

Background: Relapse of schizophrenia symptoms is frequent, with non-adherence to oral antipsychotics (OAPs) being a major contributor. Long-acting injectables (LAIs) are considered an important treatment option in improving adherence and thus, preventing relapse. Comparative effectiveness data on OAPs and LAIs in the real-world (RW) setting remain conflicting. It is hypothesized that absence of a universally accepted definition for schizophrenia relapse is a source of heterogeneity, which hampers comparability between studies.

Objectives: To identify criteria used to define schizophrenia relapse in comparative effectiveness studies of OAPs and LAIs, and to evaluate the impact of such definitions on comparative effectiveness estimates.

Methods: A systematic review of comparative effectiveness studies in the RW setting was conducted using MEDLINE and Embase between 2013 and 2019. Searches of the grey literature were conducted to identify additional sources. Studies that compared effectiveness of OAPs and LAIs in schizophrenia patients and, that reported relapse-related outcomes were independently screened by two assessors, with conflicts resolved by a third.

Results: Of the 543 sources identified, 52 individual studies and 17 reviews were found. Four main schizophrenia relapse definitions were identified: i) schizophrenia-related hospitalization (specific to symptoms of schizophrenia), ii) psychiatric hospitalization (overall psychotic, mental/behavioural disorders), iii) hospitalization associated with recurrence of significant psychotic symptoms, dangerous/violent behaviour, deteriorated functioning, or inadequate response to outpatient treatment, and, iv) schizophrenia-related emergency room (ER) visit. However, in the majority of studies (60%), there was no operational definition of relapse. Inconsistent results depending on the definition of relapse were found, where LAIs were superior to OAPs in reducing the risk of schizophrenia-related hospitalization, while no difference was observed in reducing the risk of schizophrenia-related ER visits.

Conclusions: This systematic review confirms that there is no universal definition of schizophrenia relapse in RW studies, which leads to heterogeneity in comparative effectiveness estimates. The quantitative impact of relapse definitions on comparative effectiveness estimates will be presented, using a meta-regression analysis.

4506 | Use of glycolysis enhancing medications is associated with a decreased risk of developing Parkinson's disease

Jacob E. Simmering[1], Nandakumar Narayanan[1], Lei Liu[2], Michael J. Welsh[1] and Anton Pottegård[3]

[1]Carver College of Medicine University of Iowa, Iowa City, IA; [2]Capital Medical University, Beijing, China; [3]University of Southern Denmark, Odense, Denmark

Background: Impaired energy metabolism has been implicated in the pathogenesis of Parkinson's disease (PD). Prior work has suggested the commonly used α1-adrenergic receptor antagonists terazosin (Tz), alfuzosin (Az), and doxazosin (Dz) bind to phosphoglycerate kinase 1, a key enzyme in metabolism, and increase levels of ATP. Animal models of PD suggest that use of Tz/Dz/Az increases ATP levels in the brain and dopamine neurons, thus slowing or preventing development PD.

Objectives: To assess the association between use of Tz/Dz/Az and risk of PD.

Methods: We conducted two independent cohort studies using the Truven Marketscan Database in the US and Danish nationwide health registries. We identified new users of Tz/Dz/Az as well as new users of tamsulosin. Tamsulosin is a medication with a similar indication and use but is structurally unrelated to Tz/Dz/Az and does not promote metabolism, making it an attractive active comparator. We propensity score matched PD-free new users of Tz/Dz/Az and tamsulosin accounting for age, comorbidities, healthcare utilization, and, in the case of Truven, enrollment duration. Followup started 365 days after medication start and continued until the individual developed PD or was censored. Development of PD was defined as starting medications for PD or having a diagnosis of PD. Risk of PD was assessed using Cox proportional hazards regression. A Cox model with time-varying hazard ratios based on the cumulative dose in daily defined doses (DDD) was estimated to determine if a dose response pattern was present.

Results: Overall, the hazard of developing PD for Danish users of Tz/Dz/Az was 11% lower (95% CI: 2% to 19%) compared to users of tamsulosin while the reduction was 25% (95% CI: 18% to 31%) in the US database. A dose response pattern was observed in both databases: short use (1 to 499 DDD) had a HR of 0.94 (95% CI: 0.83 to 1.06) in the Danish database and 0.87 (95% CI: 0.77 to 0.97) in Truven while the longest term use (over 2,000 DDD) had a HR of 0.79 (95% CI: 0.65 to 0.95) and 0.46 (95% CI: 0.34 to 0.60) in the respective databases.

Conclusions: Users of Tz/Dz/Az have lower hazard of developing PD than users of an active comparator, tamsulosin. This result is observed in two different data sources from two different countries and exhibits a dose response relationship with longer duration of therapy having a greater protective effect.

4517 | Hypothetical intervention of sodium-glucose cotransporter-2 inhibitors on renal outcome in type 2 diabetes

Masato Takeuchi and Koji Kawakami

Kyoto University, Kyoto, Japan

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are the latest class of diabetic medications. Although we recently demonstrated that SGLT2i exert superior renoprotective effects to other classes of diabetic medications in the real-world context, there were two limitations in our analysis; the observation period was short (median: 17 months) and we did not fully account for the time-varying nature of drug regimen.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To estimate the effect of SGLT2i exposure on renal outcome using a parametric g-formula.

Methods: We used the RWD database, an electronic database of healthcare records in Japan, comprising data from approximately 20 million patients from approximately 160 medical institutions. Prevalent users of diabetic medications in April, 2014 were eligible for the study, but patients with type 1 diabetes, <19 years of age, or with end-stage renal disease at baseline (defined by estimated glomerular filtration rate [eGFR]< 30 mL/1.73 m2/min) were excluded. The primary endpoint was the composite of renal deterioration (>40% decline in eGFR) and the development of eGFR<30 mL/1.73 m2/min. We estimated the risk of the occurrence of the composite renal endpoint for the hypothetical SGLT2i exposure scenario of "always treat". The computation used the g-formula framework, with R statistical environment. Age and sex were used as time-fixed covariates, and glycemic control and exposure histories to other diabetic medication were adjusted as time-varying covariates.

Results: Data from 9449 patients were analyzed, of whom 1031 patients were exposed at least once to SGLT2i. The median age of this cohort was 70 years, and male patients accounted for 61%. In the "natural course" scenario, 16.7 % of patients reached the primary endpoint at 56 months, almost identical to the observed data (16.7%); this ensures that the chance of our model misspecification was limited. In contrast, the composite endpoint was expected to occur in 7.5% in "always treat" scenario. The risk difference between two scenarios was 9.3%, with 95% confidence interval of 3.3-13.6%.

Conclusions: In comparison with the "natural course" scenario or the observed data, the hypothetical intervention of SGLT2i was associated with a risk reduction of the renal endpoint by 9.3% at ~5 years of drug therapy.

4522 | Comparative effectiveness of amoxicillin-clavulanate versus metronidazole and a fluoroquinolone on hospital admission risk among outpatient diverticulitis patients in the United States, 2000-2005

Charles E. Gaber, Anne F. Peery, Jessie K. Edwards, Jennifer L. Lund, Til Stürmer, Sharon Peacock-Hinton, Robert S. Sandler and Alan C. Kinlaw

University of North Carolina-Chapel Hill, Chapel Hill, NC

Background: Acute diverticulitis is most commonly treated in the outpatient setting with either amoxicillin-clavulanate or a combination of metronidazole and a fluoroquinolone. Despite being commonly prescribed for diverticulitis, the effect of these antibiotics on long-term outcomes remains uncertain.

Objectives: To determine hospital admission risk in diverticulitis patients treated with amoxicillin-clavulanate versus a combination of metronidazole and a fluoroquinolone.

Methods: We used administrative claims data from Medicare (2006-2015) and IBM Watson Health MarketScan (2000-2015) to conduct active-comparator, new-user cohort studies in patients with incident outpatient diverticulitis who initiated amoxicillin-clavulanate versus a combination of metronidazole and a fluoroquinolone. We estimated 1-year risk of hospital admission for diverticulitis with 95% confidence intervals (CI), using the Aalen-Johansen estimator to account for the competing risk of death (in the Medicare cohort). We implemented inverse probability of treatment weights to control for confounding by baseline variables.

Results: The Medicare cohort included 19,787 individuals with diverticulitis in the outpatient setting who filled prescriptions for either amoxicillin-clavulanate (n=2,645) or metronidazole and a fluoroquinolone (n=17,142). The one-year risk of admission amongst amoxicillin-clavulanate initiators was 2.7% (95% CI: 2.0, 3.4), compared to 3.3% (95% CI: 3.1, 3.6) in metronidazole + fluoroquinolone initiators (adjusted risk difference = -0.7%, 95%: -1.4, 0.1). The MarketScan cohort included 89,824 individuals with diverticulitis in the outpatient setting who filled prescriptions for either amoxicillin-clavulanate (n=9,073) or metronidazole and a fluoroquinolone (n=80,751). The one-year risk of inpatient admission amongst amoxicillin-clavulanate initiators was 3.3% (95% CI: 2.9, 3.7), compared to 3.9% (95% CI: 3.8, 4.0) in metronidazole + fluoroquinolone initiators (adjusted risk difference = -0.6%, 95%: -1.0, -0.2).

Conclusions: In this analysis of administrative claims from Medicare and commercial plans, we found that amoxicillin-clavulanate was associated with decreased risk of hospital admission compared to metronidazole and a fluoroquinolone. Further research will assess additional effectiveness endpoints, the regimens' comparative safety, and treatment effect heterogeneity by immunosuppression status.

4546 | Persistence to bone targeting agents in patients with bone metastases from solid tumors in Hong Kong, Korea, and Taiwan

Chin-Yao Shen[1], Philip Chun-Ming Au[2], Yeon-Hee Baek[3], Ching-Lung Cheung[2], Wei-Pang Chung[4], Seasea Nan Gao[5], Yea-Huei Kao Yang[1], Nora Kleinman[5], Ju Hwan Kim[3], Jeff Lange[6], Tzu-Chi Liao[1], Tzu-Chieh Lin[6], Ju-Young Shin[3], Chor-Wing Sing[2], Ian Chi Kei Wong[2] and Edward Chia-Cheng Lai[1,7]

[1]School of Pharmacy, Institute of Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [2]Department of Pharmacology and Pharmacy, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [3]School of Pharmacy, SungKyunKwan University, Suwon, Republic of Korea; [4]Division of Hemato-Oncology, Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [5]Amgen Asia Holdings Limited, Hong Kong, Hong Kong; [6]Amgen Inc., Thousand Oaks, CA; [7]Department of Pharmacy, National Cheng Kung University Hospital, Tainan, Taiwan

Background: Bone targeting agents (BTAs) are used to prevent skeletal-related events in patients with bone metastases from solid tumors. Persistence is a construct expected to correlate with expectations of therapy benefits, risks, and tolerability.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To compare persistence to denosumab (D), zoledronic acid (Z), and pamidronate (P) among patients with bone metastasis from solid tumors.

Methods: This population-based retrospective cohort study included patients from electronic health records in Hong Kong (HK, 2013-2017) and national claims databases in Korea (KR, 2012-2016) and Taiwan (TW, 2013-2017). Inclusion criteria were adult patients with breast, lung, or prostate cancer; and initiation of BTA after metastases diagnosis. The primary outcome was persistence by BTA type, from treatment initiation to interruption (switching or discontinuation, defined as no treatment within 90 days). Patients were censored at death or study end. Risk of treatment interruption by BTA type was compared with Cox-proportional hazard models adjusted for age, sex and other clinical covariates.

Results: The study included 883 (D:458, Z:357, P:68) patients from HK, 4800 (Z:4068, P:732) from KR, and 5127 (D:3440, Z:1210, P:477) from TW. Denosumab was unavailable in KR during the study period. The proportion of lung, breast and prostate cancer were similar between HK (39%, 43%, 18%) and TW (36%, 42%, 22%) while KR differed (8%, 73%, 19%). For all tumor types in HK, persistence was longer in denosumab users (median, 219 days; Interquartile Range (IQR), 132-451 days) and zoledronic acid users (163 days; IQR, 90-236 days) relative to pamidronate users (90 days; IQR, 90-124 days). For all tumor types in TW, persistence was longer in denosumab users and zoledronic acid users relative to pamidronate users (D: 188 days; 111-342 days, Z: 173 days; 90-334 days, P: 111 days; 90-169 days). For all tumor types in KR, persistence was longer in zoledronic acid users relative to pamidronate users (Z: 240 days; 145-409 days and P: 124 days; 90-208 days). Relative to denosumab users, treatment interruption was more likely in both pamidronate users (adjusted hazard ratio (aHR) 3.1 [95% CI 1.8-5.1] in HK and 3.1 [95% CI 2.6-3.6] in TW) and zoledronic acid users (aHR 2.8 [95% CI 2.2-3.6] in HK and 2.3 [95% CI 2.1-2.6] in TW). Results were consistent for analyses stratified by tumor type.

Conclusions: Patients were persistent to denosumab longer than to other BTAs, although there was a wide range of persistence to BTAs. Clinical significance of this variation in persistence in real-world clinical practice warrants subsequent study.

4576 | Genetic alternations correlated with resistant to abiraterone and enzalutamide in metastatic prostate cancer

Yu-Hsuan Joni Shao[1], Tzu-Hung Hsiao[2] and Yen-Chuan Ou[3]
[1]Taipei Medical University, Taipei, Taiwan; [2]Taichung Veterans General Hospital, Taichuang, Taiwan; [3]Tung's Taichung MetroHarbor Hospital, Taichung, Taiwan

Background: Heterogeneity in the genomic landscape of metastatic castration resistant prostate cancer (mCRPC) has become apparent through several comprehensive profiling studies, but little is known about the impact of this heterogeneity on clinical outcome especially following new generation androgen receptor directed therapy (ARDT), abiraterone or enzalutamide.

Objectives: To examine the association of germline and somatic mutations with disease progression in mCRPC patients treated with new generation of ARDT.

Methods: A prospective cohort including patients with mCRPC were enrolled between 2016 and 2019 in three medical centers in Taiwan. A total of 84 patients received ARDT were selected. Blood was collected before therapies—enzalutamide (n = 36) or abiraterone (n = 48). We performed whole exome sequencing on 84 blood derived DNA samples from patients as well as next-generation sequencing to analyze cfDNA using QIAseq™ Targeted DNA Panels and Human Comprehensive Cancer Panel. Cancer stage, clinical characteristics and prostate specific antigen (PSA) were collected through electronic medical records before treatment and during follow-up. Primary end points were prostate-specific antigen response, and prostate cancer antigen progression-free survival (PFS).

Results: The median PFS time was 28.9 weeks (Interquartile range 48.4 weeks) in our population. Germline DNA repair genes mutations were not significantly associated with PFS following treatments. The adjusted hazard ratio (aHR) was 0.87 (95% confidence interval [CI] 0.52-1.45) in patients who did not carry any germline DNA repair genes mutations comparing with those with mutations after adjusting for baseline PSA and drug type. In contrast, comparing to patients carried somatic mutations, those without somatic mutations are associated with an improved progression free survival with an aHR of 0.44 (95% CI:0.21-0.94) after adjusting for baseline PSA.

Conclusions: This analysis integrating mCRPC genomics with histology and clinical outcomes identifies somatic genomic alteration as a potent predictor of poor outcome, and with great potential to understand therapeutic resistant of mCRPC.

4602 | Non-vitamin K antagonist oral anticoagulant and proton-pump inhibitor cotreatment and the association with upper gastrointestinal bleeds in patients with atrial fibrillation: A multi-database cohort study

Joris Komen[1], Anton Pottegård[2], Tomas Forslund[3], Aukje Mantel-Teeuwisse[1], Björn Wettermark[4], Maja Hellfritzsch[2], Jesper Hallas[2], Lisa Smits[5], Ron Herings[5], Paul Hjemdahl[3] and Olaf Klungel[1]
[1]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands; [2]Department of Public Health, University of Southern Denmark, Odense, Denmark; [3]Clinical Epidemiology/Clinical Pharmacology, Karolinska Institutet, Stockholm, Sweden; [4]Uppsala University, Uppsala, Sweden; [5]PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands

Background: Non-vitamin K antagonist oral anticoagulants (NOAC) reduce the risk of stroke in patients with atrial fibrillation (AF), but increase the risk for upper gastrointestinal bleeding (UGIB). Proton pump inhibitors (PPIs) may reduce this risk, but guidelines are inconclusive whether to recommend PPI cotreatment in NOAC treated patients.

Objectives: To assess the association between PPI use and UGIB in AF patients treated with a NOAC.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We used a common data model to select all AF patients initiated on a NOAC between April 2011 and July 2018 in the Swedish Stockholm Healthcare database, the Danish National registries, and the Dutch PHARMO database. Patients were followed until they stopped NOAC treatment, moved out of the region/database, died, or suffered an UGIB. The outcome of interest was an UGIB diagnosed in a secondary care inpatient setting. We used time-varying inverse probability weighted (IPW) Poisson regression to calculate incidence rate ratios (IRRs), contrasting PPI use to no PPI use periods, taking age, sex, 20 comorbidities, and 13 comedications into account. Comorbidities and comedications were risk factors for UGIB. We used fixed effects meta-analyses to pool the results. We analyzed non GI major bleeds and lower GI major bleeds as non-PPI related falsification endpoints.

Results: In 161 872 patients, with 283 619 years of follow-up and 50 402 years of PPI exposure, 781 patients suffered from a UGIB (IR: 27.5/10 000py). Patients receiving PPIs were older, had more comorbidities, and received more comedication in all three databases. Taking IPW into account, all databases showed similar trends toward protective effects of PPI treatment on UGIB, with IRRs of 0.75 in Stockholm (95% confidence interval (CI): 0.47 - 1.19), 0.79 in Denmark (CI: 0.59 - 1.05) and 0.73 in PHARMO (CI: 0.40 - 1.32). The meta-analysis showed a significant risk reduction during PPI treatment (IRR: 0.77; CI: 0.61 - 0.96). We found a null association between PPI use and non-GI major bleeds, but a significantly increased risk for lower GI bleeds during PPI cotreatment (non-GI IRR: 1.08; CI: 0.93 - 1.26, lower GI IRR: 1.40; CI: 1.25 - 1.57).

Conclusions: Concomitant use of a PPI in NOAC treated AF patients was associated with a reduced risk for UGIB. One falsification endpoint analysis showed potential residual confounding, which indicates that the true protective effect might be even larger. In the absence of randomized trial data, these results indicate that PPI cotherapy might be beneficial for UGIB prevention in these patients.

4641 | No added benefit of benzodiazepines to antidepressant monotherapy on mortality in patients with depression

Han Eol Jeong[1], Woo Jung Kim[2,3], In-Sun Oh[1], Ha-Lim Jeon[1] and Ju-Young Shin[1]

[1]Sungkyunkwan University (SKKU), Suwon, Republic of Korea; [2]Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, Republic of Korea; [3]Gyeonggi Provincial Dementia Center, Suwon, Republic of Korea

Background: With antidepressants (AD) having minimal therapeutic effects during its initial weeks of treatment, benzodiazepines (BZD) are used concomitantly to alleviate depression symptoms. However, the safety associated with prolonged BZD use with ADs and mortality in patients with depression is yet to be evaluated.

Objectives: To evaluate the risk of mortality associated with concomitant AD plus BZD therapy (AD+BZD), or concomitant therapy of two AD classes (AD+AD), compared to AD monotherapy among patients with depression.

Methods: We conducted a cohort study using Korea's nationwide healthcare database from 2002 to 2017. We defined our cohort as those without a depression diagnosis, and prescriptions for ADs or BZDs in the two years prior to their incident date of depression diagnosis (cohort entry). Exposure was defined using an intention-to-treat approach and classified into three groups: AD, AD+AD, and AD+BZD, with follow-up starting on their incident AD prescription within six months of depression diagnosis. Our primary and secondary outcomes were mortality and hospitalizations, respectively, with patients censored on the earliest of outcome, 1-year of follow-up, or end of study. To balance baseline characteristics, we matched 1:1:1 using propensity score, estimated using multivariate logistic regression. A multivariable Cox proportional hazards model was used to estimate hazards ratios (HR) with 95% confidence intervals (CI), adjusting for various confounders.

Results: The matched cohort had 44,052 patients with 14,684 patients in each treatment group. Compared to patients receiving AD monotherapy, AD+BZD therapy was associated with an increased risk of mortality (HR 1.71, 95% CI 1.33-2.20), while AD+AD therapy had a null association (1.26, 0.97-1.63). Risk of hospitalization was moderately increased with AD+AD (1.11, 1.05-1.18) and AD+BZD (1.10, 1.03-1.17) therapy. Despite stratifying for sex, risk of mortality remained elevated for AD+BZD therapy, with a higher risk in males (1.98, 1.40-2.80) than females (1.44, 1.02-2.03). Risk was not increased with AD+AD therapy. For age-stratified analysis, only AD +BZD therapy increased the risk of mortality in those aged <65 years (2.83, 1.92-4.19), whereas both types of concomitant therapies did not increase the risk of mortality in those aged ≥65 years.

Conclusions: Our study found no overall added benefit of BZDs on AD monotherapy as its concomitant use was associated with an increased risk of mortality, especially in those aged <65 years. This signals clinicians to take precaution when co-prescribing BZDs with ADs in treating depression.

4648 | The impact of childhood pneumococcal conjugate vaccine immunisation on pneumonia admissions in Hong Kong: A population-based interrupted time series analysis from 2004-2017

Min Fan[1], Qiuyan Yu[1], Hong Qiu[2] and Xue Li[1,3,4]

[1]Centre for Safe Medication Practice and Research, Department of Pharmacology and Pharmacy, University of Hong Kong, Hong Kong, Hong Kong; [2]Institute of Environment, Energy and Sustainability, Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Department of Paediatrics and Adolescent Medicine, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong; [4]Department of Social Work and Social Administration, Faculty of Social Sciences, University of Hong Kong, Hong Kong, Hong Kong

Background: Nine years after its introduction in the US, PCV was introduced to Hong Kong (HK) childhood immunisation program in September 2009; however, the burden of pneumonia remains high in the post-PCV period. It is important to investigate the herd immunity

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of childhood PCV immunisation on pneumonia hospitalization to inform further vaccination policies.

Objectives: To evaluate changes in all-cause pneumonia admissions following the introduction of childhood PCV immunisation in HK, using interrupted time series (ITS) analysis.

Methods: In this population-based study quasi-experimental study, we used Clinical Data Analysis and Reporting System (CDARS), which contains the electronic medical records of all public hospitals in HK, to evaluate the vaccine effect. We identified target patients with a principal diagnosis of all-cause pneumonia between 2004 and 2017 and applied segmented quasi-Poisson regression model to estimate the change of pneumonia admission after the childhood PCV introduction. Whereas there was an H1N1 pandemic during 2009-2011 in HK, we decided to take January 2012 as the intervention time point to minimize the potential bias associated with the influenza outbreak. Subgroup analysis was conducted by dividing age into seven groups.

Results: From 2004 to 2017, the monthly age-standardised incidence of pneumonia admission fluctuated between 2.83 and 7.47 per 10,000 persons. There was a marginal significant decrease in the trend of all-cause pneumonia admission after PCV13 introduction (incidence rate ratio: 0.997, 95% CI: 0.995, 0.999). We also observed a similar decreasing trend in older adults aged 75 years or above but not the younger age groups.

Conclusions: After the introduction of childhood PCV13 immunization, there is a significant reduction in pneumonia admission among the overall population in HK. The herd immunity of childhood PCV13 immunisation was determined in older adults. Future study should investigate the long-term effect of PCV immunization under the circumstance of possible serotype replacement upon the vaccine introduction.

4725 | Sex disparities in the effect of statins on lipid parameters: The PharmLines initiative

Nicholas Byron Hunt[1], Johanna Emmens[2], Sylvi Irawati[3], Jens H.J. Bos[3], Bob Wilffert[3], Eelko Hak[3] and Rudolf A. de Boer[2]

[1]Utrecht University, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands; [3]University of Groningen, Groningen, Netherlands

Background: Statins prevent cardiovascular events by modifying lipid parameters, including total cholesterol (T-c), low-density lipoprotein cholesterol (LDL-c), high-density lipoprotein cholesterol (HDL-c), and triglycerides (TG). Real-world evidence on a potential statin effect modification by sex is inconclusive, especially for the primary prevention of cardiovascular disease (CVD).

Objectives: To quantify the differences in the effect of statin therapy on lipid parameters between men and women.

Methods: The PharmLines Initiative linked the Lifelines Cohort Study and the IADB.nl prescription database. The linked database covers a representative population from the Netherlands. We selected participants aged >= 40 years at the index date, defined as the date of the first prescription of any statin monotherapy in the study period 2006-2017. Participants' lipid parameters were followed from baseline to the follow-up measurement. Multivariate regression modeling was used to compare the difference of the mean percentage change of lipid parameters (%MD) from baseline to follow-up between the sexes.

Results: Out of 5,366 statin users from approximately 50,000 participants available in the final linked database, 685 were statin initiators. At baseline, women had significantly higher levels of mean T-c, LDL-c, and HDL-c than men (all p-values < 0.01). At follow-up, women had a significantly higher mean percentage change of HDL-c compared to men (adjusted %MD 5.59, 95% CI 2.42-8.75, p < 0.01). There was no significant sex difference in other parameters, nor in the proportion of men and women who achieved LDL-c <=2.5 mmol/L.

Conclusions: Statins appear to have a greater effect on increasing HDL-c levels in women than men while showing similar effect on T-c, LDL-c, and TG levels in both sexes independent of adherence and statin dose or type. Other factors might play a role in opposing statin HDL-c elevating effects in men. Men should not be treated differently than women.

4758 | Real-world short- and long-term effects of antibiotic treatment of acute COPD exacerbations in outpatients: A cohort study under the Pharmlines initiative

Yuanyuan Wang[1], Victor Pera[1], H. Marike Boezen[2], Jan-Willem C. Alffenaar[3], Bob Wilffert[1], Rolf H.H. Groenwold[4] and Eelko Hak[1]

[1]Groningen Research Institute of Pharmacy, University of Groningen, Groningen, Netherlands; [2]University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [3]School of Pharmacy, University of Sydney, Sydney, Australia; [4]Leiden University Medical Center, Leiden, Netherlands

Background: Although antibiotic treatment is recommended for acute exacerbations of COPD (AECOPD) under specific circumstances, the treatment's value in an outpatient setting is unclear.

Objectives: To evaluate the real-world short- and long-term effects of antibiotic treatment on AECOPD outpatients.

Methods: This cohort study was conducted under the PharmLines Initiative that linked the Lifelines database with the prescription database IADB.nl during 2005-2017. We included participants with a first recorded diagnosis of COPD who underwent systemic glucocorticoids treatment for an AECOPD episode. The exposed and reference group was defined as patients who received and not received any antibiotic prescriptions during AECOPD treatment. The short-term outcome was AECOPD treatment failure within 14 -30 days after the index date. The long-term outcome was the time to next exacerbation within one year's follow-up. Binary logistic regression analysis combined with propensity scores (PS) were used to estimate the association between antibiotic use and treatment failure. The risk of another exacerbation was assessed using Kaplan-Meier survival and Cox regression analyses. Several subgroup and sensitivity analyses were also performed.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We analyzed data for 1,105 AECOPD patients. Antibiotics were prescribed for 518 patients (46.9%) while 587 patients (53.1%) received no antibiotics. The overall antibiotic use was associated with a significant relative risk reduction of AECOPD treatment failure by 33%-37% compared with the risk for the reference group (adjusted odds ratio [aOR]: 0.67 [95% CI: 0.42-1.04] and 0.63 [95% CI: 0.40-0.99] by regression and PS analyses, respectively). Similar protective effects were observed for doxycycline, macrolides and co-amoxiclav, but not for amoxicillin, and only the effects of doxycycline were statistically significant (aOR 0.53 [95% CI: 0.28-0.99] by PS analysis). There was no difference between the exposure and reference groups regarding the risk of and time to next exacerbation, irrespective of the follow-up duration.

Conclusions: Our finding that antibiotics treatment supplementing systemic glucocorticoids reduces short-term AECOPD treatment failure in real-world settings concurs with those of clinical trials. Larger studies of high quality are needed to confirm the beneficial effects for specific antibiotics. Our results after controlling for confounding suggest that unmeasured confounding in observational studies may induce underestimated antibiotic beneficial effects on AECOPD.

4996 | Safety and effectiveness of medical cannabis in the real-world: Results of the Quebec cannabis registry

Yola Moride[1,2], Michelle Canac-Marquis[3], Rihab Gamaoun[4], Pierre Beaulieu[5], Andrée Néron[5], Marc O. Martel[3], Jordi Perez[3], Julie Desroches[5], Maja Kalaba[6], Marc Ware[6] and Antonio Vigano[3]

[1]Université de Montréal, Montreal, QC, Canada; [2]Rutgers, The State University of New Jersey, New Brunswick, NJ; [3]McGill University, Montreal, QC, Canada; [4]Research Institute of the McGill University Health Centre, Montreal, QC, Canada; [5]Université de Montréal, Montreal, QC, Canada; [6]Canopy Growth Corporation, Montreal, QC, Canada

Background: Although medical cannabis (MC) has been available in Canada since 1999, the non-recognition of cannabis-based medical products as a drug restricted its medical access. To overcome this situation, the Quebec College of Physicians authorized the use of MC in 2014 only within a research framework.

Objectives: The Quebec Cannabis Registry (QCR) aimed to describe the indications, dosages, safety and effectiveness of medical cannabis products used in the real-world setting.

Methods: All adult (≥18 years) Quebec residents who were authorized to use MC between May 2015 and October 2018 were enrolled. Data were collected at inclusion (demographics, indications, dosage, medical history, concomitant medications) and every three months for 24 months (characteristics of cannabis treatment, clinical outcomes, adverse events (AEs), pain severity and interference (Brief-Pain Inventory), well-being (Revised-Edmonton Symptom Scale-R), quality of life (EQ5D5L).

Results: A total of 2,991 eligible patients were enrolled. Gender distribution was similar and mean age was 50.9 years (SD 15.7 years). The top four indications were chronic pain (62.4%), mood disorders (12.1%), oncology (11.8%), neurological disorders (8.2%). Statistically significant improvements in all outcome domains (i.e., pain severity, pain interference, well-being, quality of life) were observed between baseline and the 3-month follow-up. Results also revealed significant improvements in pain intensity, pain interference, and quality of life between the 3 and 6 months. A total of 110 (3.7%) patients reported AEs: 26 case reports met the criteria of seriousness (Psychiatric disorders [30.8%], Respiratory, thoracic and mediastinal disorders [30.8%], Nervous system disorders [23.1%]), eight of which were likely or probably related to MC. There were two deaths, although unlikely related to MC.

Conclusions: Real-world evidence provided by the QCR in the form of a population-based study supports the safety and effectiveness of MC use for the improvement of pain severity, pain interference, well-being and the quality of life in a variety of medical conditions.

4999 | Effect of adherence to anticoagulation on the incidence of ischemic stroke in the patients with atrial fibrillation: A retrospective cohort study

Won Kyung Lee[1], Young-Jin Ko[2], Sun-Young Jung[3], Seongill Woo[1], Byung-Joo Park[2] and Joongyub Lee[1]

[1]Inha University Hospital, Incheoin, Republic of Korea; [2]Seoul National University, Seoul, Republic of Korea; [3]Chung-Ang University, Seoul, Republic of Korea

Background: Although NOAC had comparable or superior effectiveness compared to VKA in AF, outcomes in low compliance group was limited in the published literature.

Objectives: The purpose of this study is to evaluate the effectiveness and safety of anticoagulation among noncompliant patients using NOAC or VKA compared to those compliant to NOAC treatment.

Methods: This study was performed using the National Health Information Database from 2009 to 2018. A retrospective cohort was constructed with the patients newly diagnosed as non-valvular atrial fibrillation from 2010 to 2018. All participants were required to be between 18 to 100 years old, newly diagnosed AF from 2010.1-2018.6 without AF-related claim in the previous year, and CHA2DS2-VASc score of at least two. Patients with diagnosis codes indicating prosthetic heart valves or valvular heart disease, end stage renal disease, joint replacement surgery, ischemic stroke or major bleeding before enrollment were excluded. The primary exposure is compliance of NOAC (dabigatran, rivaroxaban, apixaban, and edoxaban) or VKA (warfarin) defined based on 80% Proportion of Days Covered (PDC) measured during 180 days after starting OAC. Study subjects were categorized into four treatment groups: VN (VKA non-compliant), VC (VKA compliant), NN (NOAC non-compliant), and NC (NOAC compliant). We followed up patients to the incidence of ischemic stroke, bleeding, switching of drug, death, 910 days after enrollment, or end of study period whichever came first. The differences in the baseline characteristics of a group from NC were calculated as standardized differences before and after the IPT weighting.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The IPT weighted cumulative incidence rate of ischemic stroke was estimated considering bleeding, switching and death as competing events. Subdistributional hazard model was used to calculate the weighted hazard ratio. NNT and NNH for each outcome was presented as the reciprocal for difference of the IPT weighted cumulative incidence.

Results: We identified 84,227 eligible patients who was diagnosed as AF and started to take oral anticoagulants from 2010 to 2018. IPT weighted cumulative incidence of ischemic stroke in VN, NN, and NC was 0.07005, 0.07787, and 0.05579 respectively. Weighted hazard ratios for VN and NN was 1.31 (1.26-1.37) and 1.34 (1.29-1.40). NNH by non-compliance to anticoagulation for ischemic stroke in VN and NN was 44 and 39.

Conclusions: Non-compliant groups are prone to have a higher risk of stroke, regardless of OAC class.

5002 | Comparative safety of epoetin versus darbepoetin in prevention of major adverse cardiovascular events in patients undergoing hemodialysis

Raj Desai, Steven Smith, Rajesh Mohandas and Haesuk Park
University of Florida, Gainesville, FL

Background: Anemia is a common and prognostically-significant complication affecting patients requiring hemodialysis. Erythropoietin-stimulating agents (ESAs), including epoetin (EPO) and darbepoetin (DPO), are used widely and interchangeably for treatment of anemia in these patients. A meta-analysis of randomized trials found no difference in mortality between EPO and DPO but was limited by small sample size (2000 patients in 9 trials), short follow-up (< 1 year), and inadequate power.

Objectives: We sought to compare EPO (alpha or beta) and DPO on risk of major adverse cardiovascular events (MACE), including stroke, acute myocardial infarction (AMI) and all-cause mortality in patients initiating maintenance hemodialysis.

Methods: We conducted a retrospective cohort study using US Renal Data System data, which includes Medicare patients initiating hemodialysis, from 2012 to 2016. Patients were included if they were aged ≥ 18 years, and initiated EPO or DPO. Follow-up started from drug initiation until the first occurrence of: MACE, discontinuation of therapy (i.e., no fill for 30 days), switch to the comparator, initiation of pegylated epoetin, end of hemodialysis, end of Medicare enrollment, or end of study period (31st December 2016). We controlled for confounding using propensity score (PS) 1:3 matching. Cox proportional hazards regression model was used to compare the risk of MACEs between EPO and DPO.

Results: After PS matching, a total of 32,155 patients were included (24,116 EPO users and 8,039 DPO users). MACE incidence was 37.3 and 39.9 per 100 person-years in the EPO and the DPO groups, respectively. In the multivariable model, use of EPO was associated with a 32% lower risk of MACE (adjusted hazard ratio (aHR): 0.68; 95% CI: 0.66, 0.70). EPO users were also at lower risk of AMI (aHR: 0.87; 95% CI: 0.81,0.93), stroke (aHR: 0.85; 95% CI: 0.80, 0.90) and all-cause mortality (aHR: 0.63; 95% CI: 0.61,0.65) compared to DPO users.

Conclusions: Our findings suggest that risk of MACE is very high in Medicare patients with incident ESA use. Furthermore, EPO appears to be superior to DPO in preventing the development of MACE among such patients.

5024 | Newer generation diabetes medications and cardiovascular outcomes among older women with breast cancer and diabetes

Jifang Zhou, Nadia Nabulsi, Alemseged Asfaw, Inyoung Lee, Colin Hubbard and Gregory Calip
University of Illinois at Chicago, Chicago, IL

Background: Sodium-glucose co-transporter 2 (SGLT-2) inhibitors, dipeptidyl peptidase 4 (DPP-4) inhibitors and glucagon-like peptide-1 (GLP-1) receptor agonists are newer generation diabetes drug classes with efficacy demonstrated in reducing HbA1c and conferring cardiovascular benefits, although evidence on these associations is limited among cancer patients with high treatment-related cardiovascular risk.

Objectives: To describe rates of major cardiovascular outcomes among older women with breast cancer and diabetes using SGLT-2 inhibitors, DPP-4 inhibitors and GLP-1 agonists.

Methods: *1. Design, Setting and Participants* We conducted a retrospective cohort study of women with incident stage I-III breast cancer and pre-existing diabetes at the time of diagnosis between 2008 and 2016 using the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked database. Women were required to be continuously enrolled in Medicare Parts A, B and D for at least one year prior to breast cancer diagnosis and followed until the first of disenrollment, death or end of follow up. *2. Exposures* Time-varying use of SGLT-2 inhibitors, DPP-4 inhibitors and GLP-1 agonists. *3. Main outcome measures* Major adverse clinical events (MACE) defined as the composite of death, myocardial infarction, coronary revascularization, stroke, and hospitalization due to heart failure. *4. Statistical analysis* Multivariable Cox proportional hazards models were used to estimate adjusted hazard ratios (HR) and 95% confidence intervals (CI) for risk of MACE.

Results: A total of 13,993 women with breast cancer and diabetes with a mean (SD) age at diagnosis of 74.9 (6.6) years were included in our analyses, among whom newer generation diabetes medication exposure included ever users of SGLT-2 inhibitors (n=300), DPP-4 inhibitors (n=2,476) and GLP-1 agonists (n=444). Over a median duration of 3.1 years follow-up, 3,702 (26.5%) patients experienced MACE with rates of 65.9, 74.5 and 62.6 per 1,000 person-years among SGLT-2 inhibitor, DPP-4 inhibitor and GLP-1 agonist users respectively. In Cox proportional hazards models, the risk of MACE was reduced with use of GLP-1 agonists (HR 0.75; 95% CI, 0.58-0.96), but not SGLT-2 inhibitors (HR 1.22; 95% CI, 0.82-1.83) or DPP-4 inhibitors (HR 1.07; 95% CI, 0.95-1.19).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: We found reduced incidence of major cardiovascular adverse events among breast cancer survivors with diabetes that used GLP-1 agonists. Our study and future research may provide evidence on the safety and cardiovascular benefits of newer type 2 diabetes medications among breast cancer survivors.

5073 | Longitudinal LDL changes among proprotein convertase subtilisin kexin type 9 inhibitor (PCSK9i) users in the United States

Kathleen M. Andersen[1,2], Derek K. Ng[1], Michael J. Blaha[1,3], Jodi B. Segal[1,2,4] and G. Caleb Alexander[1,2,4]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Center for Drug Safety & Effectiveness, Johns Hopkins University, Baltimore, MD; [3]The Ciccarone Center for the Prevention of Cardiovascular Disease, Johns Hopkins School of Medicine, Baltimore, MD; [4]Division of General Internal Medicine, Johns Hopkins School of Medicine, Baltimore, MD

Background: The PCSK9i are associated with ~60% reduction in low density lipoprotein (LDL) cholesterol in clinical trials, compared to maximal statin doses. However, their effect among real-world users is unclear.

Objectives: To characterize LDL changes in response to PCSK9i initiation.

Methods: Data are from individuals with at least 1 dispensation for alirocumab or evolocumab between July 2015 (FDA approval of first PCSK9i) and December 2017 in the IBM MarketScan® Commercial Claims and Encounters Database. Analyses were further restricted to PCSK9i users with LDL results available 3 months prior to initiation, as well as at least one measure in the 12 months after initiation. LDL values more than 3 months after last PCSK9i claim were excluded. Biologically implausible results (<5 or >1,000 mg/dL) were also excluded; to convert to mmol/L, multiply by 0.02586. In cases where multiple lab values within a given period were available, the later LDL value was chosen. We report mean LDL change with standard deviations (SD), percentage of persons <70 mg/dL by 6 months, and pre-post percent change while on PCSK9i therapy.

Results: We identified 378 eligible PCSK9i users, of whom 40% used lipid-lowering therapy in the 6 months prior to PCSK9i initiation (21% maximal statin, 18% non-maximal statin, 1% ezetimibe). The mean LDL 3 months prior to initiation was 140 mg/dL (SD 58). A rapid decrease in LDL after 3 months of PCSK9i treatment was noted (n=259, mean -53 mg/dL change from baseline, SD 51), with no additional decreases after 6 months (n=200, -59 mg/dL (SD 50) from baseline, difference from 3 months p-value=0.23) nor 12 months (n=226, -50 mg/dL (SD 53) from baseline, difference from 6 months p=0.07). By 6 months, 42% were <70mg/dL, a pragmatic goal from pivotal trials now adopted by guidelines. There was substantial variability across individual pre-post change (median -39%, interquartile range -5% to -60%).

Conclusions: While the average LDL reduction in PCSK9i clinical trials was ~60%, only one in four PCSK9i real-world users experienced such magnitude of decrease. The individuals we observed had 20-40 mg/dL higher pre-treatment LDL values than those enrolled in clinical trials for initial FDA approval in 2015, and were well above current indications for PCSK9i treatment in the US. This may reflect worse disease severity, or the fact that only one in five individuals were also using high dose statins as recommended. This work highlights important differences between clinical trial and real-world PCSK9i users, and supports the value of real-world investigations of PCSK9i utilization, safety and effectiveness.

5105 | Comparing cardiovascular benefits of sodium glucose cotransporter-2 inhibitors and glucagon-like peptide-1 receptor agonists in older adults with diabetes

Phyo Htoo[1], John Buse[1], Tiansheng Wang[1], Virginia Pate[1], Matthew Crowley[2] and Til Stürmer[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Duke University, Durham, NC

Background: Antihyperglycemic agents, sodium glucose co-transporter-2 inhibitors (SGLT-2i) and some glucagon-like peptide-1 receptor agonists (GLP-1ra) were found in clinical trials to reduce major cardiovascular disease (CVD) outcomes relative to placebo. But their comparative effects in real world populations with various underlying CVD risks are unknown.

Objectives: To estimate the effects of SGLT-2i vs. GLP-1ra on the risk of congestive heart failure (CHF) hospitalization, stroke, myocardial infarction (MI) and a composite of stroke, MI and all-cause mortality.

Methods: We identified SGLT-2i and GLP-1ra initiators among Medicare fee-for-service enrollees from 2013-16, after a 1-year washout during which there was no SGLT-2i or GLP-1ra prescription. Follow-up for outcomes began on the second prescription date until death or disenrollment (intent-to-treat, ITT) additionally censoring for drug changes in separate as-treated analyses. We used validated claims-based algorithms and diagnoses in inpatient care to define cardiovascular outcomes. Propensity score (PS) weighted Cox models were used to estimate hazard ratios (HR), controlling for demographics, major comorbidities, co-medications, frailty indicators, behavioral and socioeconomic risk factors. We used Fine and Gray Cox model to account for death as competing risk to examine each CVD separately. We conducted analyses with and without excluding major CVD at baseline.

Results: Among 21,596 SGLT-2i and 17,718 GLP-1ra initiators, we identified 824 and 1,149 CHF hospitalizations respectively. After a median 1-year follow-up, ITT HR for the effect of SGLT-2i vs. GLP-1ra on CHF was 0.83 (95% CI: 0.71, 0.96). As-treated HR was 0.70 (95% CI: 0.58, 0.85). After excluding prevalent CHF, HRs were slightly higher: 0.92 (0.69, 1.22) for ITT and 0.70 (0.48, 1.03) for as-treated. Risk of composite outcome was similar: ITT HR of 1.04 (0.93, 1.17) but after excluding prevalent CVD, the risk was slightly higher for SGLT-2i: ITT HR of 1.11 (0.92, 1.33). The MI risk was slightly higher for SGLT-2i: ITT HR of 1.13 (0.91, 1.42) and with no prevalent

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

outcomes, HR was 1.20 (0.86, 1.67). HR for stroke was 1.25 (0.96, 1.64) and with no prevalent events, it was 1.35 (0.92, 1.97). As-treated HRs were similar.

Conclusions: SGLT-2i were found to have lower risk of CHF hospitalization and similar risk of a combined MI, stroke and all-cause mortality outcome, vs. GLP-1ra initiators but a slightly higher risk of each of MI and stroke. This has implications in optimizing cardiovascular outcomes in older diabetes patients.

5109 | Dementia and effectiveness and safety of apixaban versus warfarin and other direct oral anticoagulants in older adults with atrial fibrillation

Kueiyu Joshua Lin[1,2], Sebastian Schneeweiss[1], Ajinkya Pawar[1] and Dae Hyun Kim[1,3]

[1]*Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA;* [2]*Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA;* [3]*Hebrew Rehabilitation Center, Harvard Medical School, Boston, MA*

Background: Apixaban has been considered a preferred choice for stroke prevention in older adults with non-valvular atrial fibrillation (AF). Dementia is prevalent in the elderly and associated with higher risks of complications while taking oral anticoagulants (OAC), but how dementia affects comparative effectiveness and safety of apixaban vs. other OACs is unknown.

Objectives: To determine the comparative safety and effectiveness of apixaban vs. other OACs in patients with dementia and non-valvular AF.

Methods: We used the US Medicare claims data to establish 4 new-initiator cohorts: patients aged ≥ 65 year with a dispensing of warfarin, dabigatran, rivaroxaban, and apixaban, respectively, without any OAC use in the preceding 180 days from 2013/1 to 2017/12 (cohort entry date= first dispensing date). The study cohorts were required to have a diagnosis of dementia and non-valvular AF in the preceding 180 days (baseline assessment period, BAP). Primary outcome was a composite endpoint of death, hospitalization for ischemic stroke or major bleeding and we studied each specific outcome secondarily. We used 1:1 propensity score-matching to adjust for 79 potential confounders assessed in BAP.

Results: Our study cohort included a total of 32,440 warfarin (mean age 81.5 years, female 60.8%), 23,134 rivaroxaban (mean age 81.3 years, female 63.7%), 3,643 dabigatran (mean age 80.8 years, female 57.3%), and 31,218 apixaban (mean age 82.0 years, female 61.6%) initiators with dementia and non-valvular AF. In the warfarin-apixaban cohort (17,187 matched pairs), the rate (per 100 person-years) of the composite endpoint in warfarin-initiators was higher than that of apixaban-initiators (52.8 vs 34.3; adjusted hazard ratio [aHR], 1.4; 95% confidence interval [CI] 1.3-1.5). In the rivaroxaban-apixaban cohort (18,268 pairs), the rate of the composite endpoint in rivaroxaban-initiators was higher than apixaban-initiators (43.9 vs. 31.1; aHR, 1.3; 95% CI, 1.2-1.4). In the dabigatran-apixaban cohort (3,166 pairs), the rate of the composite endpoint in dabigatran-initiators was higher than that of apixaban-initiators (34.1 vs 25.3; aHR, 1.3; 95% CI, 1.1-1.5). The superiority of apixaban was primarily due to higher risks of major bleeding associated with other OACs (aHR [95% CI] comparing warfarin, rivaroxaban, and dabigatran vs. apixaban was 1.7 [1.5, 1.9], 1.6 [1.4-1.8] and 1.3 [1.0-1.7], respectively).

Conclusions: In older adults with dementia and non-valvular AF, apixaban was associated with a favorable benefit-risk profile compared to other OACs for stroke prevention.

5121 | Safety and effectiveness of extended treatment with oral anticoagulants in patients with venous thromboembolism

Ajinkya Pawar, Katsiaryna Bykov, Chandrasekar Gopalakrishnan, Geetha Iyer, Helen Tesfaye, Kristyn Chin and Joshua J. Gagne

Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Background: Guidelines for the treatment of venous thromboembolism (VTE) recommend that patients should be treated for at least 90 days with oral anticoagulants. For patients who require extended treatment, there is limited evidence on which agent provides the best balance of benefits and risks.

Objectives: To compare extended treatment for VTE with apixaban, rivaroxaban, and warfarin with respect to recurrent VTE, major bleeding, and death.

Methods: Using three databases (Optum Clinformatics, 2009-2018; Medicare fee-for-service and IBM MarketScan 2009-2017), we identified adults (≥18 years) who initiated oral anticoagulation following discharge from first VTE hospitalization and compared those who extended treatment with apixaban, rivaroxaban, or warfarin beyond an initial 90-day treatment episode. We adjusted for 74 confounders using propensity score (PS) matching weights. In the primary analysis, patients were followed from the end of the initial 90-day treatment episode until treatment cessation, outcome, death, disenrollment, or end of available data. Outcomes of recurrent VTE and major bleeding were based on hospitalized events using validated algorithms. Weighted Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI). In secondary analyses, we compared extended treatment beyond 180, 270, and 360 days.

Results: We identified 64,487 eligible patients who received extended treatment beyond 90 days (8,769 apixaban, 12,281 rivaroxaban, 43,437 warfarin); 32,380 extended treatment beyond 180 days, 17,739 beyond 270 days, and 5,808 beyond 360 days. Covariates were well-balanced across groups after PS-weighting. We observed 493 recurrent VTE events, 827 major bleeding events, and 1,418 deaths during 17,571 person-years of follow-up in the primary analysis. HRs (95% CIs) comparing extended treatment with apixaban

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

vs. warfarin were 0.75 (0.62-0.91) for recurrent VTE, 0.92 (0.80-1.06) for major bleeding, and 0.79 (0.71-0.88) for death. Corresponding HRs for rivaroxaban vs. warfarin were 0.91 (0.79-1.06), 1.01 (0.89-1.14), and 0.91 (0.83-1.00). Comparative results were consistent when treatment was extended beyond 180, 270, and 360 days.

Conclusions: This study found that extended treatment with apixaban was associated with a lower rate of recurrent VTE and death compared with warfarin in routine clinical care without an increased rate of major bleeding. Smaller differences were observed when comparing rivaroxaban with warfarin for recurrent VTE and death.

5156 | Risk of major adverse cardiac and bleeding events with antiplatelet-apixaban compared to antiplatelet-rivaroxaban in patients with acute coronary syndrome

Ghadeer K. Dawwas[1], Eric Dietrich[2] and James D. Lewis[1]
[1]*University of Pennsylvania, Philadelphia, PA;* [2]*University of Florida, Gainesville, FL*

Background: The beneficial effect of apixaban, a novel direct-acting oral anticoagulant, has been established in patients with atrial fibrillation (AF). However, evidence regarding its effectiveness and safety in combination with antiplatelet in patients with acute coronary syndrome (ACS) remains limited.

Objectives: We aimed to assess the comparative effectiveness and safety of antiplatelet-apixaban compared to antiplatelet-rivaroxaban in patients with AF and ACS.

Methods: We conducted a retrospective cohort analysis using Optum Clinformatics from Jan 1, 2013 to Dec 31, 2018, among patients aged ≥18 years, with a history of AF, and who were hospitalized for ACS (principal discharge diagnosis (ICD-9: 410.xx and 411.xx; ICD-10: I21 and I22)). The AF diagnosis required the presence of one inpatient or two outpatient diagnoses within 1 year. Patients were required to have twelve months of continuous enrollment in medical and pharmacy benefits prior to the index-date, and have used a combination of antiplatelet-apixaban or antiplatelet-rivaroxaban within 30 days of their first ACS diagnosis. The primary effectiveness outcome was the incidence of major adverse cardiac events (MACE) and the primary safety outcome was the incidence of major bleeding events including intracranial hemorrhage, gastrointestinal bleeding and other major bleeding events. We used Cox-proportional hazard models after propensity score matching (PSM) (1:1) to obtain hazard ratio (HR) and 95% confidence interval (CI).

Results: We identified a total 2,586 patients with AF followed by ACS who used a combination of antiplatelet-apixaban or antiplatelet-rivaroxaban. In the PSM cohort, patients' characteristics, including age, sex, and the presence of comorbid conditions were well balanced between the two groups (all standardized differences <0.1). The incidence rate of MACE was 23 and 35 per 100 person-years in the antiplatelet-apixaban and antiplatelet-rivaroxaban groups, respectively. The incidence of major bleeding events per 100 person-years was 7 and 13 in the antiplatelet-apixaban and the antiplatelet-rivaroxaban, respectively. Compared to antiplatelet-rivaroxaban, the use of antiplatelet-apixaban was associated with a lower risk of CVD, HR, 0.73 [0.58- 0.93] and major bleeding events HR, 0.60 [0.37, 0.80].

Conclusions: In this population-based cohort of incident ACS patients, the use of antiplatelet-apixaban was associated with a lower risk of MACE and major bleeding events compared to antiplatelet-rivaroxaban.

5158 | Safety of off-label dose reduction of non-vitamin K oral anticoagulants in patients with atrial fibrillation treated in routine care

Carline van den Dries[1], Rianne van den Ham[2], Patrick Souverein[2], Romin Pjouheshnia[2], Geert-Jan Geersing[1] and Sander van Doorn[1]
[1]*Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands;* [2]*Division of Pharmacoepidemiology and Clinical Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands*

Background: While non-vitamin K antagonist oral anticoagulants (NOACs) are increasingly being prescribed, concerns have emerged about patients receiving a reduced NOAC dose without a clear indication. The clinical impact of such 'off-label' dose reduction is yet unknown.

Objectives: To investigate the safety of off-label NOAC dose reduction compared to on-label standard dosing in AF patients treated in routine care.

Methods: This population based cohort study used data from general practitioner practices contributing to the United Kingdom Clinical Practice Research Datalink. Adult, non-valvular AF patients with a first NOAC prescription between January 1st 2010 and July 1st 2018 were included if they received an on-label standard dose or an off-label reduced dose, based on the summary of product characteristics. The primary outcome was ischaemic stroke. Secondary outcomes were major and non-major bleeding. We performed Cox proportional hazards analyses with inverse probability of treatment weighting (IPTW) on the propensity score to adjust for measured confounding.

Results: 20,688 new NOAC users contributing to 23,665 person years of follow-up were included, of whom 18,194 (88%) patients used an on-label standard dose and 2,494 (12%) patients used an off-label reduced dose. Median age was 72 years (interquartile range (IQR) 66-78) for on-label standard dose users and 79 years (IQR 73-86) for off-label reduced dose users. 152 ischaemic strokes occurred in the on-label standard dose group, vs. 19 ischemic strokes in the off-label reduced dose group (incidence rates 0.70 vs. 0.94 per 100 person years, respectively). The crude hazard ratio (HR) for ischemic stroke was 1.27 (95% confidence interval (CI) 0.79-2.05) for the off-label reduced dose users versus the on-label standard dose users. IPTW using the propensity score resulted in a HR of 1.10 (95% CI 0.88-1.38).

Conclusions: In this study using data from routine practice, 12% of AF patients used an off-label reduced NOAC dose. This did not appear to

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significantly increase the risk of ischaemic stroke in patients with AF, although numbers of events were small. Results on the secondary outcomes will be ready to present at the conference.

Drug Utilization Research -> Changing drug utilization (interventions and implementation research)

68 | Changes in prescribing of sodium-glucose co-transporter 2 inhibitors and dipeptidyl peptidase 4 inhibitors in Singapore

Louise G.H. Goh, Jiandong Sun and Kwong Ng
Agency for Care Effectiveness, Ministry of Health, Singapore, Singapore

Background: The Agency for Care Effectiveness issued subsidy guidance and an Appropriate Care Guide in mid-2017 to encourage use of sodium-glucose co-transporter 2 inhibitors (SGLT2i) over dipeptidyl peptidase 4 inhibitors (DPP4i) as dual or triple therapy based on clinical and cost-effectiveness assessment. It was unclear if these efforts were associated with desired changes in prescribing for managing type 2 diabetes mellitus (T2DM).
Objectives: To assess changes in prescribing of SGLT2i and DPP4i in T2DM patients managed at public healthcare institutions in Singapore post-subsidy.
Methods: A retrospective cohort study was conducted using drug utilisation data and electronic health records. Two random samples (n = 10,000 T2DM patients each) stratified by care setting (i.e. 25% and 75% of patients managed at public hospitals and polyclinics or primary care clinics where most patients and milder cases are managed respectively) were selected from two periods, pre-subsidy (Sep-Dec 2016) and post-subsidy (Sep-Dec 2017). Changes in prescribing rates (PR = number of patients prescribed with studied drug among all T2DM patients in a given period) from pre- to post-subsidy were assessed using logistic regression, adjusted for covariates. Effect size was estimated using odds ratios (ORs) with 95% confidence intervals (CIs).
Results: The two samples were similar in age and gender distribution. Overall, PR of SGLT2i was significantly increased by four times from 1.5% to 6.1% after subsidy listing (OR 3.9, 95%CI 3.2-4.8). The increase was more pronounced when SGLT2i was used with metformin (OR 5.4, 95%CI 4.1-7.2) or insulin (OR 2.7, 95%CI 1.9-3.9) compared with other non-recommended therapies (OR 2.0, 95%CI 1.4-3.1). Metformin monotherapy use also increased significantly by 3.5 times (OR 3.5, 95%CI 3.2-3.9). Conversely, PR of DPP4i was significantly reduced by 50% from 22.4% to 18.3% (OR 0.5, 95%CI 0.5-0.6), particularly for DPP4i monotherapy (OR 0.2, 95%CI 0.2-0.3) or when used with insulin (OR 0.6, 95%CI 0.5-0.7). The increase in overall PR of SGLT2i was primarily driven by increased use in polyclinics (0.01% to 4.8%), despite a significant increase in hospitals (5.9% to 10.0%). The decrease in DPP4i PR occurred only at polyclinics (23.3% to 17.0%, OR 0.4, 95%CI 0.4-0.4) but not at public hospitals (19.7% to 22.0%, OR 1.0, 95%CI 0.9-1.2).
Conclusions: Changes in prescribing suggest early success in driving appropriate use of diabetic drugs, to increase SGLT2i use as second-line dual or triple therapy and reinforce metformin monotherapy use. Differential effect by care setting warrants investigation.

90 | Use of hydrochlorothiazide in Denmark following publication of skin cancer risk findings

Anton Pottegård[1], Bodil H. Bech[2], Sidsel A. Pedersen[1] and Bo Christensen[2]
[1]*University of Southern Denmark, Odense, Denmark;* [2]*Aarhus University, Aarhus, Denmark*

Background: The antihypertensive agent hydrochlorothiazide has recently been linked to an increased the risk of non-melanoma skin cancer, in particular squamous cell carcinoma (SCC). The three key papers were published in rapid succession on June 6th 2017, December 4th 2017, and May 29th 2018, respectively. Based on an evaluation by the Pharmacovigilance Risk Assessment Committee (PRAC) under, Summary of Product Characteristics (SmPC) were updated and 'dear health care professionel' (DHCP) letters were distributed to prescribers across Europe October 17th 2018.
Objectives: In this study, we sought to describe the impact of the dissemination of these findings on the use of hydrochlorothiazide and health care utilization among antihypertensive users in Denmark.
Methods: In this nationwide observational study, we performed descriptive analyses of a cohort comprising all Danish antihypertensive treatment users 2016-2018 (n=1,253,886) with special focus on hydrochlorothiazide users (n=296,597). Data was retrieved from the Danish nationwide health registries, including the Danish National Prescription Registry.
Results: The proportion of antihypertensive fills constituted by hydrochlorothiazide dropped from 12.7% to 9.3% during 2016-2018. This drop was more pronounced among younger patients and patients with a history of skin cancer. Simultaneously, the monthly rate of new hydrochlorothiazide users in Denmark dropped from 2350 to 742. The publication of an increased risk of non-melanoma skin cancer led to an estimated excess of up to 11510 physical and 228700 e-mail/phone consultations to general practitioners. No evidence for increased risk of adverse outcomes was found.
Conclusions: The publication of increased risk of skin cancer with hydrochlorothiazide use have led to a decline in the use of hydrochlorothiazide in Denmark, in particular among younger patients and patients with a skin cancer history.

2347 | Hospitalization for thromboembolic events does not improve adherence to oral anticoagulants in high-risk atrial fibrillation patients

Thanh Phuong Pham Nguyen, Yong Chen, Dylan Thibault, Charles E. Leonard, Sean Hennessy and Allison Willis
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Adherence to oral anticoagulants (OACs) in atrial fibrillation (AF) patients is poor in practice. It is not known whether and how adherence changes after hospitalization for a thromboembolic event (i.e., ischemic stroke (IS) or thromboembolism (TE)), a sentinel health event that may represent an opportunity to enhance medication adherence.

Objectives: The purpose of this study is to examine the impact of hospitalization for an IS/TE on post-discharge adherence to OACs in high-risk AF patients.

Methods: We conducted a quasi-experimental pre-post observational study design using population-based U.S. commercial insurance healthcare claims from the 2009-2016 Optum™ Clinformatics™ Data Mart. Adult AF patients taking OACs with a random hospitalization for a nonbleeding-related reason occurring after the first observed OAC prescription fill, with no other admissions within the preceding and following six months, were identified. Adherence was estimated by the proportion of days covered (PDC) within six months before and after hospitalization. Difference-in-difference (DID) analysis via a generalized linear model was employed to compare pre- and post-hospitalization PDCs by reasons for hospitalization (i.e., IS/TE versus other nonbleeding-related reasons), adjusting for imbalanced baseline characteristics between groups.

Results: We identified 21,400 individuals with AF on OACs who were subsequently hospitalized for a nonbleeding-related reason. Of these, 1,147 (5.4%) were hospitalized for IS/TE, and 20,253 (94.6%) for other reasons. Baseline characteristics were similar between groups. After covariate adjustment, 6-month adherence declined by 1.1% less in individuals hospitalized for IS/TE, compared to other nonbleeding reasons, even though this difference was not statistically significant (p=0.17). Individuals with minority race/ethnicity had a larger reduction by 0.7% in PDC as compared to white patients after discharge (p=0.006).

Conclusions: This real-world study suggests that more effective collaborative strategies across care settings are needed to improve adherence to OACs, particularly after a thromboembolic event and during transition of care.

2364 | Changes in sales of over-the-counter and prescription medicines after rescheduling of codeine to a prescription-only medicine in Australia

Andrea L. Schaffer[1], Rose Cairns[2], Jared A. Brown[1], Natasa Gisev[3], Nicholas A. Buckley[4] and Sallie-Anne Pearson[1]

[1]Centre for Big Data Research in Health, University of New South Wales, Sydney, Australia; [2]School of Pharmacy, University of Sydney, Sydney, Australia; [3]National Drug and Alcohol Research Centre, University of New South Wales, Sydney, Australia; [4]School of Medical Sciences, University of Sydney, Sydney, Australia

Background: Due to concerns over increasing harms, over-the-counter (OTC) codeine-containing products were rescheduled to prescription-only in February 2018 in Australia. This led to a reduction in codeine sales, but it is unknown how the use of other analgesic products changed.

Objectives: We determined the impact of the rescheduling on sales of potential market substitutes for OTC codeine, including OTC and prescription analgesics, products to treat cold and flu symptoms, and cough suppressants.

Methods: We conducted interrupted time series analyses using pharmaceutical sales data to Australian community pharmacies (2015-2019). We quantified changes in monthly tablet sales/10,000 population of: codeine-containing products, OTC analgesics (paracetamol, NSAIDs, and their combinations), prescription analgesics (NSAIDs, tramadol, strong opioids, gabapentinoids, antimigraine medicines), and OTC cold/flu products and cough suppressants containing opioid derivatives (dextromethorphan, pholcodine, dihydrocodeine).

Results: In the year before rescheduling was announced, OTC codeine sales were 248,127 tablets/10,000 population and prescription codeine sales were 106,621 tablets/10,000 population. After rescheduling, we observed a small level shift increase in prescription codeine sales (+2247 tablets/10,000 population, 95%CI 1231-3264) that did not offset the decrease in OTC sales. We observed an increase in sales of all OTC non-codeine-containing analgesics combined (+37,856 tablets/10,000 population, 95%CI 26,143-49,569), with the greatest increases observed for single-ingredient paracetamol (+41,415 tablets/10,000 population, 95%CI 31,374-51,456), ibuprofen (+1392 tablets/10,000 population, 95%CI 916-1868), combination paracetamol/ibuprofen (+1618 tablets/10,000 population, 95%CI 1567-1669) and other paracetamol combinations (+233 tablets/10,000 population, 95%CI 112-353). We did not observe increases in any non-codeine-containing prescription analgesic sales or a meaningful increase in sales of OTC cold/flu products or cough suppressants containing opioid derivatives with the potential for extra-medical use.

Conclusions: The reduction in OTC codeine sales was offset by sales of OTC paracetamol, ibuprofen, and paracetamol combinations rather than prescription analgesics. These products carry no risk of dependence, but excessive or inappropriate use is associated with harms such as liver damage or gastrointestinal bleeding. Further monitoring of adverse events associated with these products is warranted.

2418 | Trends over time in the implementation of opioid risk minimization measures and in opioid-related harms in Canada: A mixed-methods study

Camille Goyer[1], Genaro Castillon[2] and Yola Moride[1,2,3]

[1]Université de Montréal, Montreal, QC, Canada; [2]YOLARX Consultants, Montreal, QC, Canada; [3]Rutgers, The State University of New Jersey, New Brunswick, NJ

Background: Canada is experiencing a major opioid epidemic. Multiple guidance's, policies and risk minimization measures (RMMs) have so far been implemented without an integrated approach, which makes the evaluation of their effectiveness challenging.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To develop a timeline of policies and interventions in Canada over the past five years and assess trends over time in pharmacovigilance metrics, including the reporting of opioid-related harms, including deaths and, social media coverage.

Methods: The study involved four components: 1) Scoping review of opioid RMMs between 1 January 2016 to 15 November 2019 in Canada; 2) Descriptive analysis of opioid-related harms reported to Canada Vigilance, the national post-market spontaneous reporting database; 3) Qualitative review of opioid-related deaths using narratives of Quebec coroner's reports; 4) Social media coverage on opioids and opioid-related harms (Facebook, Twitter and Reddit) using web-scrapping. Time period for the last three components covered 1 January 2009 to 31 August 2019. Trends over time in RMMs implementation was compared to trends over time in the reporting and social media coverage, without implying causality.

Results: There were 414 Canadian RMMs and policies identified over the study period with a 4-fold increase as of 2016. The most common types were harm reduction (32.0%) (e.g., supervised injection site) and opioid awareness/education (20.0%) (e.g., educational webinars). In Canada Vigilance, there were 6,727 opioid-related harms (4,970 patients) with oxycodone being the most common suspected opioid (30.3%). Most cases were reported by consumers (63.8%) and 98.2% were considered serious. The number of reported cases remained constant over the years 2009 and 2018 (range: 53 - 177/year) while it increased dramatically during the fourth quarter of 2018 (n=661). There were 1,320 opioid-related deaths in Quebec; based on the Coroners' reports, 69.8% were caused by opioids other than heroin, methadone and opium. Compared to 2015, the number of posts increased by 35.4% (Reddit), 329.0% (Facebook) and 381.5% (Twitter) in 2016. Trends plateaued for Reddit and Twitter as of 2017 and increased by 92.5% in 2019 for Facebook, compared to 2016.

Conclusions: A large number of RMMs have recently been implemented in Canada. Trends in the reporting of opioid-related harms increased dramatically as of 2018 and opioid-related deaths in Quebec continue to rise. Media coverage and public awareness have dramatically increased since 2016. Further research is needed to identify which RMM has the greatest impact.

2434 | Application of a frailty index threshold to identify older patients at risk of potentially inappropriate prescribing and adverse drug reactions: A prospective observational study

Shane Cullinan[1], Denis O'Mahony[2] and Stephen Byrne[3]
[1]*Royal College of Surgeons in Ireland, Dublin, Ireland;* [2]*Cork University Hospital/University College Cork, Cork, Ireland;* [3]*University College Cork, Cork, Ireland*

Background: Potentially inappropriate prescribing (PIP) and adverse drug reaction rates (ADR) remain high in the older population. Recent discourse in this area has shown that factors such as fear of deprescribing and lack of time mean that prescribers do not routinely assess the appropriateness of prescriptions for older patients. Previous research by our group identified a frailty index (FI) threshold of 0.16, above which patients were twice as likely to experience PIP and ADRs. The hypothesis was that if these patients at increased risk could be highlighted using a simple indicator such as this, it would urge prescribers to review the medications with an aim to deprescribing or amending the prescription accordingly.

Objectives: The aim of this study was to prospectively apply the frailty index threshold to a new cohort to validate the results obtained previously, and also determine if using such an indicator is more predictive of PIP and ADRs than just using the number of medications a patient takes.

Methods: A FI was constructed and applied to comprehensive geriatric assessments for 545 hospital in-patients. Each patient was then assigned a FI score. Patients above and below the threshold of 0.16 were identified and the relationship between their frailty status and instances of PIP and ADRs was quantified (chi-square test and odds ratios). This was compared to simply using the number of medications as an indicator for predicting PIP/ADRs.

Results: Patients above the FI threshold were significantly more likely to experience an ADR (OR=2.86, p=0.001), and while they were also more likely to experience PIP, this was not significant (OR=1.755, p=0.185). Patients taking 6 or more medications were more likely to experience an ADR, although not significantly (OR=1.27, p=0.189), but *were* significantly more likely to experience PIP (OR=2.45, p<0.0001).

Conclusions: PIP was found to be highly dependent on the number of medications a patient takes. ADRs were found to be more dependent on frailty status. Our previous work found that PIP was highly dependent on *both* frailty and number of medications whereas, similar to this study, ADR occurrence was just found to be related to frailty. Therefore the use of both a FI as well as 'number of medications' seems the best approach to identify patients at risk. These indicators could potentially be implemented in practice by simple 'tick boxes' on a patients chart alerting prescribers to their heightened risk of adverse events.

3715 | Changes in utilization of antihypertensive drugs following angiotensin receptor blocker product recalls in Germany

Salka Enners[1], Marita Kieble[1], Ulrike Rudolph[2], Felix Mahfoud[3], Michael Böhm[3], Ulrich Laufs[2] and Martin Schulz[1,4,5]
[1]*German Institute for Drug Use Evaluation, Berlin, Germany;* [2]*University Hospital Leipzig, Leipzig, Germany;* [3]*Saarland University Medical Center, Homburg, Germany;* [4]*Drug Commission of German Pharmacists (AMK), Berlin, Germany;* [5]*Institute of Pharmacy, Freie Universität Berlin, Berlin, Germany*

Background: Angiotensin receptor blockers (ARBs) are one of the most common drug classes, used by approximately 8 million patients in Germany. Discovery of unacceptable amounts of potentially carcinogenic nitrosamines resulted in more than 30 recalls of generic ARBs, primarily valsartan, between July 4 and December 20, 2018, and in subsequent drug shortages.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: We explored the potential impact of the recalls on the dispensings of valsartan, all ARBs, and other antihypertensives (AHTs).
Methods: We performed a descriptive drug utilization study using the DAPI database of anonymized dispensing data from >80% of community pharmacies at the expense of the statutory health insurance (SHI) funds. Nearly 88% of Germany's population is insured by the SHI system. We included all oral mono and fixed-dose combination products of ARBs, ACE inhibitors (ACEi), calcium channel blockers, and beta-blockers. For the analysis of ARBs individually, we only included mono preparations and combinations with hydrochlorothiazide (HCTZ) because only those were affected by the recalls. We calculated utilization as defined daily doses per 1,000 inhabitants per day (DID). Time trends were analyzed on a quarterly level.
Results: The market shares for valsartan and valsartan/HCTZ drug products recalled in July and November 2018 were both 45% of all valsartan and valsartan/HCTZ-containing drugs. Valsartan dispensings decreased substantially and continuously after first recalls in July 2018 (2Q18: 41.1 DID, 2Q19: 14.0 DID). A simultaneous increase of other ARBs, primarily candesartan was observed. Other ARBs: 2Q18: 77.8 DID, 2Q19: 116.0 DID, of which candesartan was: *2Q18: 57.7 DID, 2Q19: 93.4 DID*. Effects on utilization of ACEi and AHTs overall were not observed. ACEi: 2Q18: 212.3 DID, 2Q19: 209.7 DID; AHTs: 2Q18: 520.9 DID, 2Q19: 529.5 DID. Similarly, there was no impact on the moderate, but continuous increase of the total volume of ARB dispensings (2Q18: 129.4 DID, 2Q19: 141.1 DID).
Conclusions: We noted a substantial decrease in utilization of valsartan but not losartan, irbesartan, olmesartan, or telmisartan after generic ARB product recalls. The total volume of ARB further increased and AHT utilization overall remained nearly unchanged suggesting shifts within the class of ARBs, mostly to candesartan.

3762 | Use of tramadol and other opioids following media attention and risk minimization measures from regulators: A Danish nationwide drug utilization study

Anne Mette S. Sørensen[1], Lotte Rasmussen[2], Martin T. Ernst[2], Stine H. Mogensen[3], Mona V. Laursen[3], Espen Jimenez Solem[1] and Anton Pottegård[2]
[1]*Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark;* [2]*University of Southern Denmark, Odense, Denmark;* [3]*Danish Medicines Agency, Copenhagen, Denmark*

Background: Use of tramadol, including its potential for abuse, has been heavily discussed in recent years. In Denmark, use of tramadol received considerable attention from lay media in June and December 2017. Further, several regulatory actions were taken in September 2017 and January 2017 to restrict the use of tramadol and other opioids.
Objectives: To describe the use of tramadol and other opioids in Denmark following lay media attention in June and December 2017 and regulatory actions in September 2017 and January 2018.
Methods: Using the Danish nationwide health registries, we described the use of tramadol and other opioids in the adult Danish population during 2014 to mid-2019.
Results: From early 2017 until mid-2019, total tramadol use decreased markedly (37%) while total use of morphine and oxycodone use decreased slightly. The quarterly prevalence of tramadol use decreased from 32/1,000 individuals in 2014 to 19/1,000 mid-2019, dropping mainly at the time of media attention. Concomitantly, the prevalence increased for oxycodone (from 5.1 to 7.7) and morphine (from 8.5 to 9.5), mainly due to more short-term and sporadic users, and decreased for codeine (from 14 to 9.4). From 2014 to mid-2017, the incidence of tramadol use was stable (around 2.2/1,000 person-months) but dropped in June 2017 to 1.7/1,000, coinciding with the media attention, and continued to decrease thereafter (to 1.1/1,000 in mid-2019). Tramadol was primarily initiated by GPs (64% in 2018) and hospital prescribers (27%), while treatment was mainly maintained by GPs (93%).
Conclusions: We identified a decline in the use of tramadol coinciding in time with the media attention in 2017 which continued during the regulatory actions taken in 2017-2018. During the same period, the use of other opioids also decreased slightly and generally, there was no evidence of unintended effects on the utilization of opioids related to the media attention and regulatory actions.

3825 | Utilization of sacubitril/valsartan in real-world settings

Efe Eworuke[1], Talia Menzin[2], Joy Kolonoski[2] and Ting-Ying Huang[2]
[1]*US Food and Drug Administration, Silver Spring, MD;* [2]*Harvard Pilgrim Health Care Institute, Boston, MA*

Background: Sacubitril/Valsartan (SV) is first-in-class angiotensin-neprilysin-receptor-inhibitor (ARNI) and angiotensin-receptor-blocker (ARB) approved for the treatment of patients with Heart Failure with Reduced Ejection Fraction (HFrEF). In 2016, the American College of Cardiology (ACC) recommended replacing of angiotensin-converting-enzyme inhibitors (ACEI) or ARB by an ARNI for chronic symptomatic HFrEF to further reduce morbidity or mortality. Real-world utilization of SV is unknown.
Objectives: To evaluate SV use among patients with heart failure (HF) and describe patient characteristics.
Methods: We conducted a retrospective cohort study including HF patients 18 years and older between January 2015 and July 2019 in the Sentinel Distributed Database. We identified new users of ACEI, ARB and the following SV cohorts: new SV users with ACEI (ACEI-SV new users) or ARB (ARB-SV new users) use in the 183 days prior (baseline); SV users who switched from new use ACEI (new-ACEI-SV switchers) or ARBs (new-ARB-SV switchers); and new users of SV without ACEI or ARB in the baseline (new SV users). We followed patients from the SV dispensing (index) date to the earliest of switching to ACEI or ARB, end of treatment episode, disenrollment, death or end of available data, whichever came first. For each cohort,

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

we obtained the number of users each month, time to switch, and patient characteristics before and on the index date.

Results: We identified 703,848 and 318,588 new ACEI and ARB users, compared to 58,141 and 41,351 ACEI- and ARB-SV new users; 6,622 and 3,361 new-ACEI- and new-ARB-SV switchers; and 30,557 and 30,547 new SV users without same-day ACEI and ARB dispensing respectively. Over time, the use of SV increased in all cohorts, with the ACEI-SV new user cohort consistently being the largest. Baseline characteristics were comparable across all SV cohorts. The proportion of SV users who switched to ACEI or ARB was generally low but switching to ARB was more frequent (5.7%). The shortest time to switch (median [Q1-Q3]: 42 [20-99] days) was observed among new SV users who switched to ACEI. The longest time to switch (75 [39-169]) was observed among new-ACEI-SV switchers who switched back to ACEI.

Conclusions: The use of SV for HF remains low with no impact from the recent recommendation by ACC. Barriers to utilization of SV need to be further assessed.

4031 | Utilization and evaluation of chemotherapeutic agents in management of carcinoma breast

U.R. Rakshith[1] and M.S. Vishveswara[2]

[1]JSS College of Pharmacy, JSS AHER, Mysuru, India; [2]Bharath Hospital and Institute of Oncology, Mysuru, India

Background: Breast cancer are the cancer which arising from breast tissue. The incidence of cancer in India is 70-90 cases per 100,000 populations and cancer prevalence is established to be around 2,500,000 (2.5 million) with over 800,000 in India breast cancer has been associated with greater urbanization and changing lifestyles. A drug utilization evaluation study can help us in understanding the prescribing patterns of a drug and possibly the factors influencing the prescribing. Implementation of DUE helps to improve the quality and cost-effectiveness of the drug use thereby improving the patient care.

Objectives: The study was undertaken with aim to assess the prescribing pattern in treatment of breast cancer, to determine the rational use of drug according to the type and grade of breast cancer.

Methods: The prospective observational study was carried out for a period of 6 months in Bharath hospital and institute of oncology Mysuru. The study included all the participants who are receiving adjuvant and neoadjuvant chemotherapy in wards as well as in day care center for carcinoma of breast. All the data were collected from patient case records, laboratory data, Patient or patient's caretaker(s) interview, Treatment chart, by Interviewing healthcare professionals. assessment of utilization of chemotherapeutic agents were carried in hospital. Descriptive statistics were applied to establish the findings.

Results: A total of 100 patients who were receiving anti-cancer agents as either adjuvant or neoadjuvant therapy for breast cancer. Breast cancer were found to be more common among age groups of 50-59 (n=55%), followed by 36-49 years(n=27%), ≤ 35 years (n=13%), ≥70 years (n=5%). Out of 100 study participants 49 women were in premenopausal, 51 individuals were postmenopausal. Majority of participants (34%) were prescribed with AC regimen followed by FAC (17%), FEC (11%). The single drug treatment (2%) was given only for the palliative purpose. 91.17% of individuals who received AC regimen were found be appropriate and 8.82% individuals were found to be in appropriate. In AC Paclitaxel regimen 100% appropriateness was able to find out according to the patient condition. 94.44% FAC regimen was found to be appropriate and 5.55% were found to be inappropriate.

Conclusions: The selection of chemotherapeutic agents was found in compliant with NCCN guidelines. Uses of antiemetic drugs need further improvement in terms of frequency and choice of drug in many cases. Education and training program to nursing staff would certainly help to improvise the delivery of chemotherapy.

4084 | A mixed methods analysis of the use of the systematic tool to reduce inappropriate prescribing in Swiss primary care practices

Katharina T. Jungo[1], Fabian Schalbetter[1], Michael J. Deml[2,3] and Sven Streit[1]

[1]Institute of Primary Health Care (BIHAM), University of Bern, Bern, Switzerland; [2]Swiss Tropical and Public Health Institute, Basel, Switzerland; [3]University of Basel, Basel, Switzerland

Background: With an increasing number of older multimorbid adults (ages >65) with potentially inappropriate polypharmacy, evidence-based clinical decision support systems (CDSS), such as the 'Systematic Tool to Reduce Inappropriate Prescribing' (STRIP) assistant, are promising tools for assisting medication reviews. Little is known about how general practitioners (GPs) perceive the use of CDSS.

Objectives: To explore the use of the STRIP assistant by GPs during a randomized controlled trial.

Methods: We utilized an explanatory mixed methods design, meaning that we first collected quantitative data, which we sought to subsequently better understand through qualitative methods. First, quantitative data about the acceptance and implementation of 'Screening Tool of Older Person's Prescriptions' (STOPP) and 'Screening Tool to Alert doctors to Right Treatment' (START) recommendations, generated by the STRIP assistant, were collected from GPs (N=19) about their patients (n=149). The mean number of recommendations generated, the proportions of different recommendation types, and the proportions of recommendations accepted and implemented by GPs were calculated. Then, semi-structured qualitative interviews (n=9) were conducted with GPs, with the interview guide having been informed by preliminary quantitative data. A framework method analysis will be conducted upon qualitative data collection completion. The combined analyses of both quantitative and qualitative data will allow for better data triangulation.

Results: The mean number of STOPP, START, dosage recommendations and drug-drug interaction alerts generated by the STRIP assistant per study participant was 1.4, 2.3, 0.2, and 1.8 respectively. 40%

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were START recommendations, 25% were STOPP recommendations, 3% were to adapt the dosage, and the rest highlighted drug-drug interactions. GPs reported to discuss 16% of all recommendations generated with patients in a shared decision-making process. 42% of the latter were reported to be implemented. Preliminary qualitative results demonstrate that there are technical problems related to the STRIP assistant's usability, GPs had high expectations about the tool's functionalities, and they had difficulties implementing recommendations together with patients.

Conclusions: Findings indicate that the use of the STRIP assistant by GPs is affected by several limiting factors. GPs only discussed and implemented a small number of recommendations with patients. The qualitative findings help explain the low acceptance and implementation rate of recommendations.

4126 | When less is better: Increase in paracetamol use and poisonings in Switzerland following the introduction of 1,000mg oral tablets

Adrian Martinez-De la Torre[1], Stefan Weiler[1,2], Dominic Stefan Bräm[1], Hugo Kupferschmidt[2] and Andrea M. Burden[1]
[1]*ETH Zurich, Zurich, Switzerland;* [2]*National Poisons Information Centre, Tox Info Suisse, Zurich, Switzerland*

Background: Paracetamol (acetaminophen) is one of the most used pain medications worldwide. While safe within the therapeutic range (<4,000mg daily), intake exceeding daily dose thresholds can lead to hepatotoxicity. In October 2003, 1,000mg oral tablet paracetamol was approved for use in Switzerland. Prior to this, only the 500mg oral tablets were available.

Objectives: To evaluate the impact of the introduction of 1,000mg paracetamol tablets to the Swiss market on utilization and potential poisonings.

Methods: National community pharmacy sales data of oral paracetamol tablets were obtained between 2000 and 2018. Using data from the National Swiss Poisons Centre (Tox Info Suisse), all calls related to poisonings with oral paracetamol tablets between 2000 and 2018 were identified. The total pills sold were tabulated and plotted by calendar year and quarter, and stratified by formulation (500mg vs 1,000mg). The poisonings data were stratified by circumstance of poisoning (accidental vs intentional). An interrupted time series (ITS) analysis examined the impact of introducing 1,000mg, with quarter four (Q4) of 2003 identified as the intervention date. Patient characteristics at the time of reported poisoning were summarised, stratified by pre- and post-intervention periods. Ibuprofen related poisonings were used as a comparator.

Results: There was a rapid uptake in the sales of 1,000mg paracetamol from the introduction in Q4 of 2003, while sales of 500mg steadily decreased. National sales of paracetamol tablets plateaued in 2012, after which an average of 920,000 tablets of 500mg and 6.9 million 1,000mg tablets were sold monthly. From the Tox Info Suisse, we identified 15,790 paracetamol related calls between 2000 and 2018. The ITS analysis identified a significant increase in the number of reported poisonings for paracetamol tablets after the introduction of the 1,000mg dosage form, particularly for accidental circumstances. The proportion of accidental poisonings increased significantly from 20% to 31%. Similarly, the mean dose increased from 6,900mg to 9,000mg. While ibuprofen poisonings increased during the observation period, the significant change point was Q3 2012.

Conclusions: The introduction of 1,000mg paracetamol tablets to the Swiss market in 2003 resulted in an immediate increase in the sales and reports on poisonings with paracetamol in Switzerland. As there is lacking evidence of the clinical effectiveness of paracetamol (500mg or 1,000mg) on pain management, the availability of 1,000mg should be re-evaluated to minimise the risk of accidental poisonings.

4258 | The impacts of publishing evidence on the utilization of oseltamivir and peramivir at an emergency department in South Taiwan

Chen-En Liu[1] and Teng-Chou Chen[2]
[1]*Department of Pharmacy, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan;* [2]*Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom*

Background: About 10% of the emergency department (ED) visits in Taiwan were related to respiratory diseases including influenza in 2018. In addition to taking oral oseltamivir for 5 days, a systematic review (SR) published in July 2017 suggested that the time to alleviation of influenza symptoms or fever was shorter in patients receiving single-dose intravenous peramivir for influenza. However, the influence of the SR on the utilization of these two medicines was still unclear.

Objectives: This study aimed to explore the impacts of the published SR on the utilization of oseltamivir and peramivir at an ED.

Methods: This retrospective cross-sectional study used aggregate-level dispensing data extracted from the hospital information system in a medical center in southern Taiwan from January 2017 to December 2019. Patients who were prescribed oseltamivir and peramivir for influenza at ED were included and the prescriptions of these two medicines were extracted. Monthly utilization of oseltamivir and peramivir was quantified by the number of total defined daily doses (DDDs). An interrupted time-series analysis was performed to evaluate the impacts of the SR on the monthly utilization of oseltamivir and peramivir in July 2017. As influenza has seasonal pattern, an additional time point (December 2017) was tested in the sensitivity analysis to identify potential delay of the effects from July 2017.

Results: Before July 2017, the monthly utilization of oseltamivir increased by 70.8 DDDs (p=0.026) per month. After publishing the SR, the level (β_2: -214.0, p=0.047) and the trend (β_3: -70.9, p=0.027) of monthly utilization of oseltamivir decreased significantly. However,

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

there was no significant change in the level and the trend of monthly utilization of peramivir after July 2017, and the baseline trend of monthly utilization of peramivir keep increasing (β_1: 2.3, p<0.001) from the introducing of peramivir in the medical center in January 2017. The utilization of both oseltamivir and peramivir were not change significantly in December 2017, and this implied that there is no delay effect.

Conclusions: The utilization of oseltamivir decreased after publishing the SR, and peramivir remained its increasing trend from its introducing in January 2017. Further studies need to apply individual patient data to evaluate the appropriateness of prescribing peramivir by identifying patients' characteristics and treatment outcomes.

4309 | Effectiveness of a targeted and tailored pharmacist-led intervention to improve adherence to antihypertensive drugs among patients with type 2 diabetes in Indonesia: A cluster randomized controlled trial

Sofa Dewi Alfian[1,2], Petra Denig[3,4], Rizky Abdulah[5], Hadyana Sukandar[6], Job F.M. van Boven[3,4] and Eelko Hak[1,4]

[1]University of Groningen, Groningen, Netherlands; [2]Universitas Padjadjaran, Jatinangor, Indonesia; [3]University of Groningen, University Medical Centre Groningen, Groningen, Netherlands; [4]Medication Adherence Expertise Centre Of the Northern Netherlands (MAECON), Groningen, Netherlands; [5]Universitas Padjadjaran, Jatinangor, Indonesia; [6]Universitas Padjadjaran, Bandung, Indonesia

Background: Current intervention programs to improve drug adherence are either too complex or expensive for implementation and scale-up in low-middle income countries.

Objectives: To assess the effects of implementing a low-cost, targeted and tailored pharmacist intervention among patients with type 2 diabetes who are non-adherent to antihypertensive drugs in a real-world primary care Indonesian setting.

Methods: A cluster randomized controlled trial with 3-month follow-up was conducted in 10 community health centers (CHCs) in Indonesia among type 2 diabetes patients aged 18 years and older who reported non-adherence to antihypertensive drugs according to the Medication Adherence Report Scale (MARS). Patients in CHCs randomized to the intervention group received a tailored intervention based on their personal adherence barriers at baseline and at 1-month follow-up. Interventions might include reminders, habit-based strategies, family support, counseling to educate and motivate patients, and strategies to address other drug-related problems. Patients in CHCs randomized to the control group received usual care based on the Indonesian guideline. Primary outcome was the between-group difference in medication adherence change from baseline to 3-month follow-up. Secondary outcomes included changes in patients' blood pressure and their medication beliefs.

Results: In total, 201 patients were screened for eligibility to participate. Of them, 113 patients (56 in control group and 57 in intervention group) met the inclusion criteria. Compared with usual care, the intervention significantly improved patient's self-reported adherence (mean difference 2.78 [95%CI: 1.65; 3.91, p-value = <0.001]) at 3-month follow-up. No significant differences in blood pressure level and concern beliefs were found within and between intervention and control groups. Perceived necessity for using antihypertensive drugs increased significantly over time among patients in the intervention group (p-value = 0.024).

Conclusions: A targeted and tailored pharmacist-led intervention resulted in a statistically significant increase in medication adherence and perceived necessity but no significant differences were found in blood pressure level between groups. Future study is needed on identifying which groups derive the most clinical benefit from adherence improvement.

4383 | Protocol for a cluster randomized tailored educational intervention to reduce potentially inappropriate medication among older adults at community healthcare institutions in Beijing

Mengyuan Fu[1,2], Xiaodong Guan[1,2,3] and Luwen Shi[1,3]

[1]School of Pharmaceutical Sciences, Peking University, Beijing, China; [2]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [3]International Research Center for Medicinal Administration, Peking University, Beijing, China

Background: Potentially inappropriate medications (PIMs) are prominent prescribing issues in elderly patients worldwide. Evidence suggests that adequate interventions of PIMs can affect behaviors of healthcare providers, and improve appropriate drug use. However, no study has involved interventions to reduce the PIMs among elderly patients in China.

Objectives: To evaluate the effectiveness of tailored educational intervention, carried out towards general practitioners (GPs) in Chinese primary healthcare institutions, aiming at reducing the occurrence of PIMs in elderly patients.

Methods: 20 primary healthcare stations (CHSs) in Dongcheng district in Beijing will be recruited to a cluster randomized controlled trial. CHSs will be randomized to intervention or control arm with allocation ratio of 1:1. A multifaceted intervention has been tailored towards GPs in intervention arm, where key components are 2-day general training of PIMs guidelines, distributing printed drug handbook including risk and alternative therapeutic options for each drug, and sending individual feedback reports of baseline practice to each participating GP. The control arm will continue their current procedures during the study period. Prescription data for eligible elderly patients (age≥60) from both arm, 3-month prior and after the initiation of the trial, will be derived from Dongcheng Health Service System. *Criteria of PIM for Older Adults in China* will be used as both an educational tool and a quality measure. The primary outcome is the change in proportions of elderly patients exposed to at least one PIM following the intervention. The trial has received ethic approval from Peking University Institution Review Board.

4513 | Effect of bariatric surgery on opioid uses for osteoarthritis in the United States, 2010-2017

Enoch J. Abbey[1], Richard Nudotor[1], Joseph Canner[2], Jennifer Mammen[2] and Kimberley Steele[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Johns Hopkins Hospital, Baltimore, MD*

Background: Obesity is a well-known risk factor for osteoarthritis (OA) which in turn may be treated with prescription opioids. We quantified changes in such use among individuals with OA undergoing bariatric surgery.

Objectives: We aimed to determine the effect of bariatric surgery on opioid prescription use among patients with osteoarthritis.

Methods: We performed a retrospective cohort study of individuals captured within the IBM MarketScan commercial claims database, from 2010 to 2017. To do so, we first derived a cohort of individuals undergoing bariatric surgery and a diagnosis of OA using ICD-9, ICD-10 & CPT codes at baseline. Individuals had at least a 6-month history of opioid-use prior to surgery. Remission of opioid use was defined as no refill of opioids 90 days after a patients' medication was expected to run out post-operatively and relapse as medication refill after at least 90 days of remission. Cox proportional hazards regression to estimate crude and adjusted hazard rations were used.

Results: Of 718 patients with a diagnosis of OA undergoing bariatric surgery between 2010 and 2017, 523(72.8%) experienced remission of opioid-use after surgery. A total of 262 (50%) later experienced relapse and were placed back on opioids, likely for osteoarthritis. Roux-en-Y Gastric Bypass was associated with a lower risk of remission (HR= 0.80 [95% CI; 0.66, 0.96]) and a higher rate of relapse (HR= 1.22 [95% CI; 0.94, 1.6]) compared to Sleeve Gastrectomy. A greater exposure to opioids at the time of surgery and a higher BMI were associated with a lower rate of remission and a higher rate of relapse of opioid use after bariatric surgery.

Conclusions: Bariatric surgery appears to reduce opioid use in patients with osteoarthritis by reducing chronic opioid use and therefore the risk of addictions. A higher exposure of opioids at time of surgery and a higher preoperative BMI are important predictors of remission of opioid use after weight loss surgery, and may correspond to existing dependence and limited improvement in OA respectively.

4568 | Antihypertensive treatment patterns in the United Kingdom

Tianze Jiao[1], Kristian B. Filion[1,2], Antonios Douros[1,2] and Robert W. Platt[1]

[1]*Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, QC, Canada;* [2]*Department of Medicine, McGill University, Montreal, QC, Canada*

Background: Several drug classes are marketed for treating hypertension, and international treatment guidelines are inconsistent in recommendations. As a result, there is a need to better understand how antihypertensive drugs are used in clinical practice.

Objectives: To describe antihypertensive treatment patterns in the UK, which include treatment pathway and length of utilization on each combination, among newly treated hypertensive patients by emulating a target trial.

Methods: The data source for our study was the Clinical Practice Research Datalink, a population-based clinical database that contains electronic clinical records for > 16 million patients seen at > 700 general practitioner practices in the UK. We created a base-cohort of patients with hypertension, defined by a new diagnostic code or elevated blood pressure readings. We included patients initiating an antihypertensive drug between January 1998 and June 2018, with cohort entry defined by the date of this prescription. We applied the same inclusion criteria as the SPRINT trial, a blood pressure management trial, but included patients regardless of their estimated cardiovascular (CVD) risk or diabetes status. Visualization techniques and descriptive statistics were applied to present the treatment pattern, demographic and clinical characteristics.

Results: Our cohort included 660,545 patients. The mean age was 59.7 (standard deviation [SD]: 13.5) years, and 49.0% were men. Patients at low, medium, and high CVD risk were 29.8%, 30.6% and 39.6% of the population. On average, patients received 1.04 (SD: 0.24) antihypertensive drugs at baseline. Overall, 29.0.%, 22.1%, and 21.0% of patients received angiotensin-converting enzyme inhibitors (ACEI), thiazide diuretics (TD), and calcium channel blocker (CCB) as monotherapy at baseline, with subsequent treatment changes occurring after a median of 299, 112, and 182 days. Compared to 2001, patients were more likely to receive an ACEI (16.5% vs. 38.0%) or a CCB (9.4% vs. 36.2%) in 2011. Women were more likely to receive a TD (27.0% vs. 17.0%) as first line therapy than men. Black patients were twice as likely to receive CCB as the first line therapy as Caucasians. Compared to patients at low CVD risk, high-risk patients were less likely to receive an ACEI (33.5% vs. 24.4%) but more likely to receive a CCB (14.4% vs. 25.3%). Over time, fewer different treatment combinations were prescribed, with beta-blockers rarely prescribed with TD.

Conclusions: Several factors were associated with variation of treatment patterns for hypertension. Further analyses assessing clinical outcomes associated with varied treatment patterns are urgently needed.

4585 | Drug utilization evaluation of chemotherapy drugs in various cancers in India

Niharika Jupaka

Talla Padmavathi College of Pharmacy, Warangal, India

Background: Cancers have emerged as a leading cause of mortality in recent years. Though a diverse option of chemotherapeutics is available, rational use is key to success in cancer therapeutics. Evaluating the prescribing patterns of chemotherapy drugs for ensuring effectiveness and patient's quality of life.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To describe chemotherapy regimen utilization, effectiveness and evaluate use against national treatment guidelines.

Methods: A prospective observational study was conducted in department of medical oncology in tertiary care hospitals for a period of three months. Patients with various types of cancers and who were willing to fill informed consent form were included for study. The data were collected in a suitably designed data collection form. Most of the drugs prescribed from the Government of India's National List of Essential Medicines (NLEM).

Results: Among150 patients, the most were female (56%) and most commonly in the 61-75 year old age group (32%). The prevalence of cancers and the most frequently prescribed regimens in these cancers were the following: -lung cancer 22% - paclitaxel and carboplatin (51%).-breast cancer 14% - doxorubicin and cyclophosphamide (40%).-ovarian cancer 9.3% - paclitaxel and carboplatin (73%). -stomach cancer8% - oxaliplatin (60%). The only supportive care medication prescribed for every patient was dexamethasone, and the most commonly prescribed anti-emetic drugs were aprepitant(94%) and palanosetron (97%). Use of chemotherapy drugs in this hospital was found to follow National Comprehensive Cancer Network (NCCN) guidelines.

Conclusions: The utilization of anti-cancer drugs in these hospitals was found to be rational and more than 70% of drugs were prescribed from the NLEM. Assessment of pattern of prescribing should be conducted periodically to minimize the untoward effects of cancer treatments as far as possible.

4661 | Deprescribing in older people: Pharmacoepidemiological tools and measures

Katja Taxis[1], Carina Lundby[2], Lisa Pont[3], Wade Thompson[2], Petra Denig[4] and Anton Pottegård[2]

[1]University of Groningen, Groningen, Netherlands; [2]University of Southern Denmark, Odense, Denmark; [3]University of Technology Sydney, Sydney, Australia; [4]University Medical Center Groningen, Groningen, Netherlands

Background: In an ageing society with a high prevalence of people with multimorbidity and polypharmacy, deprescribing is an emerging concept. Deprescribing can be defined as the planned dose reduction or stopping of medication to improve health-related outcomes or reduce the risk of adverse events. Pharmacoepidemiological tools and measures are needed to support and evaluate the implementation of deprescribing.

Objectives: This symposium will provide an overview of concepts, methods and tools for identifying patients in need of deprescribing as well as for assessing determinants and outcomes of implementing deprescribing. The symposium is intended for researchers, clinicians, and policy makers with an interest in drug utilization research and medicine use in complex populations.

Description: In this symposium we will focus on innovative tools and outcome measures needed to support and evaluate deprescribing in various clinical settings. Anton Pottegård will provide an introduction to the concept of deprescribing, highlight challenges ahead and specific areas where pharmacoepidemiology might contribute with important insights. Petra Denig and Wade Thompson will give an overview of screening tools to ascertain the need for deprescribing. This includes the development of an algorithm with artificial intelligence modeling to identify patients in need of deprescribing. Katja Taxis will discuss the value of various outcome measures to evaluate deprescribing interventions, making use of existing databases. This will include how to measure drug burden in patients with multimorbidity. Carina Lundby will discuss how drug utilization studies can be used in deprescribing research. A recent study exploring medication use among Danish nursing home residents will be used as an example of this and include considerations on how findings can be applied in similar populations across countries. It will further include highlighting of potential reasons for trends in medication use as well as considerations on how to facilitate more appropriate medication use in vulnerable populations like the nursing home population. Lisa Pont will present a case study that illustrates several aspects highlighted in the other lectures. The symposium will conclude with an open panel discussion led by questions from participants.

4768 | Implementing the HOUVAST 2.0 intervention in the Dutch primary care, lessons learned from a process evaluation

Stijn Hogervorst

Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Background: Despite the existence of many effective adherence interventions, they are rarely used in routine care. This gap between research and practice calls for more emphasis on the implementation of adherence interventions.

Objectives: This pilot project aims to implement an existing adherence intervention (HOUVAST 2.0) in the Dutch primary care.

Methods: A qualitative process evaluation was conducted as part of a medication adherence pilot project (HOUVAST 2.0). Data were collected through a focus group and four interviews with ten allied GP and pharmacy staff members. Interviews and focus groups were semi-structured using topic lists based on the RE-AIM implementation framework. Interviews were audiotaped and transcribed verbatim. Atlas.ti 8.0 software was used for coding and structuring of themes. A thematic analysis of the data was performed.

Results: Main themes that emerged were 'Training and preparation', 'Appreciation for the intervention' 'Technical barriers to implementation' and 'social barriers to implementation'.

The intervention HOUVAST 2.0 proved engaging for clinicians that used the intervention, but also proved difficult to implement. The main barriers were a suboptimal selection process based on pharmacy refill data, a difficult target population, nurse practitioners' difficulties addressing adherence with patients and the project did not align with goals of GPs.

Conclusions: Implementation of the HOUVAST 2.0 intervention in the Dutch primary care proved challenging. A good established collaboration between GPs and pharmacies, better ICT applications for selecting patients and a training more aimed towards practical

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

communication techniques are important improvements needed for further implementation.

4771 | Antipsychotic treatment changes in incident parkinsonism treated with levodopa

Sibylle de Germay[1], Olivier Rascol[1,2], Jean-Louis Montastruc[1,2] and Maryse Lapeyre-Mestre[1,2]
[1]*Service de Pharmacologie Médicale et Clinique, Centre Hospitalier Universitaire de Toulouse, Toulouse, France;* [2]*CIC INSERM 1436, Centre Hospitalier Universitaire de Toulouse, Toulouse, France*

Background: Neurodegenerative parkinsonisms like Parkinson's disease were treated by dopatherapy to improve motor symptoms caused by dopamine deficit. Psychotic symptoms were found in 40-60% of Parkinson's disease patients. Treating these symptoms by antipsychotics is difficult since these drugs block dopaminergic receptors, leading to worsening motor symptoms. Antipsychotics induce secondary parkinsonisms but their population-attributable fraction of PD was also estimated at 21.7% in a French cohort study. Continuation of antipsychotics after parkinsonism diagnosis leads to a risk of dopaminergic and anti-dopaminergic co-prescriptions.
Objectives: The study aimed to investigate if the start of parkinsonism healthcare went along with changes in antipsychotic use.
Methods: A repeated monthly cross-sectional study was performed between 2006 and 2017, using data of patients with incident levodopa-treated parkinsonism from the French national health database. A six-month lag was introduced before the start of parkinsonism healthcare (defining the diagnosis date) since it is a period of an overall increase in health care consumption. The two years preceding this lag time defined the "pre-diagnosis" period and the two years after the diagnosis defined the "post-diagnosis" period. The number of patients exposed to at least one antipsychotic was measured monthly during the two periods and viewed with streamgraphs.
Results: During the study period, 1,258 patients with incident parkinsonism were identified (mean age 76.6 years ±9.2; 50% of women). During the pre-diagnosis period, 13.6% of patients were exposed to antipsychotics and 14% during the post-diagnosis period. Risperidone was the first used followed by cyamemazine, tiapride and haloperidol. No major changes in terms of antipsychotic classes were observed after the start of dopatherapy, with the exception of a decrease in sulpiride and levomepromazine use. Antipsychotics introduced in the post-diagnosis period were mainly tiapride, risperidone and clozapine. Patients exposed to both antipsychotics and dopatherapy in post-diagnosis period represented 14% of the study population.
Conclusions: This population-based study revealed a high antipsychotic exposure in parkinsonian patients during the "pre-diagnosis" and "post-diagnosis" periods without major changes in terms of antipsychotic classes after dopatherapy beginning. These practices led to a frequent co-prescription of antipsychotics and dopaminergic drugs, reflecting the difficulties encountered by practitioners in treating psychosis associated with neurodegenerative parkinsonism.

4794 | Association between digoxin use and SCD in individuals with the rs10494366 variant of the NOS1AP gene: The Rotterdam study

Negin Soroush, Albert-Jan Aarnoudse, Fereshteh Shokri, Marten Van den Berg, Fariba Ahmadizar and Bruno Stricker
Erasmus University Medical Center, Rotterdam, Netherlands

Background: Digoxin is one of the oldest cardiovascular medications still used to treat heart failure and atrial fibrillation. Due to its narrow therapeutic window, it is associated with life threatening intoxication and arrhythmias, and with QTc-shortening. Common genetic variation in the nitric oxide synthase-1 adaptor protein (NOS1AP) has been associated with QTc interval prolongation and sudden cardiac death (SCD).
Objectives: We investigated whether the rs10494366 variant of the NOS1AP gene modified the risk of SCD in patients using digoxin
Methods: Design: A prospective population-based cohort study **Setting:** The Rotterdam Study (RS). We included data of the three (RS) cohorts, started as of January 1st, 1991 until January 1st 2014. **Exposures**: Digoxin current use on the date of cardiac death in cases and the same day of follow-up in the remainder of the cohort as a time-dependent variable. **Main outcome**: SCD defined as sudden and unexpected death as a result of cardiac causes, according to international criteria. Identification and adjudication of SCD was performed independently, before the start of this study. **Statistical analysis:** We used Cox proportional hazard regression analysis to investigate the associations between NOS1AP rs10494366 variant and incident SCD among digoxin users and non-users. Associations were adjusted for age, sex and BMI, prevalent diabetes, myocardial infarction, baseline hypertension and smoking status (past, current, never).
Results: We included 14,594 individuals, with a mean age of 65.3 (SD 10.3) years. Almost 59% were female. The cumulative incidence of SCD was 9.5% (609 cases) by the end of follow up. Among them, 98 (16%) individuals were exposed to digoxin at the time of death. In model 1 adjusted for age and sex, NOS1AP rs10494366 variant was not associated in the total study population. However, an interaction term of the gene with the daily dose of digoxin was significantly associated with increased risk of SCD (p-value 0.0001). The risk of SCD in current users of digoxin was 4.2 [95% CI 1.3-13.8] for the GG genotype; for the GT genotype, the risk was 2.1 [95%CI 1.1-4.2]; and for the TT genotype was 1.5 [95%CI 0.7-3.2] in fully adjusted models.
Conclusions: NOS1AP rs10494366 variant modified the risk of SCD in users of digoxin. Individuals with the homozygous minor GG allele had a fourfold increased risk of SCD.

4812 | Factors associated with switching from oral glucose-lowering medications to insulin therapy in type 2 diabetes: The Rotterdam study

Payam Peymani[1], Marten van den Berg[2], Bruno Stricker[2] and Fariba Ahmadizar[2]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]Department of Clinical Pharmacology & Toxicology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Little is known about factors associated with the decision to switch from oral use to insulin in type 2 diabetes (T2D) patients.

Objectives: Therefore, we investigated factors associated with switching from oral glucose-lowering medications to insulins therapy as a proxy for diabetes progression.

Methods: ***Study design:*** A longitudinal prospective cohort study ***Study Setting:*** Rotterdam Study For this study, we included all pharmacologically treated T2D patients (n=1590). The primary endpoint was switching from oral glucose-lowering medications to insulin therapy. We defined 'switchers' as subjects who switched to insulin therapy (ATC code A10A) with or without continuation of oral glucose-lowering medication. We assessed the association between switching and patients' characteristics including age, gender, body mass index (BMI), waist circumference (WC), smoking, systolic blood pressure (SBP), diastolic blood pressure (DBP), socio-economic status, physical activity, lipids and C-reactive protein (CRP). A modified Cox regression analysis (Fine-Gray model) considering death as the competing risk was used, providing sub-distribution hazard ratio (SHR) and 95% confidence interval (CI).

Results: Mean (SD) age was 67.0 (10.5) years. Almost 56% of patients were females and 41% were obese (BMI≥30 kg/m^2). The frequency rate of switching was 45.1% over a mean follow-up of 4.8±4.2 years. Patients who died during the follow-up study were significantly older than the switchers (p=0.01). Switchers had a higher mean of BMI (p=0.01), and higher systolic blood pressure (SBP) (p=0.01). In univariate analyses age (SHR: 0.96, 95% CI: 0.95 - 0.97), BMI (1.03: 1.02-1.05), WC (1.01: 1.00-1.02), and SBP (1.01: 1.00-1.02) were statistically significantly associated with switching. However, in multivariable adjusted models, the associations were no longer significant except for age.

Conclusions: We showed different individual factors which were associated with switching from oral use to insulin in population with T2D. Our study highlights that insulins added to the standard oral glucose-lowering medication are mainly used in younger T2D patients.

4817 | Preventive effect of antiplatelet salicylates in individuals with type 2 diabetes - The Rotterdam study

Fereshteh Shokri, Negin Soroush, Bruno Stricker and Fariba Ahmadizar

Erasmus University Medical Center, Rotterdam, Netherlands

Background: Antiplatelet salicylates are commonly used for prevention of cardiovascular disease (CVD) in general population. Type 2 diabetes mellitus (T2D) has unfavorable consequences on blood vessels, including macro and microvascular diseases. Although Antiplatelet salicylates are approved agent used to prevent CVD in diabetic patients, there are some patients who do not respond to this medication.

Objectives: We aimed to investigate if low dose antiplatelet salicylates prevent incident CVD by comparing free of diabetes individuals and T2D patients.

Methods: Design: A longitudinal cohort study. Setting: Prospective population-based Rotterdam Study (RS), the Netherlands. We included data of the three (RS) cohorts, starting from March 1997 to January 2015. Exposures: Current use of low dose Carbasalate Calcium or Acetylsalicylic acid (100 mg/day or lower). Main outcome: Incidence of any CVD events defined as a composite endpoint of: myocardial infarction (MI), coronary heart disease (CHD), heart failure (HF), Stroke or CVD mortality during follow-up. Prevalent cases of MI, CHD, HF, and stroke at baseline were excluded from the analyses. Statistical analysis: We applied Cox regression analysis to determine adjusted hazard ratios (HR) and 95% Confidence intervals (CI) for the association of current use of Antiplatelet salicylates and incident CVD among free of diabetes individuals and T2D patients at baseline. We also studied the effect of different Antiplatelet salicylates duration (0, 1-90, 91-365, >366 days) on incident CVD. Associations were adjusted for age, sex, and baseline measurements of BMI, hypertension and smoking status.

Results: We included 8333 individuals free of diabetes, and 1044 with T2D at baseline. Median follow up time was 28 years. In total, At baseline, the mean age (SD) was 64 (9.6) years and 39.7% were men. Mean (SD) BMI was 27.2 (5.5) kg/m^2. The Current use of antiplatelet salicylates was associated with a significantly decreased incidence of any CVD. We found a significant association of antiplatelet salicylates duration of use with incident CVD. longer duration (> 366 days) was associated with significantly increased risk of incident CVD in both free of diabetes [HR=1.44; 95%CI: 1.29-1.61] individuals and T2D [HR=1.38; 95%CI: 1.08-1.76] patients.

Conclusions: Long term antiplatelet salicylates use was not associated with decreased risk of incident CVD among both diabetic and non-diabetic populations. Our study suggests no protective effect of antiplatelet salicylates use, particularly among patients at higher risk of CVD (i.e. type 2 diabetes).

4868 | Impact of the food and drug administration safety warnings and removal of indications for use of oral quinolones

Phuong T. Tran[1,2], Patrick J. Antonelli[2,3], Juan M. Hincapie-Castillo[1,2] and Almut G. Winterstein[1,2]

[1]Department of Pharmaceutical Outcomes and Policy, College of Pharmacy, University of Florida, Gainesville, FL; [2]Center for Drug Evaluation and Safety, University of Florida, Gainesville, FL; [3]Department of Otolaryngology, College of Medicine, University of Florida, Gainesville, FL

Background: In Nov 2015, concerns of systemic quinolones' risks outweighing benefits led an FDA advisory committee to advise removing

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

indications for acute, uncomplicated urinary tract infection (uUTI), acute sinusitis (AS) and acute exacerbation of chronic bronchitis (AE-COPD). In May 2016, the FDA released a safety communication, requiring label changes, which were implemented in Jul 2016.

Objectives: To assess the impact of oral quinolone (OQ) label changes on utilization in uUTI, AS, AE-COPD.

Methods: This was a trend analysis (Jan 2013 – Nov 2018), using the IBM MarketScan Commercial Claims and Medicare Supplemental Database. For each study month, we assembled 3 cohorts of adults diagnosed with uUTI, AS or AE-COPD who had oral antibiotics (Abx) dispensed within +/-5, +/-14 or +/-5 days, respectively. Patients had to be enrolled -365/+30 days before diagnosis. We excluded patients with conditions that complicate infections (e.g. spinal injury) within -365/+30 days and who hospitalized or had other infections within -90/+30 days. Monthly OQ prevalence was measured as # of OQ per 100 Abx-treated infection episodes. We used interrupted time series to compare the OQ prevalence before and after label changes. Sensitivity analysis used the implementation period from Nov 2015-Jul 2016 to define pre- and post-periods. We used segmented ordinary least-square regression with Newey-West autocorrelation adjustment and controlled for seasonality. We stratified OQ trend by provider types and evaluated shifting treatment pattern to other abx.

Results: In Jan 2013, the OQ prevalence among abx-treated uUTI episodes was 41.21 (40.96; 41.47); among AS 12.05 (11.67; 12.42); and among AE-COPD 34.3 (33.53; 35.16). Before OQ label changes, trends of absolute changes in OQ use prevalence were flat for uUTI -0.08 (-0.09; -0.07); AS -0.06 (-0.08; -0.04); and AE-COPD 0 (-0.05; 0.05). Right after OQ label changes, an immediate absolute reduction was found for uUTI -6.09 (-7.92; -4.26); AS -1.80 (-2.44; -1.16); and AE-COPD -3.41 (-5.66; -1.17). Monthly utilization trends continued to decrease thereafter. Treatment pattern shifted mostly to 1st line Abx (nitrofurantoin in uUTI, amoxicillin/clavulanate in AS; macrolides in AE-COPD), but use of 2nd line or not recommended Abx also increased. OQ prescribing prevalence varied across prescribers, but significant reductions were seen across all provider types.

Conclusions: The label changes had a strong impact on OQ utilization for removed indications. The magnitude of decrease varied by conditions and prescriber specialty.

4916 | Valproate utilisation trends among women of childbearing potential in Ireland between 2014 and 2017: A drug utilisation study using interrupted time series

John Hughes[1], Maeve Mullooly[1], Niamh Buckley[2], Yvonne Looney[2] and Kathleen Bennett[1]

[1]*Royal College of Surgeons in Ireland, Dublin 2, Ireland, Dublin, Ireland;* [2]*Health Products Regulatory Authority, Earlsfort Terrace, Dublin 2, Ireland, Dublin, Ireland*

Background: Use of valproate (VPA) during pregnancy is associated with increased risk of congenital malformations and neurodevelopmental disorders in exposed unborn children. Following an EU-wide safety review in 2014, the European Medicines Agency strengthened the warnings on VPA use in women of childbearing potential (WCBP), which was communicated to healthcare professionals and patient organisations in Ireland.

Objectives: To examine the trends in prevalence of VPA use among women aged 16-44 years in Ireland between 2014 and 2017 and the effect of regulatory intervention on these prevalence trends.

Methods: National pharmacy claims data identified prescriptions dispensed for women aged 16-44 years, and by 10 year age-groups (16-24, 25-34 and 35-44 years), from community pharmacies in Ireland between January 2014 and December 2017. Using annual population estimates, the prevalence rate of VPA use was calculated based on the number of women per month in receipt of VPA per 1000 eligible women in Ireland. Segmented regression analysis of interrupted time series was used to examine slope changes in monthly prevalence rates of VPA use before and after regulatory intervention (pre- and post-December 2014).

Results: Overall, the rate of VPA use among those aged 16-44 years from January 2014 (2.06/1000) to December 2014 (2.06/1000) was stable, however, there was a non-significant overall decrease in subsequent months to December 2017 (1.80/1000; p=0.077). Analysis stratified by age-groups found that the post-intervention decrease was only significant in the youngest 16-24 year age-group, where the rate of VPA use between January 2014 and December 2014 remained stable (1.60/1000), but was seen to decrease in the months following regulatory intervention (1.20/1000 as of December 2017; p=0.009).

Conclusions: There is evidence that changes in use of VPA among WCBP, particularly those aged 16-24 years, were observed following targeted regulatory intervention. Future research should examine the impact of the 2018 EU-wide safety review on VPA use in this cohort.

4943 | Low-dose aspirin use for primary or secondary prevention of cardiovascular diseases in patients with type 2 diabetes

Payam Peymani[1], Najmeh Maharlouei[2], Azra Izanloo[3], Amir Hooshang Mohammadpour[4], Abbas Rezaianzadeh[5] and Fariba Ahmadizar[6]

[1]*Department of Clinical Pharmacology & Toxicology, University Hospital Zurich, Zurich, Switzerland;* [2]*Health Policy Research Center, Institute of Heath, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran;* [3]*Razavi Cancer Research Center, Razavi Hospital, Imam Reza International University, Mashhad, Islamic Republic of Iran;* [4]*Department of Clinical Pharmacy, School of Pharmacy, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran;* [5]*Department of Epidemiology, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran;* [6]*Department of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands*

Background: Whether Low-Dose Aspirin (LDA) is indicated for primary or secondary prevention of cardiovascular diseases (CVD) in population with type 2 diabetes mellitus (T2DM) remains unclear.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Moreover, if gender plays a role in LDA indication has not been studied.

Objectives: To compare the indication of LDA use for primary and secondary prevention of CVD in patients with T2DM.

Methods: *Study Design:* Cross-sectional analysis *Study Setting:* The large prospective population-based Kharameh Study in Iran that includes 10,688 individuals aged 40 to 70 years *Data Analysis:* We included 1,607 patients with T2DM. Chi-square test was applied to compare prevalence rate of LDA indicated as <100 mg/daily in diabetic patients with CVD (secondary prevention) and without CVD (primary prevention); CVD defined as presence of myocardial infarction, myocardial ischemia, chronic heart disease, heart failure or stroke. In gender-stratified analysis, we further studied the effect of gender on this indication.

Results: Prevalence rate of T2DM was higher among women (71.3%) compared to men. Mean (SD) age was 58.6 (7.2) years; mean (SD) body mass index was 27.1 (4.1) and CVD was prevalent as 21.0%. Prevalence rate of T2DM patients on LDA use was 22.4%, with no significant difference between men and women (p=0.47). 59.3% of diabetic patients were using LDA for secondary prevention of CVD, shown as statistically significantly (p<0.001) higher rate compared to those taking LDA for primary prevention (12.6%).

Conclusions: LDA is most common for secondary prevention of CVD in patients with T2DM. Gender has no effect on this indication. Given that LDA is used to prevent CVD, longitudinal studies are needed to clarify the efficacy and safety of this indication in patients with T2DM.

5001 | Utilization of oral anticoagulants in patients with venous thromboembolism

Geetha Iyer[1,2], Ajinkya Pawar[1], Chandrasekar Gopalakrishnan[1], Helen Tesfaye[1], Kristyn Chin[1], Joshua J. Gagne[1,2] and Katsiaryna Bykov[1]
[1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Harvard T H Chan School of Public Health, Boston, MA

Background: Introduction of direct-acting oral anticoagulants (DOACs) has transformed the treatment of venous thromboembolism (VTE). Real-world data offer valuable insight into how anticoagulants are utilized in clinical practice and may aid in understanding reasons for changes in therapy.

Objectives: To 1) evaluate prescribing patterns of oral anticoagulants in patients with VTE, 2) assess measures of adherence and persistence, and 3) identify clinical events that precede discontinuation or switching.

Methods: We used claims from US Medicare and IBM MarketScan Commercial databases (2010 – 2017) to characterize patients initiating oral anticoagulant within 90 days of discharge from VTE hospitalization (index event). We plotted trends in oral anticoagulation initiation and compared profiles of patients initiating warfarin vs. DOACs (rivaroxaban, dabigatran, apixaban and edoxaban) over time. Patterns of anticoagulant discontinuation (≥ 30 days treatment gap) and switches, proportion of days covered (PDC) during the 365 days after initiation, and time on anticoagulant therapy (median and interquartile range, IQR) were assessed. We also identified clinical events in the 30 days preceding changes in therapy.

Results: 234,020 patients (Medicare - 153,063; MarketScan - 80,957) initiated an oral anticoagulant after their index VTE; 100% initiated warfarin in 2010 and 27% initiated warfarin, 33% rivaroxaban, and 37% apixaban in 2017. Patients initiating warfarin were more likely to have hypertension, diabetes mellitus, anemia, and history of kidney disease compared to those initiating DOACs. Median duration of treatment was 172 days (IQR 76 - 326) and 167 days (IQR 80 - 278) in Medicare and MarketScan, respectively, and was similar regardless of whether the index event was provoked. Patients with pulmonary embolism as the index event persisted longer on treatment than those with deep vein thrombosis. The overall 365-day PDC with any oral anticoagulant was 0.55 ± 0.30 in Medicare and 0.51 ± 0.29 in MarketScan. Approximately 25% discontinued and 9% patients switched anticoagulant therapy within a year. Switching to another anticoagulant was preceded by codes for VTE diagnostic procedures, atrial fibrillation, or ischemic stroke among 30% of MarketScan and 32% of Medicare patients.

Conclusions: Most patients with VTE continued anticoagulant treatment for approximately 6 months and clinical reasons for modifying anticoagulant therapy were identified in a third of patients. Information on why and how treatments are adapted in clinical practice is crucial for generating valid evidence on drug safety and effectiveness.

Drug Utilization Research -> Health policy and governance

57 | Methods to evaluate the effects of policy changes during the opioid crisis

Juan M. Hincapie-Castillo[1], Amie J. Goodin[1], Gerald J. Dal Pan[2], Mina Tadrous[3]
[1]University of Florida, Gainesville, FL; [2]Food and Drug Administration, Silver Spring, MD; [3]University of Toronto, Toronto, ON, Canada

Background: Attempts to mitigate the opioid abuse epidemic in North America have resulted in an abundance of policies aimed mainly towards control of drug supply. Drug utilization research (DUR) tools are useful in assessing these policies; however, the framing of research questions for evaluation throughout the continuum of the health policy process requires further considerations for correct causal inference and for successful translation of results to stakeholders. Lessons learned from the evaluations of opioid policies can inform future studies in other areas.

Objectives: We aim:

1). To provide an overview of the health policy process as applied to the rapidly evolving challenges of the opioid crisis.

2). To assess strengths and limitations in both established and emerging novel policy evaluation methods, and accompanying measurement challenges for opioid-related research.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

3). To examine applications of these methods in current studies estimating effects of drug-related policies using examples from the US and Canada.

Overall, this symposium will benefit researchers and policymakers interested in learning strategies for addressing methodologic challenges when designing a policy evaluation.

Description: The symposium will be divided among four panel speakers, with 20 minutes each. The opioid crisis will serve as the motivating case throughout the symposium, where a sampling of the multitude of policies and respective methodological considerations are woven throughout each presentation. First, Amie Goodin will introduce policy theory through the lens of a legal epidemiology framework to set the stage for planning evaluations in the context of the opioid crisis. Juan Hincapie-Castillo will then give an overview of DUR policy evaluation methods that can be applied to specific research questions using real-world data, where methodological challenges in evaluating policy implemented at the health-system, state, and/or national levels are addressed. Gerald Dal Pan will then discuss measurement challenges in policy evaluation when estimating opioid utilization as well as the outcomes associated with the opioid and related poly-substance abuse epidemic. Lastly, Mina Tadrous will provide applied examples of Canadian policy evaluations, outlining the unique challenges associated with traditional (e.g., time series strategies, difference-in-differences techniques) and emerging novel policy evaluation methods (e.g., the potential for dynamic compartmental modeling techniques, structural break models and machine learning applications). The session will conclude with a 10-minute Q&A from panel members.

2400 | Inequities in primary care attachment among people receiving opioid therapy

Tonya Campbell[1], Richard Glazier[1,2,3], Laura Robertson[2], Diana Martins[2], J. Michael Paterson[1,3], David Juurlink[1,3,4], Muhammad Mamdani[1,3,5] and Tara Gomes[1,2,3]

[1]ICES, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [5]Unity Health Toronto, Toronto, ON, Canada

Background: Qualitative evidence has indicated that people in Ontario, Canada who use opioids for managing chronic pain, or for opioid agonist therapy, may experience difficulties securing a primary care provider (PCP) and may seek care in an emergency department (ED) as a substitute.

Objectives: To compare rates of re-attachment to primary care and ED visits for people receiving opioid therapy relative to people with no recent opioid exposure.

Methods: In this population-based cohort study, we identified Ontarians whose enrolment with a PCP was terminated between January 2016 and December 2017, and classified individuals as opioid agonist therapy (OAT) recipients, chronic pain-related opioid therapy (COT) recipients, or people without recent opioid exposure. Our primary outcome was the rate of primary care re-attachment, defined as attachment to an enrolment model, community health centre, or fee-for-service physician. Our secondary outcome measured the rate of ED visits during the period without primary care attachment. Cox and Poisson models were used to compare outcomes between the groups exposed to opioids and the group unexposed.

Results: We identified 1,759 OAT recipients, 3,891 COT recipients, and 150,890 opioid unexposed individuals whose PCP enrolment was terminated. At 1-year follow-up, OAT recipients had a lower rate of primary care re-attachment (adjusted Hazard Ratio [aHR] 0.54; 95% CI 0.49-0.59), and COT recipients had a similar re-attachment rate (aHR 0.96; 95% CI 0.92-1.01), compared to opioid unexposed individuals. When considering enrolment models alone, both groups had a lower re-attachment rate compared to people without opioid exposure (OAT recipients: aHR 0.35; 95% CI 0.31-0.41, COT recipients: aHR 0.86; 95% CI 0.81-0.91). Relative to opioid unexposed individuals, the rate of ED visits was greater among OAT recipients (adjusted rate ratio [aRR] 1.23; 95% CI 1.16-1.30) and COT recipients (aRR 1.37; 95% CI 1.31-1.43), during the period without attachment.

Conclusions: Compared to the opioid unexposed individuals, people who use opioids face inequities in primary care attachment, particularly to enrolment models. Furthermore, the higher rates of ED visits among these individuals may indicate unmet health needs. Barriers to accessing primary care among people using opioids must be addressed by clinicians and policymakers.

2550 | Ability of primary healthcare records to assess medicinal products discussed by the pharmacovigilance risk assessment committee

Robert Flynn[1,2], Karin Hedenmalm[1], Tarita Murray-Thomas[3], Alexandra Pacurariu[1], Peter Arlett[1], Hilary Shepherd[3], Puja Myles[3] and Xavier Kurz[1]

[1]European Medicines Agency, Amsterdam, Netherlands; [2]University of Dundee, Dundee, United Kingdom; [3]Clinical Practice Research Datalink, London, United Kingdom

Background: The EU's Pharmacovigilance Risk Assessment Committee (PRAC) is responsible for protecting patients by ensuring the safety of marketed medicines. The European Medicines Agency (EMA) supports such evaluation by analysing routinely collected Primary care Health Records (PHRs) to assess drug utilisation, risks of medicines and effectiveness of risk minimisation measures.

Objectives: To evaluate the capture of exposure to medicines discussed at PRAC in four established PHR databases.

Methods: Four PHR databases were searched for substances discussed at consecutive PRAC meetings from September to November 2018: IQVIA Medical Research Data (IMRD) - France, IMRD - Germany, IMRD - United Kingdom and the Clinical Practice Research Datalink Aurum. Data extracted were: number of prescriptions, number of patients with at least one prescription, whether a Centrally (CAP) or Nationally (NAP)

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Authorised Product and authorisation date. Exposures were assessed up to 31 August 2018. To estimate the number of substances each database could meaningfully assess adverse events, we calculated the numbers of patient exposures required to detect a statistically significant event associated with a theoretical relative risk of 2.0, with adverse event rates taken from the Summary of Product Characteristics frequency categories. This was based on a hypothetical comparison of two proportions using a 2-sided Fisher test with $\alpha = 0.05$, power = 0.90 and equal numbers of exposed/comparator patients.

Results: There were a total of 128 drug substances (or classes): 83 CAPs (64.8%) and 45 NAPs (35.2%). Of CAPs, 6 (7.2%) had been authorised for < 2 years, 20 (24.1%) for 2-5 years and 57 (68.7%) for > 5 years. Where marketed (n = 41), all NAPs had been authorised for > 5 years. No individual database was able to detect a doubling in effect size for the majority of CAPs for *common* (1/100), *uncommon* (1/1000), *rare* (1/10000) or *very rare* (1/100000) events, or NAPs for *uncommon*, *rare* or *very rare* events. An analysis of pooled allowed the detection of an *uncommon* adverse event associated with a doubling of risk for 26.5% of CAPs and 60.0% of NAPs. For events that were *rare* or *very rare* the proportion was lower (CAPs: 4.8% and 0%; NAPs: 40.0% and 11.1%). Coverage was worse for "orphaned" substance.

Conclusions: More advanced and recently authorised medicinal products had less coverage in the available databases compared to more established, nationally licensed products. To enable better informed regulatory decisions there is a need to access complementary data sources, particularly capturing exposure in specialist care settings.

2575 | Program churn among children enrolled in North Carolina medicaid

Alexander Breskin[1], Rushina Cholera[2], David Anderson[2], Suzanne Landi[1], Aaron McKethan[1,2] and Charlene Wong[2]
[1]*NoviSci, Durham, NC*; [2]*Duke University, Durham, NC*

Background: Retaining eligible children in public insurance is of rising concern as pediatric Medicaid/CHIP enrollment has declined in recent years. Any gaps in coverage, even short ones, lead to unmet healthcare needs for children. This coverage "churning" is also costly for public programs. Understanding program churning will be critical to prevent widening of health disparities as North Carolina (NC) is poised to implement dramatic payment and care delivery reforms, including the value-based Integrated Care for Kids model.

Objectives: To describe rates and disparities in Medicaid coverage churning among NC children.

Methods: Children enrolled in NC Medicaid on January 1, 2016 (N=1,196,127) were included and followed until December 31, 2018. We used the Kaplan-Meier estimator to calculate the probability of continuous enrollment and the time to reenrollment among those with a coverage gap of ≥1 month. Children who reenrolled within 6 months of disenrollment were assumed to have been continuously eligible for coverage and were classified as having experienced churning. Disparities in churning were assessed by demographic characteristics.

Results: 90.4% of children remained continuously enrolled for 1 year, 81.3% for 2 years, and 73.6% for three years. Adolescents ages 16-18 were less likely to remain continuously enrolled for 2 or 3 years (60.2-73.4%) compared to younger children. Among children who experienced a coverage gap (N= 315,217), 17.0% churned (i.e., reenrolled within 6 months), 9.2% reenrolled within 7-11 months, and 73.8% did not reenroll for one year or more. Of the White children who experienced a coverage gap, 13.8% (95% CI: 13.6, 14.0) reenrolled within 6 months compared to 17.7% (95% CI: 17.4, 18.0) of Black children and 23.0% (95% CI: 22.7, 23.3) of Hispanic/Latinx children. Program churning was higher in children living in urban areas (20.4% [95% CI: 20.1, 20.7]) compared to those living in rural (17.4% [95% CI: 17.1, 17.6]) and suburban (17.8% [95% CI: 17.5, 18.2]) areas.

Conclusions: Most Medicaid insured children remained continuously enrolled for at least a year with almost 75% experiencing 3 years of continuous enrollment. Among children who experienced a coverage gap, 17% churned with reenrollment within 6 months. Higher rates of churn among minority children and children living in urban areas can inform how the allocation of limited resources to reduce coverage instability.

2577 | Utilization of hydroxyprogesterone during the second and/or third trimester among pregnancies with live birth deliveries in the sentinel distributed database

Huei-Ting Tsai[1], Mayura Shinde[2], Austin Cosgrove[2], Jie Li[1], Christina Chang[1], Christine Nguyen[1], Corinne Woods[1], Joy Kolonoski[2], Tiffany Woodworth[2] and David Moeny[1]
[1]*U.S. Food and Drug Administration, White Oak, MD*; [2]*Harvard Pilgrim Health Care Institute, Boston, MA*

Background: Makena®, hydroxyprogesterone caproate (HPC) injection, is indicated for reducing the risk of preterm birth in women with a singleton pregnancy who had a prior singleton spontaneous preterm birth. The U.S. FDA approved Makena on February 3, 2011 under accelerated approval, contingent upon post-marketing confirmation of clinical benefit, such as improvement in neonatal mortality and morbidity. The confirmatory trial failed to confirm Makena's efficacy. An analysis of drug utilization of HPC, including Makena, in pregnant women was undertaken to inform the landscape of HPC use for deliberations at the FDA's Advisory Committee meeting on Makena.

Objectives: To assess the utilization of HPC in pregnancy in the U.S.

Methods: We identified pregnant women aged 10-54 years, with a live birth from January 1, 2008 through April 30, 2018, and with continuous medical and drug insurance coverage for at least 301 days prior to a live birth delivery in the Sentinel Distributed Database (SDD). The exposures of interest included use of injectable HPC (Makena and its generics) and compounded HPC from bulk power during the 2nd or 3rd trimesters. We assessed three obstetrical

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

conditions of interest as potential reasons for use: (1) history of preterm delivery, (2) preterm labor in the current pregnancy, and (3) cervical shortening in the current pregnancy. We evaluated the temporal trend of HPC use over the study period. Among pregnancies with injectable HPC use, we calculated the percentage of those with diagnoses for each related obstetrical condition; and the percentage of pregnancies with diagnoses for any of three related obstetrical conditions.

Results: We identified a total of 3,451,121 live-birth pregnancies (among 2,912,911 women) between 2008 and 2019 in the SDD. Of these pregnancies, 16,535 showed use of injectable HPC during the 2nd or 3rd trimesters. The yearly proportion of pregnancies with injectable HPC use increased over the study period from 0 in 2010 to 13 per 1,000 pregnancies in 2018; use of compounded HPC decreased from 4 to 0.25 per 1,000 pregnancies over the same time. Of 16,535 pregnancies with injectable HPC use, 6,443 (39%) had recorded history of preterm delivery and 12,060 (73%) had at least one related obstetrical condition.

Conclusions: We found modest use (about 1.3% in 2018) of HPC during the 2nd or 3rd trimesters of live-birth pregnancies in SDD. A high percentage (73%) of pregnancies with injectable HPC use had at least one obstetrical indication of interest.

2617 | Prescribing trends of direct acting antivirals for the treatment of hepatitis C in Ontario

Mina Tadrous[1], Kate Mason[2], Bernadette Lettner[3], Mary Guyton[2], Zoë Dodd[2], Jeff Powis[3], Diana Martins[4] and Tara Gomes[4]
[1]Women's College Hospital, Toronto, ON, Canada; [2]South Riverdale Community Health Centre, Toronto, ON, Canada; [3]Toronto Community Hep C Program, Toronto, ON, Canada; [4]Ontario Drug Policy Research Network, Toronto, ON, Canada

Background: The ease and effectiveness of direct acting oral antivirals (DAAs) treatments provide opportunity to expand treatment for chronic hepatitis C (HCV). Reimbursement mechanisms for DAAs have changed on two occasions since these drugs were added to Ontario' publicly funded drug formulary. Whether these changes have appreciably modified prescribing patterns and increased access to DAAs is unknown.

Objectives: The purpose of this study was to summarize the utilization of DAAs in Ontario between 2012 and 2018, and describe changes in prescribing physician specialties. A secondary objective was to describe the characteristics of people who received treatment through public reimbursement in 2018.

Methods: We conducted a repeated cross-sectional study for DAAs reimbursed by the public drug program in Ontario from January 1, 2012 to December 31, 2018. We measured the quarterly number of users, overall and by prescriber specialty. Characteristics of those receiving DAA treatments in 2018 were examined overall and by prescriber specialty.

Results: A total of 27,116 individuals received a publicly-funded DAA prescription between Q1-2012 and Q4-2018. Nearly two-thirds (n=17,813; 65.7%) of all DAAs were prescribed by gastroenterologists, hepatologists or infectious disease specialists. Only 9.6% of DAA recipients were treated by general practitioners. Utilization of DAAs had three major phases of increased uptake: (1) the introduction of DAAs to Ontario's public drug formulary as a prior authorization benefit in Q1-2015; (2) expanded listing of DAAs as limited use products on the formulary in Q1-2017; and (3) the introduction of newer DAAs in Q2-2018. In 2018, 2,538 unique individuals received publically funded DAAs. The majority were over age 50 (59.8%), male (63.8%) and living in urban (88.8%) neighborhoods of lower socioeconomic status (41.7% in lowest income quintile neighborhoods). There were important differences among patients who received treatment from gastroenterologists/hepatologists (GH). For example, patients who received treatment from a general practitioner (GP) or infectious disease specialist (IDS) were more likely to have a mental health diagnoses (GP: 77.7%; IDS: 71.2% v GH: 41.6%) and be receiving opioid agonist therapy (GP: 54.5%; IDS: 51.6% v GH: 12.4%).

Conclusions: HCV elimination guidelines call for an expansion of the range of who delivers HCV treatment. Changes in the listing criteria of DAAs in Ontario's public drug program has led to increased uptake of these agents. However, there does not appear to be increased prescribing of DAAs among.

2622 | Impact of two recent major drug shortages on drug utilization

Mina Tadrous[1], Katie Suda[2] and Tara Gomes[3]
[1]Women's College Hospital, Toronto, ON, Canada; [2]University of Pittsburgh, Pittsburgh, PA; [3]Unity Health Toronto, Toronto, ON, Canada

Background: Over the last decade the number of drug shortages has dramatically increased in Canada and worldwide. **Between 2015 to 2017, there were over 1,000 reported drug shortages** and the annual number appears to be increasing. Two recent major shortages occurred impacting access to bupropion and valsartan- two very commonly used treatments.

Objectives: To measure the impact of product shortages on drug utilization of two recent drug shortages in Ontario Canada.

Methods: We conducted a repeated cross-sectional study of bupropion and valsartan between July 1, 2012 and March 31, 2019. Both drugs experienced a significant drug shortage in 2018 and 2019, respectively. Using the public claims data in Ontario. We analyzed the quarterly number of drug claims for each of these medications. We analyzed all drugs including those impacted and not impacted by the specific shortage. We reported the number of claims quarterly for each drug class before and after the drug shortage occurred.

Results: We found that the number of claims for bupropion did not significantly decrease after the drug shortage was reported in Q1-2018, with the number of claims only slightly plateauing at 236,017 claims and no significant reduction in the trend. In contrast, valsartan claims dropped dramatically from 191,732 claims after the shortage occurred to 56,548 claims in Q1-2019, a 71% reduction.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Our results highlight the variable impact of shortages on utilization. Although both drug shortages were prolonged in their limitation of products the extent and number of products affected may greatly influence the impact of the drug shortage. This work highlights potential differences in drug shortages that should be used to inform policies to help curb the growing problem.

2634 | Estimating the impact of prescribing limits on prolonged opioid use following surgery

Jessica C. Young[1], Nabarun Dasgupta[1], Virginia Pate[1], Til Sturmer[1], Brooke A. Chidgey[2] and Michele Jonsson Funk[1]
[1]*University of North Carolina, Chapel Hill, NC;* [2]*University of North Carolina School of Medicine, Chapel Hill, NC*

Background: In response to concerns about opioid addiction, some states now limit the days supplied (DS) for initial postoperative prescriptions. However, few studies have examined the impact of these policy changes on prolonged opioid use in the population.
Objectives: To a) examine the gradient of risk of prolonged postsurgical opioid use based on the initial prescription duration, and b) estimate the potential impact of varying prescribing limits on risk of prolonged postsurgical opioid use.
Methods: We used a 20% random sample of Medicare claims (2007-2016) to identify opioid naive patients undergoing invasive surgery. Prolonged use was defined as at least 1 Rx in each of 3 consecutive 30-day windows immediately following surgery. We calculated 90-day risk of prolonged use comparing patients at a given DS level to patients receiving longer initial prescriptions. Adjusted risk differences (aRD) were obtained via standardized mortality ratio weights (adjusted for demographics, surgical characteristics, baseline medication use and comorbidities), comparing patients with a Rx greater than a given prescribing limit versus those at the limit. Estimated number of averted cases was also quantified.
Results: We identified 749,269 patients who received a perioperative opioid (median DS=5, mean age=73yr, 44% male). The overall risk of prolonged use was 14.0 (95%CI: 13.7, 14.3) per 1000 exposed patients, increasing with days supplied (14.7 for >2 days to 34.4 for >15 days). Among patients with >2 DS (n=615,490; 92%), we estimated 3.3 (1.0, 5.6)/1000 additional cases of prolonged opioid use compared to those receiving 2 DS. Among patients receiving >7 days (n=143,408; 22%), a common limit in state laws, the aRD was nearly null (-0.1/1000). At 15+ days (n=21,382; 3%), we estimated 3.5 (-0.6, 7.6)/1,000 additional cases compared to those receiving exactly 15 days. The estimated number of potentially averted cases of prolonged opioid use ranged from 10,144 (2 days) to 373 (15 days).
Conclusions: We illustrate a method to examine potential impacts of prescribing limits. While risk of prolonged postsurgical opioid use increased as patients received larger initial DS, the number of prolonged use cases theoretically preventable by prescribing limits differed by orders of magnitude depending on the number of patients above the proposed limit. While most laws focus on DS limits, results for quantity and dosage dispensed show similar trends and will also be presented, along with procedure specific (knee arthroplasty, hernia repair, cholecystectomy) results.

2646 | Strategies to approach the judicialization of health technology in Latin America and Caribbean

Sueli Miyuki Yamauti and Luciane Cruz Lopes
University of Sorocaba, Sorocaba, Brazil

Background: The judicialization of health technology in Brazil is a phenomenon that concerns public institutions, as it is growing, cumulative and increases inequities. In the literature, there are several suggested strategies to approach it. On the other hand, several strategies were implemented in Brazil. However, it is not known what type of arrangements for the health system they used in their implementation and whether there are similarities with those suggested in the literature.
Objectives: To analyze the feasibility of implementing the proposed strategies to approach the judicialization of health technology in Latin America and the Caribbean in the Brazilian context.
Methods: Comparative cross-sectional analysis among the 45 strategies proposals to approach the judicialization of health technology in the public sector, extracted from the literature review by Pinzón-Flórez et al. with the 78 strategies already implemented in Brazil, identified and categorized by Yamauti et al. as to the correspondence between them. The strategies were classified according to six World Health Organization's health system arrangements.
Results: Eight strategies proposed in the study by Pinzón-Flórez et al. are consistent with the Brazilian government's policies or programs; 27 are similar in terms of the activities developed by the strategies implemented in some Brazilian context and; 10 have no analogy with the strategies implemented in Brazil. The 78 strategies implemented work using at least two arrangements for health systems and 96.2% of them belong to the service delivery arrangement.
Conclusions: The proposed strategies to approach the judicialization of health technology in Latin America and the Caribbean are feasible to be implemented both in the form of government policies or programs and as institutional strategies in the Brazilian context. However, the strategies implemented are complex, encompass various health system arrangements and require a legal apparatus along with a public health system that has an integrated service delivery. These characteristics must be evaluated before implementing them in other contexts.

2688 | Impact of hydrocodone rescheduling on opioid prescribing by dentists in the United States, 2012-2017

Connie H. Yan[1], Colin Hubbard[1], Gregory S. Calip[1], Lisa K. Sharp[1], Charlesnika T. Evans[2,3], Susan Rowan[1], Jessina C. McGregor[4], Allen Campbell[5], Walid F. Gellad[6,7] and Katie J. Suda[6,7]

[4]Oregon State University, Corvalis, OR; [5]IQVIA Institute for Human Data Science, Durham, NC; [6]University of Pittsburgh, Pittsburgh, PA; [7]VA Pittsburgh Healthcare System, Pittsburgh, PA

Background: Dentists are amongst the top specialty prescribers of opioids, accounting for approximately 6.4% of all outpatient opioid prescriptions in the United States (US). In 2014, the US Drug Enforcement Administration (DEA) rescheduled hydrocodone-containing products (HCP) from schedule III to II, introducing more restricted prescribing and dispensing regulations, as a means to reduce opioid prescribing.

Objectives: To evaluate the impact of the HCP rescheduling regulation on dental prescribing of opioids in the US.

Methods: An interrupted time-series analysis examined monthly opioid prescriptions of five oral opioid classes (products containing hydrocodone, tramadol, codeine, oxycodone, morphine or fentanyl, and other) using the IQVIA Longitudinal Prescription Data from 2012 to 2017. Ordinary least-square regression models, with Newey-West standard errors to handle autocorrelation and heteroscedasticity, were used to examine the changes in prescription volume, dentist- and US population-based prescribing rates, quantity and days' supply dispensed, and morphine milligram equivalents (MME), across the opioid classes in the 33 months prior to index (regulatory change in October 2014) compared to the 39 months after index (post-period).

Results: From 2012 to 2017, dentists prescribed approximately 70 million opioid prescriptions, of which 68.9% were HCP, 18.3% codeine, 8.6% oxycodone, 3.9% tramadol, and 0.4% other. At index, HCP immediately decreased by 103,527 prescriptions, with increases in prescriptions for codeine (69,796), oxycodone (16,651), and tramadol (16,289). All changes were significant at $p<0.0001$. In the post-period, HCP (4,520 prescriptions/month), oxycodone (672.1), tramadol (108.3), and other (31) opioid prescriptions significantly declined each month ($p<0.0001$), except for codeine (49.5; $p=0.7588$). Similar trends were observed for dentist- and population-based prescribing rates across all opioids. In the post-period, monthly mean quantity and days' supply dispensed, and MME significantly declined across all opioids ($p<0.0001$). For HCP in 2012 compared to 2017, average quantity dispensed per prescription decreased by 11% (18.4 pills vs. 16.3), days' supply decreased by 8% (3.5 days vs. 3.2), and MME decreased by 8% (36.2 MME vs.33.4).

Conclusions: US dentists' prescribing of HCP declined after the DEA rescheduling, but may have consequently increased prescribing of other opioids, including high potency agents. Understanding the impact of this regulation is important to develop strategies to ensure safe and effective prescribing of opioids for dental pain.

3758 | Impact of pharmaceutical cost containment policy changes on the use of antidepressants in Japan

Shinobu Imai[1,2], Anna Kiyomi[1], Munetoshi Sugiura[1], Kiyohide Fushimi[3] and Karolina Andersson Sundell[4]

[1]Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan; [2]National Hospital Organization Headquarters, Tokyo, Japan; [3]Tokyo Medical and Dental University Graduate School, Tokyo, Japan; [4]University of Gothenburg, Gothenburg, Sweden

Background: In the last two decades, many countries have been affected by the global financial crisis. At the same time, pharmaceutical expenditures have increased exponentially. The use of antidepressants and the associated expenses have grown in many countries, mainly because of the introduction of emerging pharmaceutical classes of antidepressants with a better risk-benefit profile compared to the conventional milder antidepressants, which require extended use for treating depression and anxiety.

Objectives: In this study, we analysed the changes in the trends of using antidepressants upon introduction of new guidelines, safety information, cost containment policies and approval of original brand drugs and generic drugs, with the overarching aim of assessing the Japanese generic drug promotion policy.

Methods: Time series analysis was performed using the seasonal autoregressive integrated moving average (ARIMA) modelling method along with the intervention analysis. Sales data of the selected drugs, including SSRIs, SNRIs and other antidepressants, from April 2002 to March 2016 were collected from IQVIA. Altogether, eight interventions were analysed, including three policy changes (P1, P2 and P3), three published guidelines (GL1, GL2 and GL3), and two safety information (SI1, SI2). Based on the status of the patent, we classified the drugs into three categories: drugs that are no longer protected by a patent (LP), new substances (OT), and generic drugs (GE).

Results: The use of SSRI/SNRI peaked by 2008 and reached a plateau. However, the introduction of SI1 in 2006 and SI2 in 2009 resulted in a significant downward shift in the use of SSRI/SNRI and an upward shift in other antidepressants. According to the stratification of the use of SSRI/SNRI by patent status, i.e., LP, OT, or GE, the use of LP drugs started to decline since 2008; instead, the use of OT drugs started to increase since 2012. When milnacipran, the first generic drug of SSRI/SNRI was introduced in 2008, there were a significant downward shift in the use of LP drugs. However, the share of GE was lower than the share of OT by the end of study period.

Conclusions: We describe the trends in usage of antidepressants during this decade. Introduction of safety information had a negative impact on the use of SSRI/SNRI, which was substituted by other antidepressants. We also described the situation in which there was a switch from the use of LP to OT drugs.

3823 | Establish a model for mapping Chinese indication with ICD-10-CM in Taiwan: Using antipsychotics as examples

Chien Chou Su[1,2], Ching-Lan Cheng[1,2,3,4], Yi-Wei Wu[3] and Yea-Huei Kao Yang[2,3,4]

[1]National Cheng Kung University Hospital, Tainan, Taiwan; [2]Health Outcome Research Center, National Cheng Kung University, Tainan,

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Taiwan; [3]Institute of Clinical Pharmacy and Pharmaceutical Sciences, National Cheng Kung University, Tainan, Taiwan; [4]School of Pharmacy, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background: In Taiwan, the labelled indications of pharmaceutical products are approved in Chinese language by Taiwan Food and Drug Administration (TFDA), which are known to be described variably for one single active pharmaceutical ingredient. Meanwhile, the National Health Insurance (NHI) reimbursement scheme of pharmaceutical preparations is implemented based on the labelled indications by TFDA. However, the claims of pharmaceutical reimbursement are required to submit using the International Classification of Disease (ICD). Therefore, when evaluation on the prescribing compliance with reimbursement scheme is needed, a mapping system of Chinese indications with ICD codes should be established in advance.

Objectives: To establish a mapping system between indication and ICD-10-CM for TFDA approved antipsychotics (APs), and evaluate the validity of ICD-10-CM mapping with indication by reviewing electronic medical records.

Methods: *Design and setting*: The mapping process was performed by dictionary-based and keywords matching method. The dictionary-based method was to define the same concept between Chinese indications and English medical terminologies by researchers in advance, and converted the Chinese indications into English indications. These converted indications were linked to SNOMED CT system by keywords matching, and further mapped with ICD-10-CM. *Statistical analysis*: we selected risperidone as the index drug for examining the validity of ICD-10-CM mapping of indication. Sensitivity and positive predictive value (PPV) for ICD-10-CM were evaluated by reviewing electronic medical records in a medical center.

Results: The mapping rate was 99.9%. In this mapping system, there were 784 pharmaceutical licenses approved by TDFA. Among the matched ICD-10 CM, there were 65.5% belonged to mental and behavior disorders, 1.6% diseases of the nervous system, 7.7% factors influencing health status and contact with health services, 6.5% symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified, and the others was 18.7%. The rate of this mapping system, the sensitivity and PPV of risperidone prescriptions and indications in the electronic medical records were 94.6% and 80.8%, respectively.

Conclusions: The mapping strategy for linking Chinese indications to ICD-10-CM via SNOMED CT can be employed for the other pharmaceutical products, which may support utilization evaluation of the reimbursement scheme in Taiwan NHI.

3911 | Serious adverse events with high-cost drugs accessed through litigation in Brazil

Ricardo Eccard da Silva[1], Elisângela da Costa Lima[2], Maria Rita C.G. Novaes[3] and Claudia Garcia Serpa Osorio-de-Castro, 21041-210[4]

[1]Brazilian Health Surveillance Agency (Anvisa), Brasília, Brazil; [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]University of Brasília, Brasília, Brazil; [4]Sergio Arouca National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

Background: Serious and/or rare conditions with high social impact and risk of death are usually treated with high-cost drugs/medicines either recently brought to market or still undergoing trials for later licensing. Brazilian patients have legal right to access unlicensed drugs undergoing clinical research, if there is evidence of efficacy and safety.

Objectives: This study investigated the occurrence of serious adverse events related to very high-cost medicines from clinical studies and obtained by patients though health litigation.

Methods: A descriptive study using secondary data investigated unlicensed medicines obtained through lawsuits from 2010 to 2017, costing more than 1 million Brazilian reais (BRL), adjusted by the Brazilian Consumer Index to July 2017. Data sources were the Brazilian Health Surveillance Agency Registry (DATAVISA) and Adverse Events in Clinical Studies (NotivisaEC) Databases. Medicines were categorized by the Anatomical Therapeutic Chemical classification to level 03 and events by the WHO Adverse Drug Reaction Terminology. The study received ethical approval by the UnB IRB.

Results: In the period, 812 drugs in clinical studies were obtained thorough litigation. 44 (5.4%) were related to 1248 serious events. Total Brazilian Government expenditure was 3.2 billion BRL. Class L04A (n=7) presented greater expenditures (over 1.8 billion BRL). 861 (69%) took place in clinical trials, 250 (20%) in expanded access programs and 100 (8%) in compassionate use programs. 37 of all serious events (6%) were associated with post-trial drug provision. 196 deaths occurred and L01X was the most involved category (49.5%). Most other serious events (n=419) and aftereffects (n=42) were related to L01X.

Conclusions: Very high-cost drugs paid for by the government and obtained through health litigation were related to deaths and serious adverse events in Brazil.

3944 | Citizenship status and the prevalence, treatment, and control of cardiovascular disease risk factors in United States, 2011-2016

Jenny S. Guadamuz[1], Ramon Durazo-Arvizu[2], Martha L. Daviglus[1], Gregory S. Calip[1], Edith A. Nutescu[1] and Dima M. Qato[1]

[1]University of Illinois at Chicago, Chicago, IL; [2]Loyola University Chicago, Chicago, IL

Background: The adult immigrant population has doubled from approximately 19 million in 1990 to 42 million in 2017. However, noncitizens encounter significant barriers to healthcare access and disproportionately face structural factors (e.g., poverty and residence in underserved communities) that adversely impact health. Therefore, citizenship status may contribute to disparities in cardiovascular disease (CVD) and its risk factors.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To estimate the prevalence, treatment, and control of high cholesterol, hypertension, and diabetes by citizenship status.

Methods: Analyses of the National Health and Nutrition Examination Survey (2011-2012 to 2015-2016), including 16,986 adults (≥20 years). Citizenship status was categorized as US-born citizens, foreign-born citizens, or noncitizens. CVD risk factor prevalence (age-standardized), treatment, and control were defined per national guidelines and determined using serum/examination values and prescription-medication inventories.

Results: Fifty-five percent (54.6%) of US adults had high cholesterol (41.7%), hypertension (33.7%), or diabetes (13.2%); however, limited differences were observed across citizenship status. Noncitizens had considerably lower treatment rates of high cholesterol (16.4% vs. 45.5% and 43.3%), hypertension (60.3% vs. 81.1% and 79.6%), and diabetes (51.2% vs. 69.5% and 66.6%) than US-born and foreign-born citizens (all $P<.001$). These treatment disparities were consistent across racial/ethnic groups. Noncitizens were more likely to be uninsured or lack a usual source of care (52.2% and 34.5%) than US-born (13.6% and 14.3%) and foreign-born citizens (16.2% and 14.6%) (all $P<.001$). Therefore, adjusting for healthcare access characteristics attenuated treatment disparities based on citizenship status. Among adults treated for CVD risk factors, there were no significant differences across citizenship status in the control of high cholesterol (38.1%) and hypertension (71.1%), but diabetes control rates were lower among noncitizens (35.3%) than among US-born (51.2%) and foreign-born citizens (46.9%) ($P<.001$).

Conclusions: Efforts to prevent CVD, the leading cause of death among immigrants, should address the undertreatment of high cholesterol, hypertension, and diabetes by ensuring access to healthcare among noncitizens.

3950 | Impact of branded generics on the price of anti-dementia products in South Africa

Ilse Truter

Nelson Mandela University, Port Elizabeth, South Africa

Background: The Single Exit Price (SEP) for medicines was introduced in South Africa in 2004 with the aim to promote the transparent pricing of medicines. The SEP consists of the manufacturer price, the logistics fee and value added tax (15%), but excludes the dispensing fee. The SEP is periodically reviewed. In addition, generic substitution is compulsory in South Africa in an attempt to lower medicine prices.

Objectives: The aim was to use the SEP, which was introduced to standardise the pricing of medicines in South Africa, to analyse price differences of anti-dementia products.

Methods: The SEPs of four anti-dementia products in the Anatomical Therapeutic Chemical (ATC) group N06D on the South African market were extracted from the Database of Medicine Prices as on 22 January 2020. The Defined Daily Dose (DDD) was used as the standard dose, where possible, for comparative purposes.

Results: Six trade name products of memantine were available on the South African market in January 2020 (one originator and five branded generics) in one dosage strength (10 mg). The DDD of memantine is 20 mg. The price of the originator was R29.85/DDD, compared to an average price of R9.20/DDD for the branded generics (the price of the least expensive branded generic was R8.48/DDD). The film-coated branded generic tablets were slightly more expensive (R9.26/DDD) compared to the normal tablet (R9.11/DDD). Fourteen trade name products for donepezil 5 mg were available. The SEP for the originator was R25.65, compared to an average SEP of R10.99 for the 5 mg tablet (seven branded generics) and R9.81 for the 5 mg film-coated branded generic tablets (six branded generics). The price of the 10 mg originator tablet was R27.42, compared to an average of R11.44 for the 10 mg tablet (six branded generics) and R10.03 for the 10 mg film-coated tablet (seven branded generics). The price per DDD for the branded generics was on average 60% of the price per DDD of the originator (R38.47). Galantamine only had one branded generic, which was on average 60% of the price of the originator for the 8 mg, 16 mg and 24 mg tablets. Rivastigmine was only available as an originator tablet in a dosage strength of 3 mg (the price per DDD (9 mg) was R77.33/DDD.

Conclusions: Despite efforts to standardise and make medicine prices transparent in South Africa, there are still huge price differences, and recently many new branded generics became available on the market. The question can be asked whether prescribing according to active ingredients (INN prescribing) would not have been a better option in a country with a resource-constrained health care system, instead of the introduction of multiple branded generics.

3986 | Unblocking the barriers of access to direct-acting antiviral-based hepatitis C treatment in China: Lessons learnt from Tianjin City

Peiwen Zhang[1], Ran Guo[1], Jun Lian[1], Mengjia Zhi[1], Chengzhen Lu[2], Weishen Wu[3], Lihong Wang[4], Polin Chan[5], Zhongdan Chen[6], Jing Sun[1] and Yuanli Liu[1]

[1]Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [2]Tianjin No 2 People's Hospital, Tianjin, China; [3]Tianjin Center for Disease Control and Prevention, Tianjin, China; [4]Tianjin Healthcare Security Administration and Settlement Center, Tianjin, China; [5]HIV, Hepatitis and STI Unit, Division of Communicable Diseases, World Health Organization, Manila, Philippines; [6]Hepatitis/TB/HIV/STI, World Health Organization, Office of the WHO Representative in China, Beijing, China

Background: The high price is a critical barrier of access to new therapies of direct-acting antiviral (DAA) for hepatitis C for both the patients and the society. Many countries continue to face the challenge of financing such expensive medicines. Such examples include both high-income and middle-income countries. Existing evidence about the efforts of China to address this challenge is limited. To our

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

knowledge, this is the first detailed description of a novel financing model and comprehensive analysis of its impact on patient financial burden of hepatitis C treatment in China.

Objectives: To examine the evolution of approaches to navigating patients barriers of access to DAAs based treatment of hepatitis C in Tianjin city, China.

Methods: Review of publicly available literature, including published and grey literature. Conduct on-site data extraction and critical informant interview. The patient financial burden of hepatitis C treatment was analyzed. The financial burden of hepatitis C patients with different treatment models and health insurance financing models was measured by calculating the number of annual income to cover patient out-of-pocket (OOP) expenditure for the standard treatment course accordingly.

Results: Tianjin is the first area to pilot a capitated provider payment program for the treatment of hepatitis C. Through which, the retirees, employees and residents spend 0.7, 1.0 and 5.6-6.8 months of their salary and disposable income for the treatment respectively, the financial burden of patients were much relieved. By the end of March 2019, the first-year pilot program had 876 hepatitis C patients registered the new insurance coverage and treated in Tianjin.

Conclusions: The study showed that even in the developing country, the financial barriers of access to new hepatitis C treatment for patients could be unblocked with government commitment and novel financing models. International experiences demonstrated that centralized bulk procurement is a good leverage for price negotiation, primarily when using innovative payment approaches. To re-produce the initial success of Tianjin, continued efforts are needed for stronger strategic price negotiation, preferably at central level. The case of Tianjin brings implications to the other areas of China and even other developing countries that, government commitment, novel financing model and pooled procurement are critical elements of stronger purchasing power and better secure of treatment.

4062 | Medication calculation errors with moderate, severe and fatal patient outcomes: Findings from the Norwegian incident reporting system

Alma Mulac[1], Katja Taxis[2], Ellen Hagesæther[3] and Anne Gerd Granas[1]
[1]*University of Oslo, Oslo, Norway*; [2]*University of Groningen, Groningen, Netherlands*; [3]*Oslo Metropolitan University, Oslo, Norway*

Background: In 2016 and 2017, almost 40% of medication-related safety incidents reported from Norwegian hospitals were due to wrong dose errors. Dosage errors caused by miscalculations are of special interest, as there is currently little understanding of why these errors happen.

Objectives: By extracting all calculation errors with moderate, severe and fatal patient outcomes, this study examines the types of errors and their causes.

Methods: We retrospectively evaluated 3,372 medication-related incident reports submitted to Norwegian Incident Reporting System over a 2-year period for reports describing calculation errors. Medication errors were reported from 64 Norwegian hospitals in 2016, and 55 hospitals in 2017. Incident reports consisted of categorical data (e.g., patient age, incident date, day of the week) and free-text data (incident and causes description, patient consequences, prevention measures, and caseworker's comments). We selected calculation errors associated with moderate harm, severe harm and death. Errors associated with no or mild patient harm were excluded. The data were classified according to the NCC MERP Index for Categorizing Medication Errors and analyzed in SPSS. The main outcome measures were administration route, drugs and drug classes involved, calculation error enablers, mechanisms, and contributing causes.

Results: In total, 68 calculation errors with moderate, severe or fatal patient outcomes were analyzed. 30 % of miscalculations were due to conceptual errors, 26 % due to math errors and 26 % were 10- or 100-fold overdosages. Morphine was the most frequently reported medication related to calculation errors. Opioids, IV-solutions, cardiac and antibacterial therapy were the most frequently reported drug classes. The major contributing factors were procedures not adhered to (38%) and lack of double-checks. A knowledge deficit was detected in 59% of the cases. Majority of errors were reported by nurses (49%) and physicians (24%). Children (0-4 years) and elderly (75-79 years) were most at risk for calculation errors.

Conclusions: Calculation errors causing moderate, severe and fatal patient harm occurred mostly due to a lack of conceptual understanding of numbers, fractions and measurements/units. The preparation of injectable drugs should be given particular attention to prevent calculation errors and patient harm.

4209 | Utilization and expenses of traditional Chinese patent medicines in cancer treatment: A retrospective study on outpatients' prescriptions

Erdan Luo, Tianqi Zhang and Ying Bian
University of Macau, Macao, Macao

Background: Traditional Chinese Patent medicines (TCPMs) were increasingly used as a complementary treatment for cancer in China, while studies about the expenses of anticancer TCPMs were limited.

Objectives: To figure out the characteristics of utilization and expenses of TCPMs in cancer treatment.

Methods: Outpatients' prescriptions were collected from traditional Chinese medicine department of a large-scale cancer center in south China in 2017. The frequencies and rates of prescribing TCPMs were measured, and reimbursed expenses were analyzed based on China's National Basic Medical Insurance Drug Catalog (NBMIDC).

Results: A total of 23673 prescriptions with TCPMs were collected among outpatients diagnosed with cancer, mainly including nasopharynx, breast, lung, liver, cervix uteri, colorectal and stomach cancer. There were altogether 81 kinds of TCPMs used in cancer treatment. The most common prescribed drug was Lingzhibaozi, accounting 17.97% of all the anticancer TCPMs, followed by Fulingduotang (11.73%), Huazhenghuisheng (10.02%), Huaier (9.84%), Fufangzaogong (4.68%),

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Fufangbanmao (4.57%) and Anduolin (4.46%). With the instructions of immunomodulating for cancer patients, the prescribing rates of Lingzhibaozi and Fulingduotang were both accounted 10% to 40% in most cancers. Fufangbanmao was prescribed mostly in thyroid (37.94%), laryngeal (29.77%), and oral cancer (24.44%). Anduolin was prescribed mostly in ovary (17.74%) and endometrial cancer (17.86%). The average expense of TCPMs was 1084.21 RMB per prescription, which was much higher than that of Chinese herbal medicines. Noticeably, the overall ratio of self-paid TCPMs expenses accounted for 62.94%. The two top used drugs, Lingzhibaozi and Fulingduotang, which cost 1365.48 and 1244.09 RMB per patient in average, were both at patients' own expenses. While the expenses were partially covered for Fufangbanmao, Huazhenghuisheng, Huaier and Anduolin, whose self-paid ratios were depended on the reimbursement regulations in NBMIDC and types of patients' insurance.

Conclusions: The utilization of TCPMs varied in different cancers. Lingzhibaozi and Fulingduotang were widely prescribed in most cancers, while the usage of Fufangbanmao and Anduolin concentrated on head and neck cancer, and gynecologic cancer respectively. The overall expenses and self-paid ratios of anticancer TCPMs were both high. Though NBMIDC was controlling the use of TCMPs by reimbursement regulations, it is noteworthy to monitor the overuse of self-paid TCPMs to prevent the potential economic burden in cancer treatment.

4254 | Real world data to identify target population for new CAR-T therapies

Valeria Belleudi[1], Francesco Trotta[2], Filomena Fortinguerra[2], Francesca Romana Poggi[1], Odoardo Olimpieri[2], Enrica Santelli[1], Ilaria Cozzi[1], Paola Michelozzi[1] and Antonio Addis[1]

[1]Lazio Regional Health Service, Rome, Italy; [2]Italian Medicines Agency-AIFA, Rome, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive lymphoma often refractory to currently available treatments (immuno-chemotherapy/cell-stem-transplantation-ASCT). Recently, have been approved new cell therapies for patients failing two conventional treatments, CAR-T (Chimeric-Antigen-Receptor-T-cell), committing payers in planning and implementing their use.

Objectives: To define, using Real World Data (RWD), a reproducible procedure that allows estimation of the target population for CAR-T therapy.

Methods: Through the integration of electronic healthcare data (EHD), we identified patients with an incident diagnosis of non-Hodgkin's Lymphoma (NHL) during 2010-2015, resident in Lazio, aged≥ 20 years. The cases with DLBCL were followed tacking into account pathological anatomy (PA) report, up to 3 years. To be defined relapsing after two treatment lines (R2), patients must have had new chemotherapy and/or NHL hospitalization after ASCT or at the end of the second chemotherapy. R2-rate was extended to the population without PA.

Results: NLH incident patients were 7,384, 68% of which with PA record and, 29% of these had DLBCL codes. Patients who relapsed after two treatment lines were 47 (39%) in the subgroup of patients with transplant and 138 (41%) in that with second chemotherapy treatment. Patients in the two subgroups were very different in terms of age and comorbidity. Applying R2-rate (13.7%) to the DLBCL incident case, we estimated 45 patients eligible for CAR-T.

Conclusions: This study shows how RWD allows estimation of a target population with new advanced therapies. This approach is rigorous, transparent and verifiable over time with respect to the individual opinions of experts.

4394 | The rise and fall of prescription fentanyl

Shelley A. Jazowski[1], Stephen W. Patrick[2] and Stacie B. Dusetzina[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Vanderbilt University School of Medicine, Nashville, TN

Background: The United States Department of Justice and state attorneys general have increasingly scrutinized the role of pharmaceutical marketing practices in the creation and spread of the opioid epidemic. Following accusations of misleading promotion regarding prescription fentanyl's safety and appropriate use, the manufacturer of one such product (Subsys) agreed to multi-million dollar settlements in 2015.

Objectives: To evaluate the association between legal settlements and changes in the promotion and use of Subsys and other transmucosal immediate-release fentanyl (TIRF) products.

Methods: We used general payments files from the Centers for Medicare and Medicaid Services Open Payments Database and Medicare Part D Prescriber Public Use files from 2013-2017 to identify promotional (non-research) payments and prescription fills (≥11) for TIRF products: Subys (fentanyl sublingual spray), Fentora (fentanyl buccal tablet), Abstral (fentanyl sublingual tablet) and Lazanda (fentanyl nasal spray). Data for Fentora, Abstral and Lazanda were combined and analyzed separately. We used segmented regression to evaluate the association between legal settlements and quarterly promotional spending and descriptive statistics to assess annual utilization trends.

Results: Promotional spending on Subys increased $206,074 per quarter, reaching over $2.5 million in payments in Q2-2015. Immediately following legal settlements, payments abruptly declined by $1,773,576 million ($p<0.0001$). Promotional spending continued to decline each quarter, with payments equaling $136,647 in Q4-2017; a 95% decrease from the quarter preceding legal settlements. Similar trends were observed for other TIRF products.

Prescription fills for Subsys more than tripled between 2013 (4,034) and 2015 (12,667), whereas claims for other TIRF products decreased 6% to 2,455 fills in 2015. Use of Subsys declined by 46% in 2016 and an additional 55% in 2017. Similarly, prescription fills for other TIRF products decreased 5% and 29% in 2016 and 2017, respectively.

Conclusions: Promotional payments significantly decreased for TIRF products, indicating that legal settlements modified the promotional practices of Subsys' manufacturer and may have indirectly changed the marketing of other TIRF products. We also observed decreases in Subsys utilization in 2016 and 2017 perhaps suggesting that prescribers responded to promotional changes, legal concerns or both.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4424 | Development and testing of a digital observational tool to monitor bar code medication administration

Alma Mulac[1], Rune Kristiansen[2], Synne Margrethe Nielsen[1], Yvonne Andersson[3], Sandra Rut Eikeland[4], Katja Taxis[5], Ellen Hagesæther[6] and Anne Gerd Granas[1]

[1]*University of Oslo, Oslo, Norway*; [2]*Hospital Østfold Kalnes, Sarpsborg, Norway*; [3]*Hospital Pharmacies Enterprise South Eastern Norway, Oslo, Norway*; [4]*Hospital Pharmacies Enterprise South Eastern Norway, Sarpsborg, Norway*; [5]*University of Groningen, Groningen, Netherlands*; [6]*Oslo Metropolitan University, Oslo, Norway*

Background: Bar Code Medication Administration (BCMA) technology, i.e., scanning barcodes on medicines and patients' wristbands, has the potential to reduce medication administration errors, but are sometimes used incorrectly due to poor implementation and technology limitations. BCMA technology, however, affects workflow and changes the way nurses interact with patients and colleagues. Consequently, unsafe acts such as routine violations of procedures, skill-based errors or interruptions may occur. Creative workarounds are common, and unsafe practice still exists. Additionally, there is a lack of standardized methodology for measuring the implementation grade of the technology and for measuring administration errors in BCMA.

Objectives: Our aim was to develop and test a digital observational tool to collect real-world data on how BCMA technology is used in a hospital setting. The objectives were to test the digital tool while observing medication administration and get a better insight in (un) safe practices and medication administration errors.

Methods: We developed a digital online registration tool. The categories we wanted to record during observations were discussed, tested, and evaluated in a pilot in a hospital setting. This involved the themes: the use of BCMA, unsafe practices during medication administration, the errors of preparation or labeling in the trolley, information on scanned /overrides of medications, technological discrepancies during observation, the use of inpatients private medications, medication errors and field notes. The data was collected on handheld tablets.

Results: Two researchers observed nurses for 7 days, at two medical wards, as they administered medications to 30 patients. We found that the tool captured unsafe practices and errors, and provided detailed and structured data on the use of BCMA. We performed a thorough evaluation with 8 inter-professional panel-members, and extracted the most suitable categories, with the focus on the processes supporting BCMA, and excluded categories related to details of the therapy, such as drug, dose, strength, indications, and interruptions. To accommodate data registration during observation, most questions were designed as drop-down lists. In addition, a free text option was available for registering qualitative observations.

Conclusions: Our digital observational tool was successful in recording how nurses use BCMA. The tool can be used to capture technological challenges with the system, as well as documenting medication administration errors, workarounds, and violations of procedures.

4454 | Accelerated vs regular approval, differences in study characteristics of lung cancer treatments approved by the US Food and Drug Administration

Tatiane Ribeiro[1], Lewis Buss[1], Sanni Ali[2,3] and Moacyr Nobre[1,4]

[1]*Department of Preventive Medicine, Faculty of Medicine, University of São Paulo, Sao Paulo, Brazil*; [2]*Faculty of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom*; [3]*Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*; [4]*Clinical Epidemiology and Research Support Team, São Paulo Heart Institute (InCor), Sao Paulo, Brazil*

Background: Lung cancer is the leading cause of cancer death globally. The accelerated pathway is a program used for faster drug approval by the US Food and Drug Administration (FDA) and it allows approval based on surrogate endpoints.

Objectives: To assess differences between accelerated vs regular pathway approvals made by the FDA for lung cancer treatment, from 2006 to 2018, in terms of study design, sample size, effect size and outcome measures.

Methods: Two independent researchers reviewed the @DrugsFDA in the FDA's online bulletin that includes all approvals for lung cancer drugs. The data collected included: study type (RCT or single-arm), sample size (<200 vs ≥200 patients), the primary outcome (overall survival or surrogate endpoint) and effect size (large vs not large; Risk ratio, RR ≥ 2 was considered large). Accelerated pathway approvals were identified on the FDA website. Study characteristics were compared between accelerated and regular approvals. The absolute number differences were presented and a 2-sided P value .05 was used to assess statistical significance by Fisher's exact test.

Results: From 2006 to 2018, the FDA approved 31 new drugs and supplemental indications for lung cancer, totaling 37 studies: 13 via accelerated and 24 via the regular pathway. Proportionally more approvals via the accelerated pathway were based on single-arm trials (85% vs 21% p<0.001) and small sample sizes (69% vs 29% p=0.036). Surrogate outcomes were more frequent among accelerated approvals (92% vs 58% p=0.057). Large effect size (RR ≥ 2) was not different between the pathways (38% vs 25% p=0.27).

Conclusions: Single-arms, small sample size and surrogate endpoints are associated with low quality of evidence and we find that it's more prevalent in the accelerated pathway for lung cancer approval. However, a larger effect size was not observed in the accelerated pathway approvals.

4490 | Association of formulary exclusions and restrictions for opioid alternatives with opioid prescribing among medicare beneficiaries

Tanvi Rao[1], Zippora Kiptanui[2], Paul Dowell[2], Corey Triebwasser[3], G. Caleb Alexander[4] and Ilene Harris[2]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. [1]IMPAQ International, LLC, Washington, DC; [2]IMPAQ International, LLC, Columbia, MD; [3]IMPAQ International, LLC, Wellesley, MA; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: While there are many pharmacologic alternatives to opioids, it is unclear whether the structure of Medicare Part D formularies discourages their use.

Objectives: (1) To quantify the coverage of opioid alternatives and the prevalence of prior authorization [PA], step therapy [ST], quantity limits [QL] and tier placement for these drugs; and (2) to test whether these formulary exclusions and restrictions are associated with increased opioid prescribing to older adults, at the county level.

Methods: Design, Setting, and Participants: County-fixed effect models estimated using a panel of U.S. counties over the 50 U.S. states and the District of Columbia over calendar years 2015 and 2016. The sample included 2721 counties in 2015 and 2671 counties in 2016 with sufficient data on Medicare Part D formulary design and opioid prescribing. **Main outcomes and measures:** County-level opioid prescribing rate (number of opioid claims divided by the number of overall claims) and counts of excluded opioid-alternatives and opioid-alternatives with PA/ST/QL and high-tier placements.

Results: We examined 30 non-opioid analgesics across over 28,000 Medicare plans. On average, Medicare plans did not cover 7% of these drugs (interquartile range [IQR] 10%). Among covered non-opioids PA and ST were uncommon, with fewer than 5% impacted by PA and 0% by ST. On the other hand, 13% of covered non-opioids had quantity limits (IQR 10%) and 22% were in high-cost tiers (IQR 38%). Increases in the number of non-opioids excluded on Medicare plans in a county were associated with increased opioid prescribing (effect size relative to mean, 2.2-3.7%; $P<0.01$). Conversely, increases in the number of opioids not covered on Medicare plans in a county was found to be associated with decreased opioid prescribing (effect size relative to mean, 0.8-1.5%; $P<0.02$). None of the utilization management strategies (PA/ST/QL) examined, nor high cost tier placements of non-opioids, were statistically associated with increased opioid prescribing.

Conclusions: Restricting access to pharmacologic alternatives to opioids may contribute to increased opioid prescribing.

4563 | Triptans-utilization study for regulatory action on medication-overuse headache: Using nation-wide claim database in Japan

Sono Sawada, Haruka Shida, Kazuhiro Kajiyama, Mikiko Kubo, Yoko Takaashi, Chieko Ishiguro and Yoshiaki Uyama
Pharmaceuticals and Medical Devices Agency (PMDA), Tokyo, Japan

Background: Under the universal care service in Japan, almost all medical claims submitted electronically are aggregated as the National Database (NDB). As of March, 2018, the NDB covered more than 95% of claims. Using this database, the Pharmaceutical and medical device agency (PMDA), the Japanese regulatory agency, has been conducting several drug-utilization studies for the purpose of drug-safety assessment. One of these studies will be reported here. There was the concern on triptans, a class of migraine medication, overuse-induced headache from Japanese and foreign spontaneous reports, however, no data were available regarding the situation in clinical practice in Japan.

Objectives: To identify the total number of patients who were prescribed triptans from 2010/8 to 2016/3 in Japan and the proportion of patients suspected of overusing the medication among them.

Methods: Drug claims obtained from hospitals, clinics, dental clinics, and outpatient pharmacies during the period of 2010/8 to 2016/3 were used as a data source. At first, we identified the total number of triptan-prescribed patients and the number of patients who were suspected of triptan-overuse and calculated the proportion of them among the total patients. A case of "possible addicts" was defined as a patient with at least one of the following criteria; 1) for four and more continuous months, the total amount of prescribed triptans in a single month exceeded 10 times more than the maximum single dose. 2) The total amount of prescribed triptans in a certain month exceeded 10 times more than the maximum single dose multiplied by X months ($X \geqq 4$) and the next prescription was recorded within X months. We also defined "probable addicts" by replacing the term "the maximum single dose" with "the maximum daily dose". These definitions were established on the basis of the definition of "Triptan-overuse headache" in the International Classification of Headache Disorders 3rd edition(ICHD-3).

Results: A total of 2,078,556 patients with triptans prescription were included for analysis in this study. Of those, 102,871 (4.95%) and 16,426 (0.79%) patients were identified as "possible addicts" and "probable addicts", respectively.

Conclusions: Based on the results in this study as well as the situation in foreign counties, the MHLW, the Ministry of Health, Labour and Welfare, and PMDA have decided to require the marketing authorization holder of triptans products to put the important precautions about medication-overuse headache on their package inserts.

4595 | Hormone replacement therapy (HRT) and risk of breast cancer: Nested case-control studies using QResearch and clinical practice research datalink (CPRD)

Yana Vinogradova[1], Carol Coupland[1] and Julia Hippisley-Cox[2]
[1]University of Nottingham, Nottingham, United Kingdom; [2]University of Oxford, Oxford, United Kingdom

Background: HRT can relieve often life-changing menopausal symptoms for many women, but the Women's Health Initiative (WHI) and many smaller studies reported increased breast cancer risk associated with its use. Most studies were, however, underpowered to investigate different HRT preparations and the WHI included only two. A recent Lancet meta-analysis pooled results from numerous, rather heterogeneous studies, and has reported higher than expected risks.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To quantify breast cancer risks associated with different HRT treatments.

Methods: Two separate studies used the QResearch and CPRD primary care databases containing UK general practice records, representative of the general population. Overall between 1998 and 2018, 98,611 women aged 50 to 79 had a primary breast cancer diagnosis. Each case was matched by birth year and practice to up to 5 controls, alive and registered at the time of case diagnosis (index date). Exposure to different HRT treatments was based on prescriptions other than in the year before the index date. Duration of use (long-term, ≥ 5 years; short-term, 1 to <5 years) and recency of use (current, <5 years before the index date; past, ≥ 5 years) were both investigated. Conditional logistic regression was used to calculate odds ratios adjusted for smoking, ethnicity, body-mass index and co-morbidities associated with increased risk of breast cancer or use of HRT. Separate analyses were run for each database and the results combined using meta-analysis techniques.

Results: Overall, 33,709 (34%) cases and 134,391 (31%) controls had used HRT. Compared to no use, long-term current use was associated with increased risks of breast cancer for oestrogen-only therapy (odds ratio 1.15, 95% confidence interval 1.09 to 1.21) and oestrogen-progestogen therapy (1.79, 1.73 to 1.85). For combined progestogens, increased risk was highest for norethisterone (1.88, 1.79 to 1.99) and lowest for dydrogesterone (1.24, 1.03 to 1.48). Past oestrogen-only use and past short-term oestrogen-progestogen use were not associated with increased risk. However, the risk associated with past long-term oestrogen-progestogen use remained increased (1.16, 1.11 to 1.21).

Conclusions: This observational study covering all common HRT treatments in the UK is the largest consistent study done and provides reliable population-based risk estimates. While echoing the pattern of the Lancet meta-analysis findings, our estimates appear lower and more in line with earlier studies. They should assist any patient and their doctor when selecting appropriate therapy.

4734 | Comparing opioid regulations globally across regions with different levels of opioid utilisation

Teng-Chou Chen[1], Björn Wettermark[2], Douglas Steinke[1], Gillian Caughey[3], Mina Tadrous[4], Veronika Wirtz[5] and Li-Chia Chen[1]

[1]Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom; [2]Department of Pharmacy, Uppsala University, Uppsala, Sweden; [3]Registry of Senior Australians, South Australian Health and Medical Research Institute and Division of Health Sciences, University of South Australia, Adelaide, Australia; [4]Women's College Hospital, Toronto, ON, Canada; [5]School of Public Health, Boston University, Boston, MA

Background: The enactment of policy to control opioid prescribing has been associated with decreased opioid utilisation and related-harms. However, strictly limited access to opioids can potentially lead to unmet needs of pain management.

Objectives: This study aimed to identify the variation in opioid policies across global jurisdictions with different levels of opioid utilisation to explore the feasibility of conducting a cross-national comparison (CNC) study investigating the impacts of policies on opioid-related issues.

Methods: A cross-sectional survey included participants by purposeful sampling from March to November 2018. Experts with interests in CNC studies comparing opioid utilisation were invited to participate at the Drug Utilisation Research Special Interest Group (SIG) of the International Society for Pharmacoepidemiology in 2017. Information related to controlled drug schedules, regulations and the most commonly used opioid in each region were collected by a face-validated electronic survey. Regions were defined as geographic areas with unique regulations and were categorised according to their level of opioid consumption using the Adequacy of Consumption Measure. Descriptive statistics were applied to present the frequency of answers for the individual items included in the survey.

Results: Overall, 35 responses from 22 regions were received, and 5, 8 and 9 regions had opioid consumption categorised as more than adequate, moderately adequate or less than moderate, respectively. All 22 regions had control substance regulations, with the majority of opioids listed as controlled substances, but 11 regions did not list tramadol as a controlled substance. Most regions restricted the access to opioids by limiting the amount and duration of a prescription (n=10) or authorising certain pharmacies to supply prescription opioids (n=5). Among the 5 regions with more than adequate opioid consumption, oxycodone or codeine with paracetamol were the most commonly used opioid preparations. In contrast, tramadol was the most commonly used opioid among the 9 regions with opioid consumption categorised as less than moderate.

Conclusions: There is a variation in national regulations regarding opioid prescribing, and regions had higher opioid consumption were tend to prescribed stronger opioids. Despite tramadol being the most commonly used opioid in regions with less opioid consumption, there was no consensus about its classification as a controlled substance. Further CNC studies should investigate the impacts of regulations on opioid prescribing.

4846 | Over 2000 seniors initiate second-line osteoporosis pharmacotherapy monthly in Ontario - Impact of drug policy change and call for research

Natalia Konstantelos, Nancy He, Kaley N. Hayes and Suzanne M. Cadarette

University of Toronto, Toronto, ON, Canada

Background: Osteoporosis is a brittle bone disease characterized by low bone mineral density and increased fracture risk. Oral bisphosphonates are the primary drugs used to treat osteoporosis in Canada. However, not all patients tolerate oral bisphosphonates or continue to lose bone on therapy. These patients may benefit from switching to more potent second-line treatment options: annual

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

infusion of zoledronic acid or biannual denosumab injection. All residents over the age of 65 can access drugs listed on the Ontario Drug Benefit (ODB) formulary. Zoledronic acid was added to the ODB formulary in 2006 and denosumab was added in 2012, yet both were restricted to women meeting high fracture risk criteria, and special authorization was required that limited coverage in men. Coverage for both drugs broadened February 2018 to include men and women with fewer restrictions.

Objectives: To estimate the impact of the 2018 policy change on the number of seniors initiating second-line osteoporosis therapy in Ontario.

Methods: We identified Ontario residents aged 66 or more years initiating denosumab or zoledronic acid, 2016/02 - 2019/12. Interrupted time series analysis (segmented linear regression with autoregressive error models) was used to examine the impact of the policy change (2018/02) on the monthly number of new users of each therapy, accounting for seasonality, non-stationarity, and autocorrelation. Analyses were completed by sex for denosumab, yet combined for zoledronic acid due to small sample size.

Results: We identified 85,893 denosumab (mean age 79, SD=8.2; 88% women) and 1040 zoledronic acid (mean age 74, SD=6.3; 84% women) initiators during the study period. The monthly number of initiators was stable over the 2 years pre-intervention with an average of 33 men and 1,405 women starting denosumab, and 18 seniors starting zoledronic acid. A significant immediate increase in denosumab use (477% men; 21% women), and zoledronic acid (25%) occurred at the time of the policy change. The number of initiators exceeded predicted values post-policy change with a relative increase of 62% (n=40) for zoledronic acid, and 62% for denosumab (men: 177%, n=357; women: 44%, n=1959) with a post-intervention monthly average of 408 men and 1826 women and starting denosumab, and 27 starting zoledronic acid.

Conclusions: After broadening coverage, over 2000 seniors start second-line therapy monthly in Ontario. Better understanding of the characteristics of patients initiating denosumab vs. zoledronic acid as well as the relative benefits and harms of these therapies in the real-world is needed.

4883 | Impact of meningioma risk minimization campaign on cyproterone acetate use in France

Camille Morival[1], Marine Penichon[2], Clément Mathieu[2], Natapy Attoumi[1], Louis Letinier[1], Amandine Gouverneur[1], Antoine Pariente[1] and Julien Bezin[1]

[1]Bordeaux Population Health Research Center, Team Pharmacoepidemiology, UMR 1219, Inserm, University of Bordeaux, Service de Pharmacologie Médicale, Pôle de Santé Publique, CHU de Bordeaux, Bordeaux, France; [2]Bordeaux Population Health Research Center, Team Pharmacoepidemiology, UMR 1219, Inserm, University of Bordeaux, Bordeaux, France

Background: Cyproterone acetate (CA) is a synthetic progesterone derivative with anti-androgenic properties. In France, it is commonly used in hormone related disorders resulting in androgenization in the woman, and is indicated in prostate cancer and reduction of drive in sexual deviations in men; off-label use for contraception and acne has been evidenced. A risk of meningioma was reported among users of high cumulated doses of CA since 2007 which led to risk minimization campaign by French Health Authorities after 2011.

Objectives: This study aimed at describing the impact of national health policies on the use of cyproterone acetate in France.

Methods: We analysed data from the nationwide monthly drug claim database for the 01/01/2010 to 30/09/2019 time period. Monthly reimbursed amount of CA were derived from the information of refunded packages and expressed in terms of defined daily doses (DDD). Key dates of the risk minimization campaign and communication concerning the meningioma risk were identified from Health Authorities' websites. Briefly, the ain dates were : addition of meningioma as a contraindication in the SmPC in 2011; results of the national pharmacovigilance survey in March 2014; creation of the scientific committee in charge of the risk minimization campaign at the French national drug authority and results of a pharmacoepidemiology risk study in June 2018; risk communication to patients and health professionals from August to November 2018. Change point analysis was used to identify potential changes in monthly CA claims. The analysis was stratified according to the two CA dosage available in France (50mg;100mg).

Results: For 100mg CA and 50mg CA, the monthly amount of reimbursed DDD evolved from 329,640 and 706,290 DDD in January 2010 to 39,900 DDD and 152,610 DDD in September 2019, respectively. Graphically, CA 100mg decreased continuously over the study period, whereas CA 50mg decreased especially after July 2018 which correspond to the beginning of the public risk communication. The change point analysis evidences a significant 55.1% decrease starting from March 2015 in the monthly amount of reimbursed DDD for 100mg CA, and a significant 35.5% decrease starting from September 2016 for that of 50mg CA.

Conclusions: Cyproterone acetate 100mg amount of use changed following the risk signal identification. In contrast, cyproterone acetate 50mg amount of use change concomitantly to the establishment of the risk minimization campaign in France. However, change point analysis method identified earlier significant change in the use of cyproterone acetate 50mg.

4892 | Ecuador's administrative data sources for drug utilization research

Mónica Tarapues[1], Carlos Durán[2], Belén Mena[1], Patricia Granja[3], Lisiane Leal[4], Monique Elseviers[5] and Luciane Cruz[6]

[1]UCE, Quito, Ecuador; [2]Ghent University, Ghent, Belgium; [3]PUCE, Quito, Ecuador; [4]McGill University, Montreal, QC, Canada; [5]Ghent University, Ghent, Belgium; [6]University of Sorocaba, Sao Paulo, Brazil

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Health-related administrative sources of information are currently a source in pharmacoepidemiological research. Along the years, different databases have been developed to manage medical and pharmacy records that are now electronically reported with the possibility of establishing record linkage systems. However, in LA countries as Ecuador little is known about the availability of the information and its application in drug utilization research.

Objectives: The aim of this study is to outline the main characteristics of administrative data sources of Drug Utilization (DU) from Ecuador.

Methods: A network of health experts, liaising with national data providers and academic experts in Pharmacoepidemiology & DU research conducted a website search in government institutions. Researchers independently screened eligible data sources to identify public, health-related administrative data in Ecuador. From each source of information, we collected information on accessibility, coverage (national, regional, municipality, organization multi-site), data provider (public health, private sector, both), type of data sources (wholesaler, pharmacy records, electronic health records, other), setting (ambulatory, hospital, both), covered periods. Descriptive analysis was performed.

Results: The Ecuadorian Institute of Social Security and the Ministry of Health are the main public healthcare providers in Ecuador. For DU research, we identified 4 data sources, which are not publicly and conveniently accessible on line; all of them reported data from ambulatory and hospital settings, but only in 2 are possible to separate; 3 include only data from the public sector. One data source receive notifications of adverse events and technical complaints related to the use of medicinal products. Data source from the social security institute include clinical data as well as dispensing registries. The last includes the patients´ record number, gender, age, date of dispensing, name and code of the drug, the number of dispensed units and the actual price per unit.

Conclusions: Dispensing registries are the main data source of DU data in Ecuador. Transparency and public accessibility of the data is a major weakness of the Ecuadorian DU data sources. Unfortunately, current information is limited and segmented. Latin American and Ecuadorian researchers, as policy makers as well, must pressure to improve the quality and transparency of DU data.

4990 | Ondansetron in pregnancy: Patterns of usage and characteristics of patients in UK general practice

Jim Slattery Slattery[1] and Hedvig Nordeng[2]
[1]*European Medicines Agency, Amsterdam, Netherlands;* [2]*University of Oslo, Oslo, Norway*

Background: Hyperemesis gravidarum (HG) is not a labelled indication of ondansetron in the UK but Royal College of Obstetricians and Gynaecologists guidance suggests that it is safe and effective as a second line treatment for nausea and vomiting & HG in pregnancy. Recent studies from the US, where exposure is common in pregnancy (possibly 9%), have suggested a possible association of in-utero exposure to ondansetron with cardiac defects and oral cleft in the child. The potential clinical significance of these findings for the UK can be informed by measurements of ondansetron usage.

Objectives: To determine treatment patterns for ondansetron in pregnancy and to characterize the target population.

Methods: The study population consists of 717007 pregnancies that can be matched to a live birth within an IMRD-UK registered GP practice between 2005 and September 2018. In-utero exposures to ondansetron were described with respect to year of birth, dosage and timing within the pregnancy and the temporal relationship to first line anti-emetics recommended by the RCOG was examined. The characteristics of exposed mothers in terms of age, smoking, clinical diagnoses and exposures to other forms of medication were contrasted with unexposed mothers. Odds ratios were calculated for each characteristic.

Results: Prescription rates for ondansetron during pregnancy steadily increased over the study period from 0.04% in 2005 to 1.99% in 2018. First trimester exposure increased from 0.01% to 1.11% over the same period. In addition to other anti-emetics (antihistamines) and therapies to treat the sequelae of HG (Oral rehydration, vitamins and nutrients), use of ondansetron was disproportionately associated with antipsychotics (OR=13.1 compared to unexposed), antidepressants (OR=2.0), antibacterial (OR=2.0) and drugs for constipation (OR=1.9). Associated clinical events other than nausea or vomiting included gastrointestinal hemorrhage (OR=7.8), emergency hospital admission (OR=4.6) and thyrotoxicosis (OR=4.3).

Conclusions: Although UK use of ondansetron for nausea in pregnancy has increased in recent years it is not yet close to levels of use in the US. Formal etiological studies of association with birth defects in UK, and probably EU, data will face challenges due to low exposure, rare outcome events and a target treatment population with many distinctive clinical features that may require adjustment in statistical models. None-the-less, the continued increase in usage suggests that such analyses should be carried out.

5014 | Key evidence supporting prescription opioids approved by the U.S Food and Drug Administration, 1997-2018

James Heyward[1], Thomas J. Moore[2], Jennifer Chen[3], Kristin Meek[1], Peter Lurie[4] and Caleb Alexander[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Institute for Safe Medication Practices, Alexandria, VA;* [3]*Johns Hopkins School of Medicine, Baltimore, MD;* [4]*Center for Science in the Public Interest, Washington, DC*

Background: Despite increased scrutiny of U.S. Food and Drug Administration (FDA) regulation of opioids, no study has yet assessed the evidence thresholds applied to new approvals of opioid analgesics.

Objectives: (1) To characterize the quality of safety and efficacy data in New Drug Applications (NDA) for opioid analgesics approved by the FDA between 1997 and 2018.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a cross-sectional analysis of NDAs using ClinicalTrials.gov, FDA reviews and peer-reviewed publications. Patient populations of interest were acute and chronic pain patients enrolled in pivotal trials (the main trials considered for drug marketing approval) of FDA-approved opioid analgesics. We assessed key characteristics of each NDA including: number, size and duration of pivotal trials; trial control; use of enriched enrollment randomized withdrawal designs (EERW); and systematically measured outcomes from pooled safety analyses.

Results: Of 48 NDAs, most were for new dosage forms (n=25, 52.1%) or new formulations (n=9, 18.8%); only 1 (2.1%) was for a new molecular entity. Among products supported by at least one pivotal trial, eight approved acute pain products had a total of 19 Phase III trials with a median treatment duration of 2 days (interquartile range [IQR] 1, 3) enrolling a median of 329 (IQR 199-456) patients, and twenty-one opioids approved for chronic use included 28 Phase III trials with a median duration of 84 (IQR 25-84) days, enrolling a median of 298.5 (IQR 174-525) patients. Seventeen of these twenty-one opioids (81%) were approved based on EERW designs. Among the 42 NDAs subject to safety data requirements, 15 (35.7%) included pooled safety reviews that reported systematic assessment of the development of drug tolerance (including 14/33 NDAs for chronic use, 42.4%), 8 (19.0%) reported systematic assessment of study drug diversion, and 7 (16.7%) reported systematic measurement of non-medical opioid use. While all but one of 48 NDA's approved were for previously approved moieties, analysis of available NDA's for referent products yielded similar findings.

Conclusions: Between 1997 and 2018, the FDA approved opioids based on Phase III trials of short and intermediate duration, often in narrowly defined pain populations among patients able to tolerate the drug. Systematic collation of important safety outcomes was rare.

5040 | Pain management curricula within health professional schools in the United States: A landscape analysis

James Heyward[1], Beth Hogans[2], Jacob Christopher[1] and Caleb Alexander[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Johns Hopkins School of Medicine, Baltimore, MD*

Background: Given the ongoing opioid epidemic in the United States, even as chronic pain persists, pain management preparedness for health professionals is vitally important.

Objectives: To assess the current state and future of pain education in U.S. health professions schools utilizing (1) literature review; (2) appraisal of accreditation documents; and (3) conduct of key informant interviews.

Methods: A National Institute on Drug Abuse (NIDA)-commissioned study using three-pronged analyses of pain education at health professional schools in the U.S., including allopathic and osteopathic medical, nursing, physician assistant, pharmacy, and physical and occupational therapy. Our approach consisted of a formal review and synthesis of the peer-reviewed literature focusing on studies describing the content, medium, setting, and other characteristics of pain education programs in the U.S.; analysis of information presented by professional accreditation organizations, especially guidelines and competencies for programs; and in-depth key informant interviews with educational leaders in diverse health professions. We performed iterative analysis and synthesis of the information from these data-gathering approaches.

Results: Thirty-one publications were included in our review of the recent literature, most focused on medical education; five examined interprofessional education. Of the accreditation organizations contacted, half maintained information regarding curriculum standards - this information was limited to general standards for clinical preparedness, and was not sufficiently detailed for further study. Key informants included six curriculum leaders from varied health professions. Despite recommendations and guidelines, pain management preparation was inconsistent across programs, professions, specialties and disciplines. Teaching was often fragmented and bootstrapped; and competed with many other topics, barriers to implementation of coordinated curricula were prominent. We observed innovation and change, including novel programs incorporating multimodal pain-care strategies, interdisciplinary and interprofessional programming, and coordination with substance abuse training.

Conclusions: Despite considerable activity in the health professional training programs examined, barriers prevent programs from offering consistent, comprehensive, longitudinal, and high-quality pain management training. At present, accreditation standards and oversight organizations do not support critically needed improvements in pain management preparedness.

5058 | Drug use research in Peru: Is real-world data available?

Yesenia Rodríguez[1], Maribel Salas[2], Lisiane Leal[3], Monique Monique[4] and Luciane Cruz Lopes[5]

[1]*Institute of Health Technology Assessment and Research (IETSI), Lima, Peru;* [2]*Daiichi Sankyo, New Jersey, NJ;* [3]*Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, QC, Canada;* [4]*University of Ghent, Ghent, Belgium;* [5]*University of Sorocaba, São Paulo, Brazil*

Background: Drug utilization research (DUR) is being progressively demanded by health authorities and payers to assess the impact on the benefit-risk of drugs in the real-world setting. DUR is used to provide evidence-based data to inform policies and make decisions. Health System in Peru is based on Integrated Health Networks, and it is administered centrally by the Ministry of Health. No mapping has been conducted until now to describe the existing data sources for DUR in Peru.

Objectives: To map and describe data sources publicly accessible for DUR in Peru

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Experts in Peru's Health Care System and academic Pharmacoepidemiology experts were invited to ensemble a network. A manual search of data sources providing information about medication use in the website from Peruvian institutions (government, academic, private) was made. In addition, we developed a systematic review of scientific literature using PubMed and LILACs to retrieve studies or documents (Bulletin, etc.) that used such data sources in Peru. Working in pair team of reviewers independently screened eligible studies and data. The data sources collected information on accessibility, geographic granularity, sector, type, and setting. Data were analyzed in a descriptive manner.

Results: From seven data sources identified, only one was publicly available. The process for obtaining data was not clear for the other data sources. Four had national granularity; five were from the Public health system. Each data source presented different source types: health care providers and Marketing Authorization Holders. The setting of data source was both hospital and ambulatory care and most of them had less than 10 years of coverage. Two data sources have individual-level data on adverse drug reactions and prescriptions. From the systematic review developed, we found two studies, one was derivate from the National Health Care survey (ENSUSALUD 2016) and the other from the Drug Integrated System (SISMED) of the Ministry of Health of Peru

Conclusions: The National Health Care survey conducted in 2016 was the only data source available. In general, the overall context of data sources for DUR in Peru is unknown. Few studies were conducted so far and internal initiatives and partnerships with universities seem to be a good strategy to improve drug utilization research in Peru.

5118 | Data sources for health care decision making in Mexico: Challenges and strength (Mexican Working Group on DUR)

Diana Gomez[1], Svetlana Doubova[2], Anahí Dreser Mansilla[3], Juan Carlos Sanchez Salgado[4], Lucila Castro Pastrana[5], Yared Santa Ana Tellez[6], Elena Ibarra Cazares[7], Isabel Hernández Lira[8], Lisiane Leal[9], Maribel Salas[10], Monique Elseviers[11] and Luciane Cruz Lopes[12]

[1]Universidad Autonoma del Estado de Morelos, Cuernavaca, Mexico; [2]Mexican Institute of Social Security, Mexico City, Mexico; [3]Instituto Nacional de Salud Pública, Cuernavaca, Mexico; [4]Immunology and Advanced Science Institute, Mexico City, Mexico; [5]Universidad de las Américas, Puebla, Mexico; [6]Utrecht University, Utrecht, Netherlands; [7]Universidad Autónoma Metropolitana, Mexico City, Mexico; [8]National Cancer Institute, Mexico City, Mexico; [9]McGill University, Montreal, QC, Canada; [10]University of Pennsylvania, Philadelphia, PA; [11]Ghent University, Belgium, Belgium; [12]University of Sorocaba, São Paulo, Brazil

Background: Access to consistent and validated information on drug utilization is crucial to inform decision making, both at the national policy level as well as in health care settings. However, this information is not always available or appropriate. Research on reliable data sources, and the development of a national inventory of such data sources contributes to prompt public health decisions.

Objectives: The aim of this descriptive study was to develop an inventory of the data sources for drug utilization research (DUR) in Mexico, highlighting databases potential strengths and limitations for decision-making

Methods: A Mexican working group on drug DUR that included health professionals, national data providers, and academic experts in the research fields of pharmacoepidemiology, health economics, and health systems research, research conducted an internet search of the institutional and governmental Mexican websites. The collected information from various data sources included accessibility, geographic granularity (national, regional, municipality, organization multi-site), type of the health sector (public, private, or both) and the data sources (pharmaceutical wholesale suppliers, pharmacy records, electronic health records, other), setting (ambulatory, hospital, or both), years available, and type of data aggregation. We performed a descriptive analysis of the databases.

Results: Ten databases were identified, of which only 30% were publicly available, and 70% had restricted access; 90% reported national data; 40% included data from both public and private sectors; 30% were from pharmacy records, 40% from patient records. Eight databases contained separate information from both hospital and ambulatory settings. Information on the data granularity (individual or aggregate level data) was uncertain in 40%.

Conclusions: There are diverse data sources for DUR in Mexico, but access is still a barrier for researchers. To facilitate DUR in Mexico, access to the databases should be public (easy and transparent). The existing databases represent useful and inexpensive resources to provide timely information primarily about medicines volumes, drug-drug and drug-diseases interactions and other prescription errors, as well as on outcomes of healthcare (e.g. adverse drug events, including death). The existing databases constitute a good source of "real-world" health care data to guide health policy, however the creation of new databases, as well as the conjunction of them, is an important task to be undertaken in México.

Drug Utilization Research -> Other

44 | Access to insulin: A success story from the Sudan

Isam Eldin Mustafa

National Health Insurance Fund, Khartoum, Sudan

Background: Diabetes Mellitus (DM) is a global health concern where one in ten people are living with diabetes and half of the people who need insulin lack access to it. The economic burden of DM in Sudan is high where the prevalence of the disease is over 10%. Over 36% of the total expenditure of diabetes in children is spent on insulin in Sudan which represent 23% of the household income. The fluctuation of the exchange rate since referendum in 2011 is significant. The National Medical Supplies Fund (NMSF) developed a policy for procurement and pricing of insulin by signing a long-term contract with the supplier and subsidizing it by increasing prices of products with low prices and high consumption.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: 1. 1. To determine the impact of procurement and pricing policy on the price of mixed human insulin. 2. 2. To identify the affordability of insulin for insured and noninsured population in Sudan
Methods: A comprehensive review of the procurement documents of NMSF from 2011 until 2018 was performed. The affordability of patients to insulin price was done following the World Health Organization/Health Action International Methodology.
Results: The tender price of mixed human insulin in 2011 was 3.2 Euros (3.54 US$) which is fixed until 2019. The patient's price since 2011 until 2019 is 40 Sudanese Pounds(SDG), while the exchange rate in 2011 was 1US$ = 2.7 SDG, 5.4 SDG in 2012, 6.5 SDG in 2015, 15.8 SDG in 2016, 45 SDG in 2018. The worker of the lowest wage needs to work 1.5 days to purchase 10 ml 100 IU/ ml of insulin if is not insured, while the insured patient has to work 0.38 day.
Conclusions: The cross subsidy that the NMSF implements to reduce the price of insulin beside the long contract with the supplies of single source products have great impact on the reducing the economic burden of insulin. Further study to determine the adherence to insulin and predict the future sustainability of the supply of subsidized insulin is badly needed.

2329 | Pattern and risks perception of medical drugs use among adults in rural and urban communities, Southwest, Nigeria

Waheed Adedeji[1,2], David M Dairo[1,2], Patrick Nguku[3] and Fatai A. Fehintola[1,2]
[1]University College Hospital, Ibadan, Nigeria; [2]University of Ibadan, Ibadan, Nigeria; [3]Nigerian Field Epidemiology and Laboratory Training Program, Abuja, Nigeria

Background: Inappropriate drug use can result in untoward consequences including drug resistance, adverse drug reactions and death. Antimalarial, antibacterial, analgesics, and sedatives are among the commonly abused and inappropriately used drugs. There is a paucity of data on drugs use pattern and risks perception in the communities.
Objectives: To determine the pattern, risks perception and predictors of medical drugs use among adults in the rural and urban communities, Southwest, Nigeria.
Methods: A cross-sectional study was carried out among 999 adults aged 18 years and above, selected by multistage sampling. The questionnaires, adapted from previous studies, were pretested and interviewer-administered. The pattern of medical drugs used, prescribers, sources of drugs acquisition, and perception of drug risks were obtained. Risk perception was rated each for the commonly used drugs/drug classes and herbal concoction and ranked. The level of significance was set at 5%.
Results: The median (range)% prevalence of drug use [rural vs urban] were: lifetime, [57.3(16-79)vs 59(19.5-82.9)], current, [30.7 (7.4-62.3) vs 31.6(10.4-69.3)] and past use, [21.2 (9-30.0)]. Drugs used were majorly self-prescribed, median(range)%: 54.5(50-73.8) vs 61.9 (50.9-82.4), and obtained from patent medicine store, median(range)%: 71.3(67.2-79.3) vs 70.5(60.8-80.5). Most commonly used drugs were: artemether/lumefantrine, 227(78.3%) vs 210 (63.8%), Ampiclox^{R}, 94(43.5%) vs 126(53.2%), paracetamol, 283 (64.5%) vs 343(70.4%) and chlorpheniramine, 23(36.5%) vs 36(43.4%). The prevalence of antimalarial monotherapy was 21.7 vs 36.2%. More than half (51.2%) had low risk perception, and no difference in risk perception between rural and urban communities (x^2=0.5, p=0.51). Factors predictive of lifetime drugs used, odd ratio (95% CI) were: antimalarial [educational level, 2(1.4-2.8), presence of health facilities 0.5(0.3-0.9), male 0.6 (0.4-0.8), long distance to health facility, 1.7 (1.1-2.6)]; antibacterial[educational level,1.8(1.3-2.4), old age, 0.5 (0.3-0.9), medical illness, 1.68(1.04-2.7)]; analgesics {distance to health facility, 0.6(0.4-0.9), married, 0.51(0.3-0.8)}; and sedatives [educational level, (1.1-2.2), medical illness 2.1(1.3-3.3), alcohol 2.2,(1.5-3.3)].
Conclusions: The pattern of drugs use was similar in both communities. Drugs were mostly self-prescribed and obtained from patent medicine store. The risk perception of drugs was low. Factors predictive of drugs used were educational level, distance to the health facility, medical illness, and alcohol intake.

2330 | Real-world data analysis of potential drug-drug interactions in Greek community pharmacies

Georgios Poulentzas[1], Panagiotis Nikolaos Lalagkas[1], Lampros Tsiolis[1], Dimitra Hadjipavlou-Litina[1], Eleftherios Berberoglou[2], Antonios Douros[3,4,5], Christos Kontogiorgis[2] and Theodoros Constantinides[2]
[1]Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Democritus University of Thrace, Alexandroupolis, Greece; [3]McGill University, Montreal, QC, Canada; [4]Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada; [5]Institute of Clinical Pharmacology and Toxicology, Charité - Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Germany, Germany

Background: Drug-drug interactions may lead to severe clinical outcomes concerning patients' health, thus posing a serious threat to various fields of Public Health. To date, they have been significantly understudied in Greece.
Objectives: The goal of this study was to determine the prevalence of potential drug-drug interactions (pDDIs) and shed light on the factors responsible for the growth of this problem.
Methods: For this cross-sectional study, anonymous e-prescription data for the years 2012 -2017 were randomly obtained from 5 community pharmacies in Thessaloniki, the second-largest city in Greece. The sampling process was as follows: for each year patients were chosen by increasing identification number based on the coding of the pharmacies, ensuring randomized selection, and their e-prescription history was found. This process was repeated until 1.000 patients using 2 or more medicines concurrently for 3 or more months were gathered for each year. The study group assumed concurrent use of the medications if they were dispensed within a time period of 30 days. Using the online Drug Interaction Checker (www.drugs.com/drug_interactions.html), pDDIs were categorized depending on their clinical significance into major, moderate, and minor. Prevalence was

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

calculated as "Number of patients with at least one pDDI/Total number of patients" and logistic regression was used in order to identify the factors associated with increased risk of potential drug-drug interaction existence.

Results: During the study period, we collected e-prescription data of 8.320 patients, distributed in all 6 years. The overall prevalence of major pDDIs was 12.5% (45.4% for moderate pDDIs). The most common major pDDIs were those between calcium-channel blockers and statins (29.5% of pDDIs) followed by anticoagulant and PPIs (10.7% of pDDIs). The most common potential adverse effect of the assessed pDDIs (8.2%) was major myopathy. After adjustment, statistically significant associations seem to exist between risk of major pDDIs and number of administered drugs (Odds ratio 5.72, 95% CI: 4.87 - 6.72).

Conclusions: The prevalence of pDDIs in this study is higher than what has been reported in other European countries, with polypharmacy being the main contributing factor. Therefore, given that pDDI prevalence is considered a quality marker of prescribing practices, our data argue for a need for improvement in that area in Greece.

2343 | Women are started on a lower daily dose of metoprolol than men irrespective of dose recommendations

Linda C. Hendriksen[1,2], Paul D. van der Linden[2], Katia M.C. Verhamme[1], Bruno H. Stricker[1] and Loes E. Visser[1,3]

[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]Tergooi Hospital, Hilversum, Netherlands; [3]Haga Teaching Hospital, The Hague, Netherlands

Background: In a pharmacokinetic study of metoprolol, women had a two times higher maximal concentration in the blood and a significantly higher area under the curve than men after 100 milligrams (mg) twice daily. However, current guidelines do not distinguish dosage advices for women and men.

Objectives: This study was conducted to evaluate whether physicians prescribe the same starting dose of metoprolol for women and men under real-life circumstances. To see if differences occurred after the start of metoprolol, the dosing regime was followed up to 10 prescriptions.

Methods: A cohort analysis was performed in the Rotterdam Study (RS) and results were replicated in the Integrated Primary Care Information (IPCI) database - A Dutch GP database. The study population comprised all patients aged ≥18 years starting on metoprolol. The primary outcome was the mean daily dose in mg of the first metoprolol prescription. The secondary outcome was the dose regimen, expressed as the mean daily dose in mg per prescription up to 10 prescriptions. Data were analysed using an independent-samples t-test to compare the mean daily dose of metoprolol for both sexes per prescription. A linear regression analysis on the first prescription was used to adjust for age and in the RS also for indications.

Results: In total, 1,263 women and 870 men were included from the RS. The mean daily dose of the first prescription was significantly lower in women than in men; 61.1 mg and 65.9 mg respectively. Women received a 4.8 mg (95% CI -7.8, -1.8) lower dose. For both sexes, dosages increased over time and the difference remained statistically significant for the first three prescriptions. In total 23,074 women and 19,562 men were included from the IPCI database. Also in this database, the mean daily starting dose of metoprolol was significantly lower in women than in men; 57.3 mg and 62.0 mg respectively. The dose of the first prescription was 4.6 mg (95% CI -5.3, -4.0) lower in women. Dosages increased over the 10 prescriptions for both women and men and the difference in dose remained statistically significant. The dose of the first prescription was statistically significantly lower in women after adjustment for age in the RS and the IPCI database and after adjustment for indications in the RS.

Conclusions: In real life, women received a lower starting dose of metoprolol than men despite the absence of sex-adjusted dosage recommendations in guidelines. Furthermore, both women and men received lower dosages than recommended. This might mean that prescribers start at a lower dose because they fear that women are more prone to adverse reactions.

2397 | The association between dental opioid prescription characteristics and the risk of long-term use and overdose

Tonya Campbell[1], Diana Martins[2], Mina Tadrous[1,3,4], David Juurlink[1,4,5], J. Michael Paterson[1,4], Muhammad Mamdani[1,4,6], David Mock[4] and Tara Gomes[1,2,4]

[1]ICES, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Women's College Hospital, Toronto, ON, Canada; [4]University of Toronto, Toronto, ON, Canada; [5]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [6]Unity Health Toronto, Toronto, ON, Canada

Background: Dental pain is a common indication for opioid initiation, with a recent study indicating that 22% of people in Ontario, Canada who initiated opioid therapy between April 2015 and March 2016 were prescribed by a dentist. However, little is known regarding the risks of these medications when prescribed by dentists.

Objectives: To examine the association between initial dental opioid prescription characteristics and the risks of long-term use and harm.

Methods: We conducted a population-based cohort study of Ontario residents initiating opioids prescribed by a dentist between October 2014 and September 2016. The primary exposure was the average daily opioid dose dispensed at initiation, in morphine milligram equivalents (MME). Secondary exposures were the prescription duration (days supplied) and the formulation dispensed on initiation (immediate-release or long-acting). The primary outcome was continued opioid use at one year, and the secondary outcome was opioid toxicity within one year. Logistic regression was used to estimate the association between the initial prescription opioid characteristics and continued use, and opioid toxicity incidents were summarized using descriptive statistics.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 384,079 individuals initiating opioids prescribed by dentists, 1,810 (0.5%) remained on therapy for at least one year, and 152 (0.40 per 1,000 person-years) experienced an opioid toxicity incident. Compared to a daily dose of 20MME or below, an initial daily dose greater than 90MME was associated with a 67% increase in the odds of continued use (aOR 1.67; 95% CI 1.08 to 2.60). Relative to a duration of 3 days supplied or less, a duration greater than 14 days was associated with an almost threefold increase in the odds of continued use (aOR 2.87; 95% CI 1.86 to 4.41). In the secondary analysis, opioid toxicity rates increased with increasing daily dose initiated, and almost one-quarter of events (22.4%) occurred within the six weeks after initiation.
Conclusions: While persistent opioid use and toxicity occurred infrequently among dental patients newly receiving opioids, judicious opioid prescribing, including lower daily doses and shorter prescription durations following dental procedures may serve to reduce the risks of long-term use and opioid-related harms.

2423 | Psychotropic medication use in former ICU patients with mental health problems: A prospective observational follow-up study

Debbie G.A. Janssen[1], Joep Jonker[2], Diederik van Dijk[3], Eibert R. Heerdink[2,3,4], Toine C.G. Egberts[2,3] and Arjen J.C. Slooter[3]
[1]*Primary Healthcare Institute, Ministry of Defense, Utrecht, Netherlands;* [2]*Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands;* [3]*University Medical Center Utrecht, Utrecht, Netherlands;* [4]*HU University of Applied Sciences, Utrecht, Netherlands*

Background: An increasing number of patients with critical illness survive an admission to the intensive care unit (ICU) because of advancements in critical care. However, approximately 50-70% of these survivors develop mental health problems sometime after ICU discharge. Little is known on 'whether' and 'how' these patients are being treated.
Objectives: To describe the extent to which patients with mental health problems after admission to an Intensive Care Unit (ICU) initiate and use psychotropic medication.
Methods: All adult patients who stayed in the ICU of the University Medical Center Utrecht for 48 hours or more between 2013 and 2017, alive after 1 year and not admitted to the ICU with brain injury, were eligible. Questionnaires that included the Hospital Anxiety and Depression Scale (HADS), the Impact of Event Scale (IES/IES-R), and psychotropic medication use, were used to identify components of mental health problems, i.e. depression, anxiety and posttraumatic stress disorder (PTSD).
Results: Of the 1328 former ICU patients, 24.3% (n=323) had developed any of the mental health problems mentioned above. Of this group, 29.7% (n=96) used psychotropic medication one year after ICU discharge versus the 10.6% (n=107) of patients without these problems (OR 3.17, 95% CI 2.29-4.38). They were further 3.31 (95% CI 2.03-5.40) times more likely to initiate psychotropic medication (12.1% vs 3.7%) after ICU admission. Similar patterns were observed for individual groups of psychotropics: antidepressants, antipsychotics and benzodiazepines.
Conclusions: Former ICU patients with mental health problems were almost three times more likely to use and initiate psychotropic medication than former ICU patients without these problems, although only one third of the patients were treated with psychotropic medication. Future research should investigated whether mental health problems are properly diagnosed and treated in former ICU patients.

2495 | Older adults with colorectal cancer receive higher opioid dose

Sean P. Fleming, Tham T. Le and Julia F. Slejko
University of Maryland Baltimore, Baltimore, MD

Background: Initiatives to curb inappropriate opioid prescribing are known to have unintended consequences on exempt patient populations. This impact is not well understood among adults with colorectal cancer (CRC), which is prevalent across the lifespan though most common among older adults.
Objectives: To determine factors associated with opioid receipt and dose among adults with CRC by age group.
Methods: We performed a retrospective cohort study derived from a 10% random sample of enrollees within IQVIA™ Adjudicated Health Plan Claims Data from 2006-2015. The index date was the first CRC claim (ICD-9-CM codes 153xx-154xx) among individuals 18-64 years old continuously enrolled 12 months before and after the index. Opioid receipt was defined as any opioid prescription post-index. Baseline covariates were defined in the 12 months pre-index. A multivariable logistic model was used to examine the odds of opioid receipt, adjusting for pre-index opioid receipt, sex, Charlson Comorbidity Index, chronic pain, mental illness, concomitant psychoactive medication use, and CRC-related treatments. Morphine equivalent daily dose (MEDD) was calculated as (Quantity*Strength*Conversion Factor)/ Total Days Supplied. A multivariable generalized linear model with a Gamma distribution and log-link was used to examine MEDD post-index.
Results: Of 8,737 subjects, 51.63% (n=4,511) were 55 to 64 years, 34.53% (3,017) 45 to 54 years, 10.53% (920) 35 to 44 years, and 3.31% (289) ≤35 years. Overall, 34.54% received an opioid pre-CRC with a median (IQR) days supply of 10.0 (30.0) and MEDD of 8.3 (21.5). Post-CRC, 54.90% received an opioid with a median (IQR) days supply of 13.0 (40.0) and MEDD of 15.0 (34.4). Compared to individuals 55 to 64 years, the odds of opioid receipt were greater but not statistically significant among individuals aged ≤35 years (odds ratio (OR) 1.02; 95% Confidence Interval (CI): 0.77-1.35), 35 to 44 years (OR 1.03; 95% CI: 0.87-1.21), and 45 to 54 years (OR 1.07, 95% CI: 0.96-1.19). The average marginal effect (AME) associated with age under 35 years was -5.10 MEDD (95% CI: -10.83- -0.63), 35 to 44 years (-5.81; 95% CI: -9.18- -2.44), and 45 to 54 years (-2.09; 95% CI: -3.97- -0.21).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Opioid receipt did not differ between age groups post-index, yet the oldest age group had a significantly higher MEDD. This is concerning as older adults are more sensitive to medications, thus more likely to experience adverse events such as respiratory depression. Further research on the determinants of opioid dose may specify whether the observed associations are clinically justified or signals of potential age disparities in the treatment of pain in CRC.

2513 | Pain severity and analgesics use in the community-dwelling older population: A drug utilization study from Germany

Thi N.M. Nguyen[1,2], Dana C. Laetsch[1], Li-Ju Chen[1,2], Walter E. Haefeli[3], Andreas D. Meid[3], Hermann Brenner[1] and Ben Schöttker[1,2]

[1]*German Cancer Research Center (DKFZ), Heidelberg, Germany*; [2]*University of Heidelberg, Heidelberg, Germany*; [3]*Heidelberg University Hospital, Heidelberg, Germany*

Background: Chronic pain is common in the older population and a significant public health concern. However, comprehensive studies on analgesics use in this age group from Germany are scarce.

Objectives: This study aims to give a comprehensive overview on the prevalence of overall analgesics use and the prevalence of use of the most common therapeutic groups of analgesics in community-dwelling older adults from Germany.

Methods: A cross-sectional study was carried out using data from a German cohort of 2038 community-dwelling adults aged 63-89 years. Descriptive statistics and logistic regression models were applied to assess the utilization of analgesics by age, sex, pain severity, pain duration and locations.

Results: One out of four (25.0%) study participants was suffering from high intensity or disabling pain (grades II-IV). However, less than one out of four (22.9%) used any analgesic drugs, and about half (50.5%) of those still reported to suffer from high intensity or disabling pain (grades II-IV) despite the intake of analgesics. Among analgesics users, occasional non-steroid anti-inflammatory drugs (NSAIDs) use was the most frequent pain therapy (in 43.6% of user), followed by metamizole (dipyrone) use (16.1%), regular NSAIDs use (12.9%), strong opioids use (12.7%) and weak opioids use (12.0%). In multivariate logistic regression models, higher age, higher pain severity, longer pain duration, abdominal pain and back pain were statistically significantly associated with opioids use. Metamizole use was also statistically significantly associated with higher pain severity but inversely associated with pain duration.

Conclusions: A significant number of older German adults are affected by high intensity and disabling chronic pain despite receiving analgesics. Long-term studies are needed to compare the effectiveness and safety of different treatments for chronic pain in older adults.

3719 | St John's Wort: Utilization during pregnancy and pregnancy outcomes

Wiebke Schaefer, Nadine Wentzell and Ulrike Haug

Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Germany

Background: Pregnant women may be prone to using complementary and alternative medicine, such as St. John's Wort (St. John's) for the treatment of mild depressive disorders. However, little is known about the utilization of St. John's during pregnancy. In Germany, high-dose preparations of St. John's can be reimbursed by statutory health insurances, enabling to study exposure to St. John's based on German claims data.

Objectives: To characterize pregnancies exposed to high-dose preparations of St. John's and to describe the outcomes of these pregnancies.

Methods: Using the German Pharmacoepidemiological Research Database (GePaRD) with data on ~1.5 million pregnancies between 2006 and 2016, we identified pregnancies with exposure to high-dose St. John's via outpatient dispensations. We characterized these pregnancies regarding the timing of dispensation of St. John's preparations, the use of other antidepressants in the year before or during pregnancy, concomitant use of potentially interacting drugs, as well as the relative frequency of pregnancy outcomes compared to all other pregnancies.

Results: We identified 496 pregnancies with dispensation of a high-dose St. John's preparation in at least one trimester. Of these, 386 (78%) had a dispensation during the first trimester only, and 16 pregnancies (3%) had a dispensation in all trimesters. About one third already had a dispensation of St. John's in the year before pregnancy. In 21% of all pregnancies exposed to St. John's, the mothers had a dispensation of other antidepressants in the year before pregnancy and 12% during pregnancy (9% in the first trimester). Concomitant use of potentially interacting drugs during pregnancy was infrequent, with less than 1% of all pregnancies being exposed to such drugs in one of the trimesters. Compared to the rates previously published for all pregnancies in GePaRD, pregnancies exposed to St. John's less frequently resulted in live birth (89% vs. 94%), while the rates for induced abortions/stillbirths and ectopic pregnancies were about two times higher (7.9% vs. 3.8% and 2.0% vs. 1.4%, respectively). All non-live births except for one stillbirth occurred in pregnancies exposed during the first trimester only.

Conclusions: Our results suggest that St. John's is used as an alternative to other antidepressants in some pregnancies, but is also newly dispensed for treatment during pregnancy. Further investigations are needed to explore potential reasons why the rates for non-live births were higher among pregnancies exposed to St. John's compared to other pregnancies.

3732 | Antidepressant use among adults patients in primary care in Brazil: Results of a national survey

Natalia P.B. Torres, Juliana Alvares Teodoro, Augusto AfonsoGuerra Junior and Francisco A. Acurcio
Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Antidepressant medicines are widely prescribed. In the last years, international population-based studies have identified growth in their use. Considering the limited number of studies on this topic in Brazil, it is important to investigate and describe characteristics of their use, providing information about a middle-income country.
Objectives: To estimate the prevalence of antidepressant use and identify its associated factors among adults in primary care of the Brazilian National Health System (NHS).
Methods: This study is part of the National Survey on Access, Use and Promotion of the Rational Use of Medicines in Brazil - Services, a cross-sectional and evaluative study, consisting of information collection from a representative sample of cities, primary health care services and patients in the five regions of Brazil. Patients were interviewed in primary health care services, with a specific questionnaire. An estimate of 1,800 patients would be interviewed by region of the country. At the end, 8,803 interviews were conducted, from July to December 2014. The outcome considered was use of any antidepressant in the past 30 days. We performed a descriptive analysis of the population and the antidepressants used. The association between antidepressant use and demographic, socioeconomic, clinical and lifestyle-related characteristics was evaluated using logistic regression model.
Results: The prevalence of antidepressant use was 6.8% (95% CI 6.2 - 7.3). Most users who self-reported previous diagnosis of depression (70.6%) and who were extremely depressed/anxious (75.6%) did not report antidepressant use, suggesting underuse. The most commonly drugs used were fluoxetine, amitriptyline and venlafaxine. After all adjustments, the multivariate analysis found that the use of antidepressants is more likely in females, who self-reported depression and anxiety/depressive status, that practices polypharmacy and use psychotropics, have alcohol abstinence, a higher socioeconomic status and being of the white ethnicity/race.
Conclusions: The prevalence of antidepressant use observed in Brazil is lower than in USA and some European countries. The factors associated with its use are consistent with the literature. The findings suggest that there may be inequity in access to drug treatment for depression in the Brazilian NHS. Although patients have a universal right to health in Brazil, the inequities found, especially for non-white individuals and those from lower social classes, show that it is necessary to improve actions to ensure access to treatment of depressive disorders by primary care users.

3748 | Variations in long-term opioid use definitions in observational research: A systematic review of studies using routinely collected data

Juliana de Oliveira Costa, Claudia Bruno, Navya Baranwal and Sallie-Anne Pearson
Centre for Big Data Research in Health, Sydney, Australia

Background: Opioid treatment guidelines do not recommend long-term (LT) use due to the development of tolerance and risk of dependence. However, there is no consensus on the definition of LT opioid use, creating challenges for measurement in real-world settings.
Objectives: To catalogue the definitions and terminology relating to LT opioid use and the rationale for definitions in observational research using routinely collected data.
Methods: We conducted a systematic review of observational studies evaluating LT opioid use from routinely health administrative data sets or electronic health records. We searched MEDLINE and Embase and conducted hand searches for studies published between January 2000 and July 2019. Two independent reviewers screened abstracts for 4,056 articles and 205 full-text manuscripts. We also evaluated study reporting using selected items from the REporting of studies Conducted using Observational Routinely-collected health Data (RECORD) checklist.
Results: We included 128 studies; most were from the US (82%), published between 2016 and 2019 (67%), used pharmacy dispensing data (86%) and had nationwide data coverage (46%). Common terminology included "Long-term use" (28%), "Chronic use" (21%), "Chronic therapy" (11%) and "Long-term therapy" (9%). We identified 85 different definitions of LT opioid use, most commonly 90 days of cumulative or continuous use within a year (22%). To derive definitions, studies generally combined one measure of duration, such as supply days/days of use (67%), episode length (22%), fills in 3-months (5%) with additional criterion (40%); continuity between the fills (25%), number of fills (13%), defined daily doses/ morphine milligram equivalents (5%), other (8%). Definitions were mostly based on previous publications (63%), clinical judgment (15%), or empirical data (3%); 10% of studies tested more than one definition. LT opioid use was not clearly defined in 21 studies and 38 studies did not specify the opioids evaluated.
Conclusions: While there is an increasing interest in evaluating LT opioid use due to its clinical and economic burden, there is a large variability in definitions used and poor reporting of the rationale and implementation of the definitions, impacting on research reproducibility.

3819 | Biologic use and persistence for Crohn's disease after intestinal resection in the United States 2002-2018

Joehl T. Nguyen[1], Edward L. Barnes[2], Swetha Srinivasan[1] and Alan C. Kinlaw[1]
[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC;* [2]*University of North Carolina School of Medicine, Chapel Hill, NC*

Background: Patients with Crohn's Disease (CD) are often treated with surgical resection but postoperative recurrence leading to repeat resection remains common. Biologic therapy is a recommended

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

prophylactic strategy in patients with CD, but data are limited on real-world use and outcomes in the postoperative setting.

Objectives: To describe baseline characteristics and postoperative biologic treatment patterns for patients with CD after intestinal resection.

Methods: Using IBM Watson Health MarketScan data 2002-2018, we identified patients with diagnosis of CD at intestinal resection, and excluded patients with prior resections during a 2-year baseline period. We identified claims for anti-tumor necrosis factor-α, anti-integrin, and anti-interleukin 12/23 agents. We used bivariate analysis to assess whether baseline covariates were associated with biologic use within 6 months after surgery. We used Kaplan-Meier-based cumulative incidence to estimate 6-month risk of treatment discontinuation (with 95% confidence intervals, CI), defined as switching or stopping biologic therapy outside the FDA-labeled treatment frequency (including a 30-day grace period). The last day of the allowable gap period was defined as the discontinuation date among patients who were non-persistent on their postoperative biologic.

Results: Among 5373 patients who had surgery for CD, 1547 (28.8%) patients received a biologic within 6 months after surgery. 50.9% were female and 72.3% had received a partial colectomy or ileocolic resection at baseline. Compared to patients who did not initiate biologics within 6 months after surgery, these patients were younger (mean age 36 vs 41 years), more commonly from the South and West regions, and had similar prevalence of colonoscopy prior to surgery (78.3%). Most patients who used biologics within 6 months after surgery were treated with infliximab (38.5%) and adalimumab (55.3%), while 5.2% of patients were treated with vedolizumab. The 6-month risk of discontinuation for patients treated with infliximab, adalimumab, and vedolizumab was 18.4% (95% CI 15.2%-21.6%), 31.6% (95% CI 28.4%-34.8%), and 19.8% (95% CI 10.8%-28.8%), respectively. 36.3% of non-persistent patients received a colonoscopy after surgery and before discontinuing their initial postoperative treatment.

Conclusions: Patients on postoperative adalimumab were more likely to discontinue their prescribed therapy through 6 months compared to infliximab and vedolizumab. Further analyses should examine postoperative treatment channeling for CD, including combination therapy with non-biologics.

3865 | Are aclidinium and aclidinium/formoterol used according to their approved indication in Europe? Results of a multicountry drug utilization postauthorization safety study

Elena Rivero-Ferrer[1], Anna Julia Witzleb[2], Morten Olesen[3], Estel Plana[1], Jaume Aguado[1], Nuria Saigi-Morgui[1], Annalisa Rubino[4], Sami Z. Daoud[5], Alejhandra Lei[6], Susana Perez-Gutthann[1], Tania Schink[7], Nina S. Kristiansen[3], Anton Pottegård[3] and Cristina Rebordosa[1]

[1]RTI Health Solutions, Barcelona, Spain; [2]Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Germany; [3]University of Southern Denmark, Odense, Denmark; [4]AstraZeneca, Cambridge, United Kingdom; [5]AstraZeneca, Gaithersburg, MD; [6]AstraZeneca, Barcelona, Spain; [7]Leibniz Institute for Prevention Research and Epidemiology-BIPS, Bremen, Germany

Background: Aclidinium bromide was approved in the European Union for the treatment of chronic obstructive pulmonary disease (COPD) in adult patients in 2012 and aclidinium/formoterol in 2014. A drug utilisation study in three European countries is part of the pharmacovigilance plan.

Objectives: To evaluate the potential indication of aclidinium, and aclidinium/formoterol, and characteristics of new users of study medications in Denmark, Germany, and the United Kingdom (UK).

Methods: Cohorts in the Danish National Health Databases (2015-2017), the German Pharmacoepidemiological Research Database (2015), and the UK Clinical Practice Research Datalink (CPRD GOLD, 2015-2017) included new users treated with long-acting muscarinic antagonists (LAMA) (aclidinium, aclidinium/formoterol, tiotropium, other LAMA), long-acting beta2-agonists (LABA), or LABA/inhaled corticosteroids (LABA/ICS). On-label was defined as use in adults with a diagnosis of COPD with or without asthma. Off-label use was defined as use in patients aged < 18 years or use in patients with a recorded diagnosis of asthma without a COPD diagnosis. Absence of a recorded diagnosis of COPD and asthma was classified as unknown indication.

Results: There were 4,871 users of aclidinium and 2,153 users of aclidinium/formoterol in the UK, 2,836 users of aclidinium and 2,586 of aclidinium/formoterol in Denmark, and 9,961 users of aclidinium and 10,069 users of aclidinium/formoterol in Germany. Among users of aclidinium, a COPD diagnosis was present in 89% of users in the UK, 87.4% in Germany, and 56.0% in Denmark. For aclidinium/formoterol, this percentage was 90.5% in the UK, 92.8% in Germany, and 57.7% in Denmark. There was no or minimal paediatric use. Among users of aclidinium, diagnosis of asthma with no COPD diagnosis occurred in 5.0% in the UK, 5.4% in Germany, and 8.8% in Denmark. For aclidinium/formoterol, it occurred in 3.2% in the UK, 2.6% in Germany, and 3.0% in Denmark. The indication was unknown in 6% of users of aclidinium in the UK, 7.2% in Germany, and 35.0% in Denmark. For aclidinium/formoterol, this percentage was 6.3% in the UK, 4.6% in Germany, and 39.2% in Denmark.

Conclusions: Aclidinium and aclidinium/formoterol are prescribed mainly according to the approved indication. Based on recorded diagnoses, it cannot be ruled out that a patient may have had childhood asthma that later resolved or evolved to asthma-COPD syndrome in adulthood. Paediatric use was anecdotal. The high proportion of 'unknown indication' in Denmark is driven by the lack of primary care diagnoses.

3879 | Trends in first opioid prescribing in more than 600000 opioid-naïve and cancer free patients in Sweden - Drugs, doses, and diagnoses

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Carola Bardage, Maria Grünewald, Paulina Tuvendal and Rickard Ljung
Swedish Medical Products Agency, Uppsala, Sweden

Background: Opioids play an important role in health care as analgesics; during and after surgical procedures, in severe acute pain and cancer pain. Treatment with opioids can pose a risk of addiction. In the United States, opioid dependence in an increasing proportion of the population is one of the biggest public health problems. Therefore, there is reason to follow the prescription of opioids over time in Sweden This is to pay attention to the medical care of these drugs and urge caution and proper use in accordance with product information, treatment recommendations and guidelines.
Objectives: The objective was to describe the prescribing of opioids, indications for treatment, who prescribed, what is prescribed, and any risk factors for future overconsumption and dependence.
Methods: This cohort study used individual data of unique users of opioids linked from several national-coverage health data registers to evaluate time trends to assess first time prescription of opioids by drug type, doses, and diagnoses, in adults aged 18-64 years in Sweden. All patients with a first prescription of an opioid in 2012 to 2015 were studied and the date of the first prescription was defined as their index date. Patients with any prescription of an opioid within 6.5 years prior to index date were excluded. Any patient with a record of a cancer, except non-melanoma skin cancer, prior to or 3 months after index date was excluded.
Results: A total of 617,568 patients aged 18-64, 50 % men, were prescribed opioids for the first time. One third of the prescriptions were from specialized out-patient care (33 %) and primary care (28,3 %), respectively. Dental care accounted for 9 % of all first prescriptions. The fixed combination of codeine and acetaminophen was the most commonly prescribed opioid with 322 818 patients (52 %), followed by tramadol (120 271, 19 %) and oxycodone (104 418, 17 %). From 2012 to 2015 tramadol as first prescribed opioid dropped from 26 % to 14 % and oxycodone increased from 10 % to 24 %. Fracture of the lower leg was the most common indication in in-patient care and dorsalgia in specialized out-patient care for the first prescription of an opioid. The prescribed amount of opioid, with respect to the analgesic effect (when comparing morphine equivalents) was equivalent regardless of the opioid prescribed.
Conclusions: Exploring trends in opioid prescriptions to opioid naïve cancer free patients in Sweden from 2012 to 2015 does not show an increase in opioid use. There has been a shift from tramadol to oxycodone, but codeine in fixed combination with acetaminophen is by far the most commonly prescribed opioid.

4001 | Prevalence of chronic drug use in pediatrics: Comprehensive overview based on German claims data

Oliver Scholle[1], Antje Neubert[2], Oliver Riedel[1], Irmgard Toni[2] and Ulrike Haug[1,3]

[1]*Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany;* [2]*Universitätsklinikum Erlangen, Erlangen, Germany;* [3]*University of Bremen, Bremen, Germany*

Background: The frequency and type of drug prescriptions in children and adolescents require careful monitoring given the uncertainties and risks associated with pediatric drug use. Existing studies in this field using large health care databases, however, focused on any drug use (i.e., at least one prescription of a certain drug) while recurrent drug use may even be more relevant for monitoring.
Objectives: To provide a comprehensive overview of frequencies and types of recurrent drug prescriptions in children and adolescents in Germany in 2016.
Methods: We used the German Pharmacoepidemiological Research Database (GePaRD)—a claims database covering ~17% of the German population. We identified children and adolescents aged 0-17 years with continuous insurance coverage in 2016 and assessed the prevalence of recurrent prescriptions (≥3 prescriptions of the same drug/therapeutic subgroup in 2016) based on ATC codes. We stratified the analyses by age and sex.
Results: Among 1.5 million children and adolescents included overall, the prevalence of recurrent drug prescriptions was 102 per 1,000 in girls and 87 per 1,000 in boys. For comparison, the prevalence of any drug prescriptions was more than five times higher. Among girls, the prevalence of recurrent drug prescriptions ranged between 43 (<2 years) and 207 per 1,000 (13-17 years). In 2-12-year-old girls, systemic antibiotics (ATC subgroup J01) had the highest prevalence of recurrent use (2-5 years: 66 per 1,000; 6-12 years: 31 per 1,000). In girls aged 13-17 years, sex hormones (ATC subgroup G03) had the highest prevalence of recurrent use (146 per 1,000). Furthermore, unlike other age and sex groups, this subgroup showed a prevalence above 10 per 1,000 for levothyroxine. Among boys, the prevalence of recurrent drug prescriptions ranged between 61 (<2 years) and 98 per 1,000 (13-17 years). In 2-5-year-old boys, systemic antibiotics had the highest prevalence of recurrent use (73 per 1,000). In older boys (6-17 years), psychoanaleptics (ATC subgroup N06) showed a higher prevalence than antibiotics. Methylphenidate was the most frequently prescribed recurrent drug among boys aged six years and older (6-12 years: 23 per 1,000; 13-17 years: 26 per 1,000).
Conclusions: This description of recurrent drug prescriptions provides important insights on chronic drug exposure in children and adolescents and highlights marked differences between age and sex groups. The high prevalence of three or more antibiotic prescriptions in preschoolers and of levothyroxine in girls aged 13-17 years are striking and require further consideration.

4008 | Feasibility of studying the use of tissue-agnostic cancer drugs in population-based European health databases

Xabier Garcia de Albeniz[1], Nuria Riera Guardia[1], Lia Gutierrez[1], Shahram Bahmanyar[2], Patrick Blin[3], Cécile Droz[3], Miriam Heinig[4],

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Marie Linder[2], Nicholas Moore[3], Renate Schulze-Rath[5], Janet Sultana[6], Gianluca Trifirò[6], Wei Wei Zhang[7] and Jihong Zong[7]
[1]RTI-Health Solutions, Barcelona, Spain; [2]Centrum för Läkemedelsepidemiologi, Karolinska Institutet, Stockholm, Sweden; [3]University of Bordeaux, Bordeaux, France; [4]Leibniz Institute for Prevention Research and Epidemiology - BIPS GmbH, Bremen, Germany; [5]Bayer AG, Berlin, Germany; [6]Università degli Studi di Messina, UNIME, Messina, Italy; [7]Bayer US LLC, Whippany, NJ

Background: Tissue-agnostic cancer drugs, indicated based on tumour biology rather than its anatomic origin, represent a state of the art in cancer therapeutics. Larotrectinib is an oral inhibitor of three kinases (TRKA, TRKB, TRKC) active in several tumours. Larotrectinib is approved by the US FDA and by the EMA as monotherapy in patients with solid tumours that have an *NTRK* gene fusion without an acquired resistant mutation, that are metastatic, or where surgical resection is likely to result in severe morbidity, or that have no satisfactory alternative treatment options or that have progressed following treatment.

Objectives: To assess the feasibility of conducting a drug utilisation study of larotrectinib using various European data sources.

Methods: We developed a feasibility assessment form with questions targeted to assess the data availability on expected use of larotrectinib and other cancer drugs, tumour diagnosis and its status when a drug is started, and biomarker testing, specifically *NTRK* fusion and tests results. Researchers from seven European databases contributed; we present the results from six: German Pharmacoepidemiological Research Database (GePaRD), Swedish National Health Registers (SNHR), Norwegian Health Databases and Registers (NHDR), System National de Données de Santé (SNDS), Italian Health Databases of Caserta/Palermo (IHD), and Public Health England (PHE).

Results: All databases allow a characterization of demographics, comorbidities, and health care utilization, as well as oral cancer drugs dispensed by ambulatory pharmacies. Full information on oral cancer drugs dispensed by a hospital pharmacy (likely for larotrectinib) is available in all except SNDS and GePaRD. For SNDS only, data of new expensive cancer drugs are available, while in GePaRD, the information available is the administration of a drug in a hospital. No database contains information on specific genetic tests or their results, except for PHE. PHE has information on the most common tests run for somatic genetic alterations, as well as a field ("other") for less common tests. Except for IHD, all databases are linkable to cancer registries, although due to data protection laws involving a burdensome effort, linkage in GePaRD may not be feasible.

Conclusions: Only PHE contains all elements to evaluate the use of larotrectinib in routine practice. Nevertheless, PHE recency, a lag time up to 5 years for 100% completeness, and the lack of published research on cancer with genetic alterations should be considered. The custodians of the rest of the databases are not aware of plans to add tumour genetic information.

4034 | The one percent: Screening Danish nationwide drug utilisation data for patterns of misuse

Lars Christian Lund, Mette Reilev, Anton Pottegård and Jesper Hallas
University of Southern Denmark, Odense, Denmark

Background: Measures of inequality, e.g. the Gini coefficient and income shares, are frequently used when analysing economic data but have rarely been applied to drug utilisation. Large inequalities in drug utilisation have previously been shown to be a marker of drug misuse. Using these measures in large-scale health databases may thus identify drugs with an unsuspected misuse potential.

Objectives: To describe and screen the Danish population's drug use for inequal drug use patterns.

Methods: Data from the Danish national prescription registry filled by patients aged 40+ during 2018 were analysed. Drugs administered intravenously or without a defined daily dose were excluded. As measures of inequality, we calculated the Gini coefficient, the fraction of all drug use consumed by the 1% most intensive users (1-percentile ratio) and the mean DDD used per day. The Gini coefficient measures statistical dispersion, with a coefficient of 1 representing total inequality while 0 represents total equality. Signals were sorted in descending order according to Gini coefficient and 1-percentile ratio.

Results: 43,890,792 prescriptions filled by 2,474,195 individuals were analysed. The three drugs with the highest Gini coefficient were methylprednisolone (0.88), docusate sodium for rectal administration (0.81) and oxycodone (0.80). The highest 1-percentile ratio was found for methylprednisolone (0.39), cyclizine (0.23) and loperamide (0.22). The median daily DDD consumed in the highest percentile was 3.2 for methylprednisolone, 2.8 for oxycodoone, 1.2 for cyclizine and 1.1 for loperamide.

Conclusions: The uneven distribution of methylprednisolone use was expected and is justified by the drug's clinical application in emergency immunosuppression.

The signals for loperamide and cyclizine were unexpected and warrant further investigation. When taken in supratherapeutic doses, loperamide acts as an opioid agonist. Misuse of loperamide is an emerging problem in the nordic countries but has hitherto been assumed to be restricted to over the counter sale of the drug. Cyclizine has a sedating effect and is hallucinatory when taken in large doses. It is likewise sold over the counter, suggesting that the true magnitude of misuse might be even larger.

4079 | Patterns and trends of idarucizumab use in an Italian region: A probabilistic record-linkage approach in a real-life setting

Niccolò Lombardi[1], Valentina Brilli[1], Giada Crescioli[1], Alessandra Bettiol[1], Ippazio Cosimo Antonazzo[2], Giampiero Mazzaglia[2], Stefano Fumagalli[1], Guido Mannaioni[1], Alfredo Vannacci[1] and Rosa Gini[3]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. [1]University of Florence, Florence, Italy; [2]University of Milano-Bicocca, Monza, Italy; [3]Regional Agency for Healthcare Services of Tuscany, Florence, Italy

Background: Idarucizumab is a specific reversal agent for dabigatran, a direct oral anticoagulant. In 2015, idarucizumab was approved in Europe to quickly restore coagulation and it is currently subject to additional safety monitoring. The drug is administered only during inpatient or emergency care: in such settings, its use is poorly captured by most real-world databases.

Objectives: To retrieve individual level information on idarucizumab use from an Italian record-linkage claims database in order to describe main characteristics of users.

Methods: Italy has a regional-based, universal coverage healthcare system. Healthcare delivered to each inhabitant of Tuscany, an Italian region, is registered in a record-linkage claims database (RLCD). This information can be traced at individual level using an encrypted identification code, except in the case of medicines administered in Inpatients or Emergency Care (IEC), where only date and ward of administration are recorded. All person-years (PYs) exposed to dabigatran from January 2015 to December 2018 were calculated from RLCD, using defined daily doses (DDDs) to estimate duration of each recorded dispensation. Idarucizumab use during the study period was identified from IEC, and incidence rate was calculated over PYs of dabigatran use. To identify subjects treated with idarucizumab, emergency admissions and hospital discharge records were probabilistically linked to dabigatran users, matching date and ward of admission as retrieved from RLCD. A further selection was made by a manual check of the diagnoses compatible with the indications of use of idarucizumab. Linked users were described in terms of indication and followed-up for 30 days to assess mortality.

Results: During the study period, 26,821 PYs of dabigatran use were observed, and 112 administrations of idarucizumab were recorded, corresponding to 4.2 (95% CI: 3,4-5,0) per 1,000 PYs. Overall, 103 idarucizumab administrations (92.0%) were linked to at least one patient, while 50 (44.6%) were uniquely linked to 47 patients. Most of them were men (55.3%), aged ≥80 years (68.1%). Indications were emergency surgical procedures and life-threatening bleeding in 17 (36.1%) and in 30 subjects (63.9%), respectively. Overall, 30-days mortality was 17.0% (N=8).

Conclusions: This analysis demonstrates the potential of the Tuscany database in retrieving patient-level information on idarucizumab use and sets the stage for post-marketing surveillance on its safety profile in a real-life setting.

4096 | Dispensing practices of antibiotics by community pharmacies in two districts of Nepal

Nisha Jha[1], Sunil Shrestha[2] and Pathiyil Ravi Shankar[3]

[1]KIST Medical College, Kathmandu, Nepal; [2]Nepal Cancer Hospital and Research Center, Kathmandu, Nepal; [3]Oceania University of Medicine, Apia, Samoa, Samoa, Samoa

Background: Use of antibiotics as an over the counter medicine is very common in Nepal. In a developing country like Nepal, the implementation of the existing antibiotic use guidelines is very difficult. Various factors contribute to irrational use of antibiotics including self-medication, irrational prescribing and dispensing.

Objectives: To evaluate the antibiotic dispensing practices of community pharmacies and the association, if any, between the educational qualification, experience, professional license and the location of the pharmacy with the antibiotic dispensing practices.

Methods: Design: A cross sectional prospective study

Setting: Community pharmacies of two districts of Nepal. Inclusion criteria: Community Pharmacies registered at Department of Drug Administration of Nepal and willing to participate in the study. Exclusion criteria: Community pharmacies not willing to participate in the Study. Study site and duration: Study was conducted in Kathmandu and Lalitpur districts from October 2018 to November 2018 among the community pharmacies listed in different directories. The sample size was 78 with a 5% margin of error, 95% confidence level, and 50% response distribution and random sampling method was used. Data was collected using a questionnaire. Written informed consent was obtained. The data was analyzed using SPSS for Windows.

Results: Out of 78 pharmacies, 12 (15.4%) were unregistered and 54 (69.2%) were located in Kathmandu district. Antibiotics dispensed without a prescription were 67 (85.9%). Fifty-two (66.7%) pharmacists did not ask for prescription before dispensing antibiotics. The practice of brand substitution was seen in 43 cases (55.1%). Antibiotics per prescription was three in 51 cases (65.4), followed by two antibiotics in 27 (34.6%) and this was significant in the pharmacies near hospital and periphery. Advice regarding completing the course of antibiotics were given by 59 (75.6%) pharmacies and insufficient number of antibiotics dispensed were 23 (29.5%). Nine pharmacists (11.5%) replaced prescribed antibiotics with cheaper brands. Azithromycin 69 (88.5%) was the most commonly dispensed antibiotic followed by amoxycillin 68 (87.2%).

Conclusions: Dispensing antibiotics without a prescription is seen in majority of pharmacies which can be a big threat towards using antibiotics rationally. The findings of this study may necessitate re-evaluation of the guidelines framed for improving safe and rational use of antibiotics.

4151 | Statin use and melanoma recurrence

Chrystelle Kiang[1], Anne Fia Grann[2,3], Uffe Heide-Jørgensen[2], Thomas P. Ahern[4], Timothy L. Lash[1,2], Henrik Toft Sørensen[2] and Deirdre P. Cronin-Fenton[2]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]Emory University, Atlanta, GA; [2]Aarhus University Hospital, Aarhus, Denmark; [3]Department of Clinical Oncology, Aarhus, Denmark; [4]University of Vermont, Burlington, VT

Background: The use of statins to lower risk of cardiovascular disease is well established, but there is evidence that statins have positive pleiotropic effects including the reduction of cancer recurrence. In addition to inhibiting the synthesis of cholesterol, statins can prevent the synthesis of isoprenoids and reduce cancer cell proliferation. Lipophilic statins are more readily available in extrahepatic tissue than hydrophilic statins, so the pleiotropic effects could differ by type of statin.

Objectives: To investigate whether an association exists between post-diagnostic statin use and melanoma recurrence among melanoma patients, and whether it differs by type of statin.

Methods: We conducted a prospective cohort study of residents in Denmark diagnosed with localized or regional melanoma between 1997 and 2009 using the Danish Cancer Registry. Prescription data for lipophilic and hydrophilic statins was obtained from the Danish National Prescription Registry. Melanoma recurrence, defined as tumor growth in the same organ, near the site of the original tumor, or metastases to a distant organ, was obtained from the Danish National Pathology Registry. We followed patients from 90 days after melanoma diagnosis until December 31 2011. We modeled statin exposure as a time-varying exposure updated daily and lagged by one year. We used Cox regression to estimate the association between any statin use and melanoma recurrence, adjusting for cancer stage, sex, age, and potentially confounding co-medications: aspirin, NSAIDs, vitamin K coagulants, steroids, diuretics, ACE-inhibitors, and beta-blockers. We considered statins overall, and separately according to lipophilic versus hydrophilic statins.

Results: Of 12,906 melanoma patients, 2,241 (17%) were statin users. Users of any statin experienced fewer recurrences than non-users, with a 5-year adjusted hazard ratio (aHR) of 0.80 (95% confidence interval 0.65, 0.98). Most prescriptions were for lipophilic statins (80%) and the aHR associating melanoma recurrence and lipophilic statin use was 0.78 (95% CI 0.63, 0.98). The aHR associating melanoma recurrence and hydrophilic statin use was 0.82 (95% CI 0.53, 1.26).

Conclusions: In this cohort of Danish melanoma patients, use of any statin was associated with a reduced risk of melanoma recurrence.

4188 | Polypharmacy at the time of opioid overdose in older adults on long-term opioid therapy

Nazleen F. Khan, Katsiaryna Bykov and Joshua J. Gagne
Brigham and Women's Hospital, Boston, MA

Background: The opioid epidemic is a pressing public health concern that affects patients of all ages, including older adults. In 2017, opioid overdose was responsible for nearly 9,000 deaths among individuals aged 55 and older in the US. Polypharmacy is also common in older adults who take opioids and may further contribute to overdose events. However, little is known about the prevalence of polypharmacy at the time of overdose in older adults who use opioids long-term.

Objectives: To identify patterns of concurrent opioid and non-opioid medication utilization at the time of overdose among long-term opioid users ≥ 65 years of age.

Methods: We used data from 2014 through 2017 from a large US commercial insurance database to conduct a descriptive study of opioid and non-opioid prescription use among older long-term opioid users who experienced an overdose. The source population consisted of patients with at least 180 days of continuous enrollment and 90 days of continuous opioid use prior to their first overdose at age 65 or older in the database between January 1, 2015 and December 31, 2017. Comorbidities were assessed in the 180 days prior to and including the overdose date. Opioid overdose was defined as an event resulting in an emergency room visit or hospitalization based on International Classification of Diseases codes. We assessed the number of active non-opioid prescriptions on the overdose date and most common non-opioids and opioids active on the overdose date. Active medications were defined as prescriptions with a dispensing date and days' supply that overlapped with the overdose date.

Results: We identified 499 older adults on long-term opioid therapy who experienced an overdose between 2015 and 2017. Mean age at the time of overdose was 73.4 years, 66.3% were female, and 94.4% had a diagnosis for a chronic pain condition (osteoarthritis, rheumatoid arthritis, postherpetic neuralgia, diabetic neuropathy, fibromyalgia, back or neck pain, other arthritis, and/or other neuropathy). On the overdose date, 80.4% of patients had active prescriptions for four or more non-opioid medications, and 98.8% had active dispensings for one or more non-opioids. Gabapentin (29.7%), levothyroxine (20.6%), and furosemide (19.2%) were the most common active non-opioids on the overdose date.

Conclusions: Polypharmacy is common on the overdose date among older adults on long-term opioid therapy and frequently involves drugs that could interact with opioids to increase overdose risk. Interventions may focus on dispensing opioid antagonists or deprescribing other medications to reduce the potential for drug-drug interactions.

4194 | Effects on seizure activity of co-prescribing anti-epileptic drugs and antidepressant medications among African Americans with epilepsy

Courtney L. Schlusser[1], Regine Haardoerfer[2] and Nancy J. Thompson[2]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Emory University, Atlanta, GA

Background: People with epilepsy (PWE) often experience comorbid depression, a known risk factor for seizure activity. To treat comorbid epilepsy and depression, PWE are co-prescribed anti-epileptic drugs (AEDs) and antidepressants. The risk of seizure activity may decrease

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

when depression is reduced through antidepressant medication utilization.

Objectives: To determine the effect of concomitant use of AEDs and antidepressants on seizure activity among African Americans with epilepsy in a southeast hospital system.

Methods: Data were obtained from medical records of African American adults with an epilepsy diagnosis who sought services at an inner-city hospital in the southeast. We identified 126 patients who had a seizure event between 2010-2015, were prescribed an AED, and visited the hospital system every 90 days. Medical visits every 90 days served as a proxy for medication refill data. A case-crossover study design was used to assess effects of co-prescribing antidepressants with AEDs on seizure activity. In this design, cases served as their own controls using 2:1 matching. Analyses involved generalized estimating equations (GEE) to account for repeated measures with differing time periods of antidepressant medication use: 3 months and 6 weeks. We estimated the odds of seizure activity after adjusting for gender, age, and marital status.

Results: Overall, nearly half of the patients were male (48%), and the majority were single (62%) with a mean age of 48 years (SD=16.5). In this sample, there is a low proportion of patients who were prescribed antidepressants (5%). The results of the GEE model suggest that the odds of having a seizure are nearly half for patients who have been co-prescribed an antidepressant with an AED for 6 weeks (OR=0.44; 95%CI: 0.42, 0.45) after adjusting for age, gender, and marital status. The odds of seizure activity further decrease for those who have been co-prescribed the medications for 3 months (OR=0.39; 95%CI: 0.38, 0.40).

Conclusions: Antidepressants, when co-prescribed with AEDs, may have a protective effect on seizure activity. This result suggests that treating depression among PWE decreases seizure activity. However, this result may be a result of selection bias conditioning on hospital system visits every 90 days, assuming that prescriptions are being filled regularly. Additionally, this study had access to medical visits of one hospital system, and is missing data on all other medical visits outside of the system. These results present opportunities for future research and interventions to reduce seizure frequency.

4198 | Cutaneous adverse drug reactions to antiretroviral therapy among HIV-infected patients in a Nigerian teaching hospital

Abdulwasiu A. Busari[1], Kazeem A. Oshikoya[2], Divine-Favour C. Imoh[1] and Ibrahim A. Oreagba[1]

[1]*College of Medicine, University of Lagos, Lagos, Nigeria;* [2]*Lagos State University College of Medicine, Ikeja, Lagos, Nigeria*

Background: Cutaneous adverse drug reactions (CADRs) are common in HIV infected patients than the general population. Antiretroviral therapy (ART) induced CADR are associated with increasing morbidity and mortality. Despite the benefit of ART, they are limited by CADRs, especially at initiation of therapy.

Objectives: The study aimed to determine the prevalence, pattern of and factors predicting CADRs among HIV-infected patients receiving ART at the Lagos University Teaching Hospital (LUTH) in Nigeria.

Methods: A total of 450 HIV-infected patients on ARTs and attending APIN (AIDS Preventions Initiative in Nigeria) clinic at LUTH were studied over 3 months. Data were captured with a self-designed pro forma. Demographics clinical details, prescribed ART, as well as pattern and severity of CADRs experienced by the patients were extracted. Data were analyzed using SPSS version 20.0. The demographic, Univariate analysis of the variables were compared for patients with and without CADRs. Covariates predicting CADR were determined using multiple logistic regression. Any p value <0.05 was considered to be statistically significantly.

Results: Of the 450 patients evaluated, (121: 26.9%) were male. The median (interquartile range) age was 40 (36-48.65) years. CADRs was reported in (22;5.4%) patients, which were mild (32%), moderate (52%), and severe (8%). The pattern of CADR reported include maculopapular rash (55.3%) urticarial rash (19.6%), fixed drug eruption (7.1%), and angioedema (3.5%). Steven Johnsons syndrome (SJS) (7.1%) and Toxic Epidermal Necrolysis (TEN) (3.5%) were the severe forms of CADRs reported. Suspected drugs for the CADRs are nevirapine (80.4%) zidovudine (7.1%), cotrimoxazole (1.8%), and isoniazid (1.8%). Female gender (OR=0.1, CI =0.03-0.72, p= 0.017) and use of nevirapine (OR=10.2, CI = 4.1-25.5, p=0.001) were the independent risk factors for CADRs.

Conclusions: Use of nevirapine was associated with CADR, necessitating a shift from nevirapine based to dolutegravir based ART. A higher risk of CADRs in female patients would require monitoring of ART use in this gender.

4240 | (In) appropriate LAMA prescribing in asthma patients: A cohort analysis (the Alpaca study)

Christina Hoeve[1], Esme Baan[1], Maria de Ridder[1], Leis Demoen[2], Lies Lahousse[1,3], Guy Brusselle[1,2] and Katia Verhamme[1,2]

[1]*Erasmus University Medical Center, Rotterdam, Netherlands;* [2]*Ghent University Hospital, Ghent, Belgium;* [3]*Ghent University, Ghent, Belgium*

Background: Although long-acting muscarinic antagonists (LAMA) are only indicated as add-on therapy in asthmatic patients, there are concerns of monotherapy use.

Objectives: To study the prevalence of LAMA monotherapy and its potential association with severe asthma exacerbations (SAE) in patients with asthma.

Methods: A cohort study (2007-2017) in the IPCI primary care database, in asthma patients aged 6-50, using LAMA during follow-up. Respiratory prescriptions were retrieved from the electronic medical records based on ATC code. Asthma treatment periods were categorized as LAMA mono, double (LAMA+ICS), or triple therapy (LAMA

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

+ICS+LABA). Patients characteristics (age, sex, history of exacerbations, and comorbidities) were collected at the start of each treatment period. A Poisson regression analysis was performed to calculate the relative rate (RR) of SAE, adjusting for patient characteristics.

Results: From a total of 66,508 asthma patients, 1,238 (1.9%) LAMA users were identified, with a median age of 41 years and 65.9% females. From a total of 3,596 LAMA treatment periods, 1,390 (38.7%) were considered LAMA mono therapy, 553 (15.4%) double therapy and 1,653 (46.0%) triple therapy. In all patients using LAMA, the RR of SAE during monotherapy compared to double therapy was 1.6 (p=0.42). When excluding patients who ever used triple therapy the RR increased to 5.7 (p=0.02).

Conclusions: This observational study shows that LAMA is frequently prescribed as monotherapy (i.e. without concurrent ICS) which is associated with an increased risk of exacerbations. This emphasizes the need to check for ICS use when prescribing LAMA to asthmatic patients.

4265 | Identification of clinical cases to educate pharmacists on medication-related problems leading to hospital readmissions after discharge

Selma En-nasery - de Heer[1,2], Elien B. Uitvlugt[3], Patricia M.L.A. van den Bemt[4], Bart J.F. van den Bemt[5,6], Pierre M. Bet[1,2], Eleonora L. Swart[1], Fatma Karapinar[7] and Jacqueline G. Hugtenburg[1,2]

[1]Amsterdam UMC, VU University Medical Center, Amsterdam, Netherlands; [2]VU University Medical Center, Amsterdam, Netherlands; [3]OLVG Hospital, Amsterdam, Netherlands; [4]University Medical Center Groningen, Groningen, Netherlands; [5]Sint Maartenskliniek, Nijmegen, Netherlands; [6]Radboudumc, Nijmegen, Netherlands; [7]OLVG, Amsterdam, Netherlands

Background: Despite the introduction of various measurements aimed at facilitating correct prescribing, the number of medication-related admissions in the Netherlands is not declining. Therefore, it is important to identify medication-related readmissions and educate pharmacists on medication-related problems (MRPs) that may occur after hospital discharge. Cases regarding preventable hospital readmissions could give insight to pharmacists to identify MRPs around hospital discharge.

Objectives: To select cases of preventable medication related readmissions due to transitions in care, that can be used to train pharmacists to possibly prevent MRPs, improve the information transfer between healthcare providers and to adequately inform patients on their medication and its correct use.

Methods: Data of 117 medication-related readmissions were collected and discussed by the research team. 16 potentially preventable re-admissions were selected and assessed in a two round Delphi procedure with nine experts. In the first round the preventability of the medication-related readmissions and their suitability for educational purposes were assessed. Experts also provided written comments on their decision. Consensus was defined as more than 75% agreement between the experts. In the second round, experts gave their opinion on cases for which consensus had not yet been achieved.

Results: After the first round, eight cases were considered suitable as educational material. Four cases were resubmitted. After the second round, two additional cases were also considered suitable after changes. The ten selected cases represent a number of MRPs, such as a prescription error, an error upon discharge and the error of incorrectly continued use after discharge.

Case presentation example: *An 89-year-old woman with a history of insulin dependent diabetes mellitus type II was initially admitted with hypoglycemia. During the hospital stay the patient's insulin dosage was lowered and she was discharged. Within three weeks the patient was readmitted with low consciousness and transpiration. The patient was diagnosed with severe hypoglycemia, caused by administering too much insulin. It appeared that the medication change during the patient's initial hospital admission was not clear. Therefore, the patient continued her old insulin dosage after initial discharge*.

Conclusions: Ten cases were selected by the Delphi panel and can be used as material to train pharmacists and other healthcare professionals to timely identify MRPs that occur after hospital discharge.

4281 | Impact of medication adherence on mortality and cardiovascular morbidity after acute coronary syndrome: Population-based cohort study

Gerard Sotorra-Figuerola[1,2], Dan Ouchi Vernet[1,2], Rosa Morros[1,2,3] and Maria Giner-Soriano[1,2,3]

[1]Fundació Institut Universitari per a la Recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Barcelona, Spain; [2]Universitat Autònoma de Barcelona, Bellaterra, Cerdanyola del Vallès, Spain; [3]Institut Català de la Salut, Barcelona, Spain

Background: Long-term administration of aspirin, statins, beta-blockers, and angiotensin-converting enzyme inhibitors (ACEI) or angiotensin II receptor blockers (ARB) as a secondary prevention improve survival after an acute coronary syndrome (ACS). The adherence to these four pharmacological groups (study drugs) is crucial after ACS.

Objectives: To assess the relationship between the adherences to the four study drugs for secondary prevention and cardiovascular morbidity and all-cause mortality in patients after a first episode of ACS in both sexes.

Methods: Population-based cohort study of adults admitted to hospital with a first episode of ACS during 2009-2016. The data source was SIDIAP (Information System for research in Primary Care [PC]) database, containing anonymized information from electronic health records in PC (Catalonia, Spain). The composite endpoint included: ACS, ischaemic stroke and all-cause mortality. Proportion days covered (PDC) was used to estimate the medication adherence, classifying the patient into adherents (≥85%) and nonadherents (<85%). Time to composite endpoint was analysed by means of nonparametric Kaplan-Meier curves and log-rank test for group comparison.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 7,152 patients met the inclusion criteria having more than 60 days of follow-up and at least one study drug prescribed. 70.3% were men and the mean age was 70.7 years-old (men: 68.3; women: 76.4). During follow-up (median 2.5 years), 1,139 (22.6%) patients suffered a second ACS, 136 (2.7%) an ischemic stroke and 409 (8.1%) died. For all study drugs, adherent patients had a significant lower probability to have a subsequent cardiovascular event or death than nonadherent patients. Although the observed benefits of being adherent were higher in antiplatelets and statins. In ACEI/ARB and beta-blockers the differences were subtle and disappeared at the end of follow-up. Analysis of adherence to any study drug per sex showed that both men and women had a significant lower probability to suffer a second event or death than nonadherent, although the effect was higher in women.

Conclusions: Adherence to study drugs after a first ACS was associated to lower probability of suffering a new cardiovascular event or death. This effect was higher for antiplatelets and statins. The differences between sexes were slight, although nonadherent women had more probability to suffer a second event or death than men, particularly, at the end of follow-up, probably because women were older.

4293 | Evidence based practice in supplying of over the counter medicines in community pharmacies: A mixed methods study

Nada Alobaid[1], Hind Aboheimed[2], Areej Alhumsi[2], Ghada Aboheimed[2], Nouf Aloudah[2] and Noura Aboheimed[2]

[1]Saudi Food and Drug Authority, Riyadh, Saudi Arabia; [2]Kind Saud University, Riyadh, Saudi Arabia

Background: Despite current studies that showed community pharmacists had a positive attitude toward evidence based medicine (EBM) supply of OTC medicines, there is a lack in EBM practice in community pharmacies.

Objectives: To assess and explore EBM in supplying OTC medicines for three minor ailments: diarrhea, cough, common cold by community pharmacists in Saudi Arabia.

Methods: The study used a mixed methods approach consisted of two parts. The quantitative study which used a mystery shopper approach for 214 randomly selected pharmacies from Riyadh region using 14 questions-Quest Scholar MAC checklist to examine community pharmacists' application of EBM. Secondly, the qualitative study, which encompassed three focus groups with 13 pharmacists from different community practice settings to explore factors affecting EBM practice in supplying OTC medicines from the pharmacist's point of view using theoretical underpinning, designed topic guide.

Results: The analysis showed that only 40% of pharmacists supplied OTC medicines according to EBM. Additionally, logistic regression analysis showed that only two questions asked predicted the correct supply of OTC medicines (Q1:describe your symptoms, Q2:when did the symptoms start?). The two questions has significant p values: 0.022 and 0.023 respectively. The focus groups analysis has identified a range of 29 factors, some were facilitators such as established patient-pharmacist relationship, some were barriers such as conflicts between available evidence, and some were acting as both facilitator and barrier such as patient' awareness and education.

Conclusions: Given the fact that OTC supply is a core function for pharmacists, this study showed a low OTC supply according to EBM. Furthermore, this study identifies several factors explaining this phenomenon. Targeting factors identified in this study might help change this behavior and decrease unwanted events.

4351 | Prediction of COPD treatment nonadherence using real world medicare data

Tham T. Le[1], Danya M. Qato[1,2], Margrét Bjarnadóttir[3], Larry Magder[2], Zafar Zafari[1] and Linda Simoni-Wastila[1]

[1]University of Maryland School of Pharmacy, Baltimore, MD; [2]University of Maryland School of Medicine, Baltimore, MD; [3]University of Maryland College Park, College Park, MD

Background: Nonadherence to treatments for chronic obstructive pulmonary disease (COPD) increases exacerbation risks. Predicting future nonadherence facilitates the identification of nonadherent patients for risk stratification or intervention.

Objectives: To validate prediction models of future nonadherence to COPD maintenance medications in older adults with COPD.

Methods: Design: A retrospective cohort using a 5% sample of Medicare claims from 1/1/2012 to 12/31/2014. **Settings:** This study included beneficiaries: (1) aged > 65 years; (2) had a new COPD diagnosis (index) in 2013; (3) had at least one prescription for COPD maintenance medications within a month from the index; and (4) had 12 months pre- and 12 months post- index continuous enrollment in Parts A, B, and D. We excluded individuals with Medicare Advantage or those who died during the 12-month follow-up. **Predictors:** Measured baseline predictors in the 12 months pre-index included sociodemographic factors, 44 comorbidities (binary), 44 medication use (binary), and proxies for COPD severity (oxygen supplementation and COPD hospitalization). **Main Outcomes:** The primary outcome was nonadherence (defined as proportion of days covered of < 70%) to any inhaled COPD maintenance medications (corticosteroids, long-acting β-agonists, and long-acting anticholinergics, alone or in combination) measured using Part D claims in the 12 months post-index. **Statistical analyses:** The data were randomly divided into the training (70%) and validation (30%) sets. We implemented logistic regression and used positive predictive values (PPV) and Area Under the Curve (AUC) to evaluate prediction performance.

Results: Of 4,416 eligible beneficiaries, 65.4% were female, 85.8% were white, and had a mean age of 77 years. About 32% (n=1,455) of beneficiaries adhered to the COPD maintenance medications. In the validation set: AUC=0.67, sensitivity=93%, and PPV=69% (applying a cut-off=0.5). Using a more conservative cut-off of 0.9 resulted in a PPV of 82% and a sensitivity of 51%. Significant predictors of nonadherence were baseline asthma, COPD hospitalization, and medication use (asthma medications, opioids, anxiolytics, and anticoagulants).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: The logistic regression model shows potential to identify nonadherent patients for intervention, which can label 50% of nonadherent patients with a PPV of >80%. That said, upon test results, less than one out of five patients would mistakenly receive the adherence intervention. For our next steps we will apply other prediction algorithms in a machine learning approach using more years of data.

4360 | Personalized comparisons of flare rates after hydroxychloroquine tapering or discontinuation in systemic lupus

Celline C. Almeida-Brasil[1], Christian A. Pineau[2], Evelyne Vinet[1], John G. Hanly[3], Christine A. Peschken[4], Ann E. Clarke[5], Paul R. Fortin[6], Michal Abrahamowicz[1] and Sasha Bernatsky[1]

[1]McGill University, Montreal, QC, Canada; [2]McGill University Health Centre, Montreal, QC, Canada; [3]Dalhousie University, Halifax, NS, Canada; [4]University of Manitoba, Winnipeg, MB, Canada; [5]University of Calgary, Calgary, AB, Canada; [6]Université Laval, Quebec City, QC, Canada

Background: Hydroxychloroquine (HCQ) is a cornerstone treatment for several autoimmune diseases including Systemic Lupus (SLE). Given unclear risk/benefits in long-term use, patients and physicians struggle with decisions about tapering/stopping HCQ. Although some patients may do well after reducing therapy, others will have potentially life-threatening complications related to SLE flares.

Objectives: To identify factors associated with SLE flare risk after HCQ is tapered or discontinued, and to compare flare rates among high-risk subgroups.

Methods: We analyzed prospective data from 5 Canadian cohorts of SLE patients treated with HCQ, using annual study visits between 1999-2019. We assessed patients from date of HCQ tapering (cohort 1) or discontinuation (cohort 2) until disease flare, defined by therapy augmentation, increase of ≥4 points in the SLE Disease Activity Index-2000 (SLEDAI-2K) or hospitalization for SLE. Multivariable Cox regression was used to identify demographic and clinical factors associated with time to first flare. We compared unadjusted flare rates and 95% CIs stratified by the risk factors. A third cohort of patients remaining on HCQ was used as a control, to assess if the same factors influenced flare rates even when HCQ dose was unchanged.

Results: In cohort 1 (N=398, 731.2 person-years), multivariable Cox analyses suggested that non-Caucasians (i.e., Asians, Blacks or First-Nations), patients with active SLE (SLEDAI-2K≥4) and those on prednisone at the time HCQ was tapered had a greater flare risk. Patients with ≥1 of these characteristics at the time of HCQ taper had a higher flare rate (4.2/1000 person-years, 95% CI 3.6, 4.9) than patients without any such characteristics (2.8, 95% CI 2.3, 3.4). In cohort 2 (N=395, 788.9 person-years), flare risk after HCQ discontinuation was greater for non-Caucasians and those with SLE onset at age ≤25 years. Patients belonging to one or both of these subgroups had an increased flare rate after HCQ discontinuation (4.2/1000 person-years, 95% CI 3.5, 5.0) versus those without these factors (2.2, 95% CI 1.8, 2.6). In patients remaining on HCQ (N=621), there was a trend towards higher flare rates in patients with risk factors (2.8/1000 person-years, 95% CI 2.5, 3.3) versus those without (1.9, 95% CI 1.4, 2.6), though 95% CIs overlapped.

Conclusions: Non-Caucasians, patients with SLE onset at age ≤25, those with more active SLE and/or using prednisone have more flares after HCQ tapering or discontinuation. Being aware of these factors may help physicians and patients in personalizing decisions regarding HCQ de-escalation or maintenance.

4408 | Data sources publicly available in Brazil for drug utilization research

Lisiane F. Leal[1], Claudia G.S. Osorio-de-Castro[2], Felipe Ferre[3], Ivan R. Zimmermann[4], Daniel M. Mota[5], Izabela Fulone[6], Marta Mde F. Fonteles[7], Andre O. Baldoni[8], Monique Elseviers[9] and Luciane C. Lopes[6]

[1]McGill University, Montréal, QC, Canada; [2]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil; [3]Universidade Federal de Minas Gerais, Minas Gerais, Brazil; [4]Ministry of Health, Brasilia, Brazil; [5]Brazilian Health Regulatory Agency, Brasilia, Brazil; [6]University of Sorocaba, Sorocaba, Brazil; [7]Federal University of Ceara, Ceara, Brazil; [8]Federal University of Sao Joao Del-Rei, Sao Joao Del-Rei, Brazil; [9]Ghent University, Ghent, Belgium

Background: The use of large databases and its limitations for Drug Utilization Research (DUR) is not a new topic leading to discussions in several countries. In Brazil, studies to map the accessibility, feasibility and reliability of health databases to conduct DUR are still missing.

Objectives: To identify and catalogue publicly available data sources for DUR in Brazil. To characterize the type of data sources prone to be used for DUR.

Methods: The present study is part of the project entitled 'Publicly Available Data Sources for Drug Utilization Research in Latin American (LatAm) countries. In Brazil, a network of Brazilian health experts was defined. The process of searching, screening and selection of the data sources was made in three phases. Further, they were characterized according to their accessibility, geographic granularity, setting, type of data (aggregate or individual-level) and years of coverage. A general search for publications for each data source was conducted.

Results: A total of 55 data sources were identified. We excluded 17 (30.9%) data sources in which medication information was not available and 4 data sources were grouped into 2 different data sources, according to the type of data provided. Finally, 36 (65.4%) data sources were included for characterization. In the qualitative analysis, 10 (27.8%) were classified as Publicly and conveniently accessible online of which 9 (90.9%) the custodian was the Brazilian Ministry of Health through the Health Informatics Department of the Brazilian Ministry of Health (DATASUS). All data sources publicly available online provided national information, at least one year of coverage and presented both individual and aggregated-data levels. At least one scientific publication was found for each one, with exception of one data source which is an electronic system of purchases and contracts.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: In Brazil, DUR using publicly available data sources is feasible. National administrative health databases are provided through the DATASUS and give information regarding the population covered by the National Health System (SUS). Although available, data are not easily managed. Reliability for using Brazilian data for DUR will require further work.

4425 | Assessing the feasibility of evaluating tacrolimus use after solid organ transplantation in sentinel distributed database

Mingfeng Zhang[1], Sarah Dutcher[1], Monique Falconer[1], Nicole Haug[2], Zhong Wang[1], Lockwood Taylor[1], Andrew Petrone[2], Sheryl Kluberg[2] and Justin Bohn[2]

[1]U.S. Food and Drug Administration, Silver Spring, MD; [2]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA

Background: Tacrolimus is an immunosuppressive drug for prophylaxis of organ rejection in patients receiving allogeneic kidney, liver or heart transplants. Concerns exist among healthcare providers about the therapeutic equivalence of brand and generic tacrolimus.

Objectives: To capture transplant patients and tacrolimus use in the Sentinel Distributed Database (SDD) to determine the feasibility of future studies on evaluating therapeutic equivalence of tacrolimus products.

Methods: We used data from August 10, 2009 to October 31, 2017 from 17 Data Partners in the SDD. Kidney, heart, and liver transplants were captured by inpatient CPT-4, ICD-9-CM and ICD-10-PCS codes. Transplant recipients were required to have continuous health plan enrollment for at least 12 months prior to inpatient admission and no multiple transplants, no prior transplant or tacrolimus dispensing during this time. We assessed the follow-up time in the SDD from hospital discharge until disenrollment, death, or the end of data availability. We estimated the gap in days between hospital discharge and first tacrolimus dispensing, identified using National Drug Codes (NDCs). For patients with first dispensing ≤30 days after discharge, we evaluated the duration of continuous tacrolimus use and length of gaps between episodes.

Results: We identified 3,655 liver transplants, 27,353 kidney transplants, and 1,586 heart transplants in the SDD, with median follow-up times of 557, 714 and 565 days, respectively. We captured dispensings of oral tacrolimus for 1,403 (38.4%) liver transplants, 4,904 (17.9%) kidney transplants and 477 (30.1%) heart transplants. When restricted to a non-Medicare population, we captured oral tacrolimus dispensings for 1,232 (72.5%) of 1,699 liver transplants, 3,360 (66.1%) of 5,083 kidney transplants, and 387 (64.9%) of 596 heart transplants. The median gap between discharge and first dispensing ranged 2-8 days for all transplant patients and 1-3 days for non-Medicare transplant patients. Among patients who had at least one gap between tacrolimus treatment episodes, the median gaps between the first and second episodes were 15, 20 and 14 days for liver, kidney and heart transplants, respectively.

Conclusions: We captured liver, kidney and heart transplant patients in the SDD, and the majority of them had less than 2 years of follow-up, which may impact the feasibility of evaluating long-term outcomes. We captured dispensings of individual oral tacrolimus products using NDC codes, although the fewer observed dispensings among the Medicare population requires further investigation.

4437 | The prevalence of polypharmacy in the elderly population: A multi-country database study in Europe

Paola Nasuti[1], Marion Bennie[2], Katja Taxis[3], Shruti Menon[1], Julien Trehony[4], Laurence Sophie Jouaville Abrouk[4], Monique Elseviers[5], Elisabetta Poluzzi[6], Catherina Sermet[7], Sean MacBride Stewart[8] and Ingrid Schubert[9]

[1]IQVIA Ltd, London, United Kingdom; [2]Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, United Kingdom; [3]University of Groningen, PharmacoTherapy, Epidemiology and Economics, Groningen, Netherlands; [4]IQVIA Ltd, Paris, France; [5]University of Antwerp, Antwerp, Belgium; [6]University of Bologna, Bologna, Italy; [7]IRDES, Institut de Recherche en Economie de la Santé, Paris, France; [8]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [9]Faculty of Medicine and University Hospital of Cologne, Cologne, Germany

Background: The reported prevalence of polypharmacy in populations aged ≥65 years varies (38% - 65%) across Europe. This is attributable to differences in methodology and lack of consensus on the definition of polypharmacy in terms of number of medications. Most studies used a cut-off value of five. In older people polypharmacy increases the likelihood of potentially inappropriate medications (PIM). Antipsychotics and benzodiazepines (BDZ) are among the most frequently used PIMs. In addition, concerns have been recently raised about the potential overuse of proton pump inhibitors (PPIs) and opioids in this population. There is currently no recent cross-country literature on the prevalence of polypharmacy and use of these medications of special interest in the European elderly population.

Objectives: Estimate the prevalence of polypharmacy and explore the use of PIMs in older people across five European countries.

Methods: A descriptive retrospective study of elderly patients (≥65 years) with at least two GP visits in 2018 collected from nationally representative databases in Belgium (Longitudinal Patient Database [LPD]), France (LPD), Germany (LPD), Italy (LPD), and UK (IQVIA Medical Research Data). The index date was the last GP visit recorded during the study time period (1st January - 31st December 2018). Polypharmacy was defined as ≥5 distinct drug classes (ATC level 3) prescribed in 6 months before/at index date. Drugs known to be used short-term (e.g., antibiotics), irregularly (e.g., dermatologicals), prescribed by specialists (e.g., oncological medication), stoma and dressings were excluded from the analysis. Use of selected PIMs (e.g. BDZ), opioids and PPIs was also explored.

Results: Preliminary results covering France showed that the cohort consisted of 257,020 patients. 55.5% of these patients were female and 58.0% presented polypharmacy. Of the 149,089 patients with polypharmacy, 77.1% were prescribed 5-9 drugs and 22.9% ≥10

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

drugs. The most prescribed classes were analgesics and antipyretics N02B (65.4%), followed by drugs for treatment of peptic ulcer A02B (48.9%) and antithrombotic agents B01A (48.8%). A higher proportion of patients 65-74 yrs (48.9%) was observed vs. 75-84 yrs (35.7%) vs. >84 yrs (15.3%). Exploratory analyses showed that 32.9% of the study cohort was prescribed a PPI and/or a BDZ (14.1%).

Conclusions: The full study due to be completed by June 2020, will allow exploration of differences and similarities in polypharmacy across Europe. Exploratory analyses will potentially identify differences in local policies in regards to prescribing PIMs, PPIs and opioids.

4463 | Instruments to measure medication literacy: A scoping review

Lais L.N. Pantuzza, Elizabeth do Nascimento, Stephanie F. Botelho, Maria Auxiliadora P. Martins and Adriano M.M. Reis
Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Considering that inadequate medication literacy can be associated with a greater risk of medication misuse and adverse drug events, there is a growing demand for valid/reliable tools to estimate its level. Although some tools have been developed, there is currently limited information on how medication literacy can be measured.

Objectives: To systematically review the literature on the instruments available to measure medication literacy.

Methods: The search was carried out in MEDLINE, LILACS, Cochrane, CINAHL, PsycINFO, Embase, Scopus, Web of science, ProQuest Dissertation & Theses Database, Ovid, Brazilian Digital Library of Theses and Dissertations and in the references of the selected studies. Search terms included *medication literacy* and its synonyms. Methodological studies for the development of instruments or observational/experimental studies that used an instrument to measure medication literacy published until December 2019 in English, Portuguese or Spanish were eligible for inclusion.

Results: Fourteen instruments were identified, but four of them were adapted/translated versions. Although the design of the instruments varied substantially, their items were generally based on real-life situations of medication use and on medications props (prescription bottles, auxiliary labels, products, patient medication information sheets or measuring devices). The number of items ranged from 6 to 37. There was great variability in terms of the target population of the instruments since it involved patients and even parents of pre-school children. Six instruments were developed to be administered as an interview, six for self-administration and two for both modes, with administration time ranging from 10 to 22 minutes. All instruments, except one, were evaluated as a single score and none had cut-off points for medication literacy levels. In general, they incorporated only functional literacy and numeracy, focusing on reading comprehension skills, word recognition or numerical abilities.

Conclusions: Although a relatively large number of instruments were identified to measure medication literacy, they generally did not analyze more advanced literacy skills, such as the ability to interpret, use and seek medication-related information and to communicate with healthcare professionals. In addition, the instruments were poorly analyzed in relation to their psychometric characteristics. These limitations prevent the effective identification of approaches to improve literacy skills and establish behavior changes for the proper use of medications.

4512 | Defining potential exposure periods from prescription medical records of nitrates taken on an as-needed basis

Anthony P. Nunes[1,2], Andrew Stewart[3], Alankar Gupta[3], Thomas McGraw[3], Jennifer Song[2] and John D. Seeger[2]
[1]*University of Massachusetts Medical School, Worcester, MA;* [2]*Optum Epidemiology, Boston, MA;* [3]*Sanofi, Boston, MA*

Background: Assessment of the risks and benefits of medications that are taken as needed is complicated in administrative data due to the uncertainty of exposure timing. Relative to pharmacy dispensing, prescription records in electronic health record (EHR) data have increased uncertainty because prescriptions may not be filled or refilled.

Objectives: To assess variability in inter-prescription intervals of as-needed nitrates and to seek to define nitrate possession based on prescription data.

Methods: Using Optum EHR data (2012 to 2016), we identified patients with any nitrate prescription. Inter-prescription interval duration was calculated as the difference between issue dates of consecutive within-patient nitrate prescriptions. Among patients with more than one nitrate prescription on unique days, we used linear regression models to assess the predictive ability of prescription elements to assess time to next prescription. Prescription elements (determinants) included number of refills on the prescription, along with the quantity and days. Models were run overall and within nitrate categories. Distributions of median, 90th percentile and 95th percentile of inter-prescription intervals were evaluated within categories of number of fills, quantity dispensed, days supplied, and total days supplied.

Results: Models explained very little of the variance, suggesting that the duration of exposure to nitrates from prescription data alone is uncertain. To address this uncertainty, we defined three exposure periods based on inter-prescription interval: likely possession (prescription date to the median), uncertain possession (from the median to the 95th percentile), and unlikely possession (beyond the 95th percentile). Generally, the uncertain period was notably longer than the likely possession period. For example, for oral nitrates, the uncertain duration was 164% of the likely duration. This difference was more pronounced for prescriptions with smaller days supplied and/or lower refills.

Conclusions: Pharmacoepidemiological assessments of medications taken on an as-needed basis, such as nitrates, must address uncertainty of exposure periods, and this is particularly important with prescription-based data sources. Creating intervals of likely, uncertain, and unlikely possession based on the inter-prescription intervals within stratum of combinations of refills, quantity dispensed, and days supplied offers an approach.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4521 | Switching of second generation antipsychotics in patients with severe mental disorders: A cohort study

Izabela Fulone, Marcus Tolentino Silva and Luciane Cruz Lopes
University of Sorocaba, Sorocaba, São Paulo, Brazil

Background: Switching antipsychotic therapy is a common clinical practice and can occur due to therapeutic failure and intolerable adverse reactions. Despite this, data on the frequency and types of exchanges are limited.

Objectives: To identify the factors associated with the switching of second generation of antipsychotic (SGA) in patients with severe mental disorders.

Methods: We conducted a retrospective cohort study of outpatients with severe mental disorders, which were taking SGA (clozapine, risperidone, olanzapine, quetiapine, and ziprasidone) and were admitted to a pharmaceutical assistance program during 2008 to 2017 in Brazil. Data were obtained from national database (APAC/SIA). The outcome of interest was the switch of atypical antipsychotics. The association of predisposing factors for switching was analyzed using COX regression and the hazard ratios (HRs), 95% Confidence Interval (CI).

Results: Of the 759,654 patients identified, 50.5% were women, mean age 44 years and had as initial antipsychotic risperidone (33.1%), olanzapine (29.6%), quetiapine (27.7), ziprasidone (5.1%) and clozapine (4.5%). Over the ten years of the study period, 13.2% switched antipsychotics at least once. The main factors associated with the switches were: female sex (HR: 1.09, 95% CI 1.08 - 1.11), adults with age 19-64 years ($p < 0.001$) and initial use of ziprasidone (HR: 2.24, 95% CI 2.16 - 2.32). Ziprasidone had the highest frequency of switches (14/100 patients-year) and clozapine had the lowest frequency of switches (5/100 patient-year).

Conclusions: There are important differences between drugs of SGA which potentially determines the tendency for switching in real-world settings. The switch was seen more among women, adults and using ziprasidone. Clozapine use tended to show lower switches.

4542 | Mapping for pre-existing large-scale observational databases for acute coronary syndrome in China

Meng Su[1], Fuchun Li[2] and Shusen Liu[1]
[1]*Sanofi Medical, Beijing, China;* [2]*Sanofi R&D Trial Operation, Beijing, China*

Background: Ischemic heart disease (with acute coronary syndrome (ACS) as the main type) ranked second in cause of death in China. High quality pre-existing databases are the prerequisite of generating valid and reliable evidence for drug evaluation and health care quality improvement. Yet knowledge about mapping of ACS pre-existing database is scarce in China.

Objectives: We aim to describe the comprehensiveness of large-scale pre-existing databases for ACS in China.

Methods: Registries and cohorts targeting ACS with sample size larger than 1000 were enrolled by searching clinical trial registration websites, PubMed and Medline. Information on basic characteristics, representativeness, in-hospital (15 dimensions) and follow-up data were extracted from methodological articles, latest publications and registration files.

Results: Eighteen registries (72%) and 7 cohorts (28%) were enrolled with median sample size of 8000. Eight studies were classified as national representative (32%), four involved cross-province cooperation (16%) and the rest half (52%, 13/25) were single-center or localized studies. Overall, only 42% of studies (10/24, exclude one that not started) published protocol paper. For in-hospital information (4 studies excluded for no supporting documents available), good availability (at least 75%) was found in dimensions of demographics, clinical presentation, medical history and risk factors, revascularization, diagnostic procedures, lab results, medication use, in-hospital outcome and discharging information, while moderate availability was found in dimensions of imaging (52%, 11/21) and performance measurement (48%, 10/21) and poor in dimensions of bio-sample (19%, 4/21), costing (19%, 4/21), PROs (24%, 5/21), and hospital level information (28%, 6/21). Among the 21 studies had follow-up data, 17 studies (81%) were followed no longer than 12 months, the rest four followed 24 months. 3-point and 4-point MACE (all-cause death, nonfatal MI, ischemic stroke and revascularization) were the most common outcome (86%, 18/21). Moderate availability in outcomes of heart failure (33%, 7/21), readmission (48%, 10/21), bleeding (57%, 12/21) and medication use (43%, 9/21), while few studies collected information on cardiac shock/arrest (14%, 3/21) and costing (5%, 1/21).

Conclusions: Comprehensiveness for information of clinical treatment process was good in ACS registries and cohorts in China. Attention should be raised for information collected for research purposes on economic analysis, long-term follow-up assessment, patient perceptions evaluation and genetic studies.

4565 | Evaluating the performance of a novel urine-based point-of-care assay for assessing prep adherence for HIV prevention

Randy M. Stalter[1], Jared M. Baeten[1], Deborah Donnell[2], Matthew A. Spinelli[3], David V. Glidden[3], Warren C. Rodrigues[4], Guohong Wang[4], Michael Vincent[4], Nelly Mugo[5], Andrew Mujugira[6], Mark A. Marzinke[7], Craig Hendrix[7] and Monica Gandhi[3]
[1]*University of Washington, Seattle, WA;* [2]*Fred Hutchinson Cancer Research Center, Seattle, WA;* [3]*University of California, San Francisco, San Francisco, CA;* [4]*Abbott Rapid Diagnostics, Pomona, CA;* [5]*Kenya Medical Research Institute, Nairobi, Kenya;* [6]*Infectious Diseases Institute, Kampala, Uganda;* [7]*Johns Hopkins University, Baltimore, MD*

Background: Daily use of oral pre-exposure prophylaxis (PrEP) containing tenofovir (TFV) disoproxil fumarate/emtricitabine is highly efficacious for preventing HIV acquisition but adherence remains a challenge among many populations. We developed a first-of-its-kind, point-of-care lateral flow assay (LFA) with high selectivity for TFV in urine that could aid in counseling individuals on PrEP use in real-time.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: Evaluate the performance of the urine TFV LFA for assessing PrEP adherence and predicting HIV protection.

Methods: Data are from a randomly sampled cohort of HIV-negative men and women assigned to active PrEP use and HIV seroconverters in the Partners PrEP Study, a randomized, placebo-controlled PrEP efficacy trial that enrolled HIV serodiscordant couples in Kenya and Uganda. Urine samples collected at regular intervals were tested with the LFA for TFV concentrations ≥1500 ng/mL, the "threshold" associated with recent use in directly-observed-therapy studies. To provide an established daily TFV adherence standard, TFV concentrations were measured in date-matched plasma samples using a validated liquid chromatography-tandem mass spectrometry method. We calculated the LFA's sensitivity and specificity for detecting plasma TFV >40 ng/mL, which is consistent with daily PrEP use. To assess if urine TFV concentrations ≥1500 ng/mL were associated with HIV protection, we used a nested case-control analysis with incidence density sampling where HIV-negative controls were matched to seroconverter cases 35:1 on the month of case's HIV detection. Rate ratios (RR) were estimated using conditional logistic regression, adjusted for sex, baseline age and report of condomless sex at baseline.

Results: We included 241 cohort members and 17 cases, of which 38% and 47% were female, respectively. Of 391 cohort urine samples, 74% had TFV measurements ≥1500 ng/mL. Of 253 plasma samples with TFV >40 ng/mL, 219 had paired urine TFV concentrations ≥1500 ng/mL, for a sensitivity of 87% (95% CI: 82-91%). Of 138 individuals with plasma TFV ≤40 ng/mL, 68 had paired urine TFV <1500 ng/mL for a specificity of 49% (95% CI: 41-58%). In the case-control analysis, having a urine TFV concentration ≥1500 ng/mL per the LFA was associated with a 68% HIV risk reduction (RR: 0.32, 95%: 0.11-0.90).

Conclusions: A urine TFV LFA result above threshold has good sensitivity but limited specificity for daily PrEP adherence (using a plasma TFV benchmark). The LFA result is also associated with HIV protection. This novel point-of-care test has potential to be a valuable tool for supporting PrEP adherence interventions.

4704 | Acceptance of real world data use in evidence-based medicine or decision making by committee members affiliated with the Saudi food and drug authority

Fawaz Alharbi, Atheer Aldayel and Adel Alrwisan
Saudi Food and Drug Authority, Riyadh, Saudi Arabia

Background: The role of real-world data (RWD) and real-world evidence (RWE) in health care and regulatory decisions is expanding.

Objectives: To explore the acceptance of RWD use in evidence-based medicine or decision making in clinical practice among members of committees involved in the regulatory decision-making at the Saudi Food and Drug authority (SFDA).

Methods:

Study design: a cross-sectional online survey comprising eight questions in English language. Study questions included demographics and acceptability of RWD in varying scenarios. Study population: external members of scientific committees (n=88) in Drug sector at SFDA were invited to participate in the survey on November 2019 through email, then followed by two reminders for non-respondents. Statistical analysis: a descriptive analysis (frequencies with percentages) of the study items.

Results: A total of 45 participants completed the survey (response rate 51%). The participants were mostly physicians (51%) and pharmacists (40%). The majority of respondents (73%) have some formal training in epidemiology. The vast majority of participants (82.2%) responded that they would use observational studies and to a lower extent (66.7%) published case report or case series, as sources of evidence for demonstrating post-marketing safety and adverse events of medications in clinical practice if a conventional randomized clinical trial were not available. On the other hand, 69% of participants stated that they would rely on observational studies to examine the effectiveness of medicines. Participants rated safety (91.1%) and effectiveness (88.9%) as the most relevant types of evidence generated from RWD. 82% of participants considered electronic health records and governmental data as a credible and useful source for RWD.

Conclusions: Our study shows that the physicians and pharmacists involved in the regulatory-decision making had a general acceptance of using RWD in evaluating outcomes of medication use.

4710 | Assessing the feasibility of leveraging healthcare databases to conduct cross-national comparisons of opioid utilisation

Teng-Chou Chen[1], Björn Wettermark[2], Douglas Steinke[1], Gillian Caughey[3], Mina Tadrous[4], Veronika Wirtz[5] and Li-Chia Chen[1]
[1]Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom; [2]Department of Pharmacy, Uppsala University, Uppsala, Sweden; [3]Registry of Senior Australians, South Australian Health and Medical Research Institute and Division of Health Sciences, University of South Australia, Adelaide, Australia; [4]Women's College Hospital, Toronto, ON, Canada; [5]School of Public Health, Boston University, Boston, MA

Background: The disproportional use of opioids globally is a public health problem as it not only resulted in suboptimal pain management but increased risk of harms and substance misuse. Globally, jurisdictions have tackled this issue differently and a cross-national comparison (CNC) study would allow important determinants to develop future policies. However, little is known about the accessibility and validity of information included in healthcare databases across regions.

Objectives: This study aimed to identify the feasibility of using healthcare databases to conduct a CNC study on opioid utilisation.

Methods: A cross-sectional survey was launched in March 2018 and included participants by purposeful and snowball sampling up to November 2018. Experts with interests in CNC studies comparing

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

opioid utilisation in the 2017 Drug Utilisation Research Special Interest Group (SIG) of the International Society of Pharmacoepidemiology were invited. A face validated electronic survey questionnaire was used to collect information related to database characteristics, medicine information and linkage information of each aggregate-level dataset (AD) and individual patient-level dataset (IPD). Descriptive statistics were applied to present the frequency of answers for each item in the survey questionnaire.

Results: Overall, participants from 22 geographical regions reported 20 ADs and 20 IPDs globally. The majority of ADs were established for claims/pharmacy dispensing purposes (n=15), and most of the 20 IPDs were electronic health records (n=7) or built for claims purposes (n=13). Most of the 20 ADs are publicly accessible without additional charge (n=14), but only 5 IPDs can be accessed without additional charge. Although 18 ADs include information from primary care settings, only 11 of the 18 ADs can obtain information from secondary care settings. Substance name, strength, formulation and the number of items dispensed are available from 18 ADs and 17 IPDs, but only 6 ADs can link observations to additional data sources. There were 15 IPDs that included patients' demographic characteristics and diagnosis records or could be retrieved from linkage databases.

Conclusions: The majority of ADs could be used to report opioid utilisation at a primary care setting, and IPDs with linkage databases should be applied to identify potential determinants and relative clinical outcomes associated with opioid use across geographic regions. Further studies would explore the differences which cannot be identified from the database such as prescribing policies between countries.

4798 | Non antibiotic medication use in children in Indonesia

Jarir At Thobari[1], Cahya Dewi Satria[1], Yohanes Ridora[1], Jullie Bines[2] and Yati Soenarto[1]

[1]Faculty of Medicine, Publich Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; [2]Murdoch Children's Research Institute, University of Melbourne, Melbourne, Indonesia

Background: Rational medication use for treatment is mandatory, particularly in children as they are vulnerable to possible hazards of drugs. Understanding the medication use pattern is of importance to identify the problems of drug therapy and to improve the appropriate use of medication among this population.

Objectives: This study is to describe all non-antibiotic medications used in children between age 0-18 months in Indonesia

Methods: A post-hoc study of the RV3-BB Phase IIb trial which was conducted in Indonesia during January 2013 to July 2016. Any concomitant medication use and health events among 1621 trial participants during the 18 months of follow-up were documented. Information on medication use included the frequency, formulation, indication, duration of usage, number of regimens, medication types, and therapeutic classes.

Results: The majority of study participants (N=1333/1621; 82.2%) used at least one non-antibiotic medication for treatment during the 18-month observation period. A total of 7586 medication uses were recorded, mostly in the oral formulation (90.5%). Of all illnesses recorded, 24.7% were treated with a single drug regimen of non-antibiotic medication. The most common therapeutic classes used were analgesics/antipyretics (30.1%), antihistamines for systemic use (17.4%), cough and cold preparations (13.5%), vitamins (8.6%), and antidiarrheals (6.6%). The main medication types used were paracetamol (29.9%), chlorpheniramine (16.8%), guaifenesin (8.9%), zinc (4.6%), and ambroxol (4.1%). Respiratory system disorder was the most common reason for medication use (51.9%), followed by gastrointestinal disorders (19.2%), pyrexia (16.9%), and skin disorders (7.0%).

Conclusions: A large number of children were exposed to at least one medication during their early life, including those where evidence of efficacy and safety in a pediatric population is lacking. This supports the need for further research on pediatric drug therapy to improve the appropriate use of medication in this population.

4845 | Linking regional administrative data with an hospital pathology registry in Italy to describe first-line pharmacotherapy of non-resectable non-small cell lung cancer in 2009-2017

Andrea Spini[1], Giuseppe Roberto[2], Cristiana Bellan[3], Alessandra Pascucci[3], Pietro Rosellini[1], Adele Caldarella[4], Alessandro Barchielli[4], Sandra Donnini[5], Folco Furiesi[3], Lorenzo Leoncini[3], Silvano Giorgi[3], Claudia Bartolini[2], Marco Zappa[4], Marina Ziche[5], Francesco Salvo[1] and Rosa Gini[2]

[1]University of Bordeaux, Bordeaux, France; [2]Agenzia Regionale di Sanità della Toscana, Firenze, Italy; [3]Azienda Ospedaliera Universitaria Senese, Siena, Italy; [4]Istituto per lo Studio, la Prevenzione e la Rete Oncologica, Firenze, Italy; [5]Università di Siena, Siena, Italy

Background: During the last decade, treatment guidelines for advanced stage non-resectable *non-small cell lung cancer* (NSCLC) have rapidly changed mainly due to the introduction of new drugs, as target-therapies (TT) and immunotherapies (IT).

Objectives: To describe the first-line pharmacotherapy in non-resectable NSCLC patients between 2009 and 2017 at the University Hospital of Siena (UHS), a city in Tuscany (Italy).

Methods: Patients with a NSCLC diagnosis recorded in the pathology registry (PR) of UHS in 2009-2017 were identified through SNOMED codes and free text keywords and validated manually by two independent reviewers, based on PR free text. Patients were linked to administrative healthcare database (AHD) of Tuscany. The PR record date was considered as the index date (ID). Patients with a lung surgery recorded in AHD up to 6 months before or after ID were excluded. First-line pharmacotherapy was described using AHD: in particular, records of *Outpatient Drug Dispensings* (ODD) and *Hospital Discharge Records* (HDR) were used. While HDR recorded unspecified chemo- (uCT), monoclonal antibody-based therapy (uMAB) or radiotherapy (RT), ODD recorded drug ATC codes up to the fifth level. Using ODD and HDR, patients were classified according to the first-line treatment received during 6 months following ID: standard chemotherapy (CT), TT, IT, uCT, uMAB, RT, no drugs (ND), or death within six months with

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

no drug treatment (DnoT). Two study periods were considered based on patients' ID: 2009-2013 and 2014-2017.

Results: A total of 831 validated, advanced NSCLC cases were identified in the two study periods: 431 and 400, respectively. Overall, according to ODD and HDR, DnoT patients were about 20% while ND were about 10%. Around 45% of patients received CT or uCT. Patients that received a TT were 4.4% (n=19) in 2009-2013 and 9% (n=36) in 2014-2017. Among TT patients, those who performed an EGFR test increased from 58% in 2009-2013 to 92% in 2014-2017. During the whole study period, the most frequently used TT were gefitinib (n=22, 2.6% of the study cohort) and erlotinib (n=21, 2.5%). Three patients received IT in 2014-2017 (nivolumab n=2; pembrolizumab n=1).

Conclusions: At the UHS, in 2014-2017 use of innovative drugs for the first-line pharmacotherapy of patients with non-resectable NSCLC has increased when compared to 2009-2013. Selective EGFR tirosin-kinase inhibitors, such as gefitinib and erlotinib, were increasingly chosen based on tests for the molecular characterization of the tumor.

4849 | Drug utilization study of the medicinal combination product conjugated oestrogens/bazedoxifene in the European Union

Dorothea von Bredow[1], Margarita Shlaen[1], Vera Frajzyngier[2], Nikolaus Kolb[1], Barbara Thun[1], Leo Russo[3] and Jacco Keja[4]
[1]IQVIA, Munich, Germany; [2]Pfizer, New York City, NY; [3]Pfizer, Collegeville, PA; [4]IQVIA, Amsterdam, Netherlands

Background: Duavive® (conjugated estrogens with bazedoxifene) has been authorized in the EU since 2014 for the treatment of estrogen deficiency symptoms in postmenopausal women for whom treatment with progestin-containing therapy is not appropriate. This drug utilization study was designed to collect real-world data on use of Duavive and was a commitment to the European Medicines Agency.

Objectives: To describe 1) characteristics of EU patients initiating treatment with either Duavive or oestrogen + progestin hormone replacement therapy (E+P HRT) and 2) Duavive utilization patterns.

Methods: A non-interventional retrospective study was conducted using existing data sources in 6 EU countries (electronic medical records in France, Italy, Spain, UK; longitudinal prescription and cross-sectional databases in Belgium and the Netherlands) from March 2016 to March 2019. Age ≤45 was used as a proxy for premenopausal status in the analysis of potential off-label use.

Results: The numbers of Duavive initiators/ E+P HRT users in the longitudinal databases 3 years after Duavive launch were 11/ 29,799 in the UK, 22/ 29,047 in France, 73/ 2,573 in Spain, 177/ 76,550 in the Netherlands, 223/ 6,288 in Italy and 480/ 57,059 in Belgium. The majority of Duavive users were aged ≥50 years, ranging from 55% (UK) to 93% (Belgium); the range for E+P HRT users ≥50 years was 42% (Spain) to 91% (Belgium). Oestrogen deficiency symptoms were recorded in 49% (Spain) to 91% (Belgium) of Duavive users. Potential off-label use of Duavive ranged from 9% (France) to 29% (Spain) of patients and was primarily comprised of use in women ≤45 years of age. These women may have been postmenopausal and using Duavive in accordance with the label indication. Other evidence for potential off-label use included diagnostic codes for osteoporosis (0% in Belgium and France to 5% in Italy and Spain), hypersensitivity (1% in Italy and Spain), concomitant prescriptions of selective estrogen receptor modulators (SERMs; 2% and 7% in Belgium and the Netherlands), prescription of a non-approved dose (2% in Italy and the Netherlands), and malignancy related to oestrogens (<1% in Italy and 1% in Spain). In Belgium and in the Netherlands 4% and 5% of patients (respectively) were >75 years of age; 3% of patients in Belgium, 1% in the Netherlands and <1% in Italy were documented as male.

Conclusions: Overall, Duavive was prescribed to the indicated population and at the dosage recommended in the Summary of Product Characteristics.

4870 | Outpatient antibiotic use in Chinese pregnant women

Houyu Zhao[1], Jiaming Bian[2] and Siyan Zhan[1]
[1]Peking University, Beijing, China; [2]The 7th Medical Center of the Chinese PLA General Hospital, Beijing, China

Background: Antibiotic use in pregnant women is rarely described in China.

Objectives: To estimate the outpatient antibiotic prescription rates for pregnant women in China.

Methods: A data of 4912416 outpatient visits of pregnant women from 128 hospitals in 28 provinces of Mainland China from October 2014 to April 2018 were analyzed. Antibiotic prescription rates by hospital level, age group, and trimester of pregnancy were estimated and reported. The 95% confidence intervals (CIs) were estimated using the Clopper-Pearson Exact method.

Results: Among the 4912416 outpatient visits of pregnant women, 3.45% (95% CI, 3.43% - 3.46%) were prescribed at least one antibiotic. The percentages of antibiotic prescriptions for pregnant women were 8.39% (95% CI, 8.29% - 8.49%) and 3.11% (95% CI, 3.09% - 3.12%) in Chinese secondary and tertiary hospitals, respectively. Among pregnant women under 18 years old, 12.98% (95% CI, 12.32% - 13.66%) of outpatient visits were prescribed antibiotics, while only 2.42% (95% CI, 2.40% - 2.44%) of outpatient visits of pregnant women aged 26-30 years ended with antibiotics. In addition, antibiotic prescription rates varied much among different trimesters of pregnancy, which were 9.09% (95% CI, 9.04% - 9.14%) for the women of first trimester of pregnancy and 0.44% (95% CI, 0.43% - 0.46%) for the women of third trimester of pregnancy. However, among all visits with antibiotic prescriptions, 71.64% (95% CI, 71.33% - 71.95%) had no clear indication and thus might be inappropriate.

Conclusions: Approximately 3.5% of pregnant women received antibiotic prescriptions, while a large proportion of which might be inappropriate.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4896 | Characterizing concurrent use of gabapentin with opioid analgesics among Kentucky residents with long-term opioid prescriptions, 2018

GYeon Oh, Svetla Slavova and Patricia R. Freeman
University of Kentucky, Lexington, KY

Background: Gabapentin is commonly used for neuropathic pain. Although studies have shown limited effectiveness of gabapentin for other types of chronic pain, its use has increased over the past decade, due in part to the increased scrutiny of opioid analgesic (OA) prescribing and the need for non-opioid pain management strategies. Recent studies have documented increased opioid-related risk when gabapentin is used concurrently with OA, similar to that previously reported for use of OA and benzodiazepines (BDZ).

Objectives: The purpose of this study was to characterize the concurrent use of gabapentin, and gabapentin with BDZ, among long-term OA users in Kentucky

Methods: We used 2018 Kentucky All Schedule Prescription Electronic Reporting data for Kentucky residents. Long-term OA use was defined as 90+ consecutive days' supply of OA. Concurrent gabapentin-OA use and gabapentin-OA-BDZ use were defined as 90+ overlapping days and 7+ overlapping days, respectively. We estimated rates of use and concurrent use (per 100 long-term OA users), and reported rate ratios (RR) and 95% confidence intervals (CI) to compare demographic groups and geographical regions. Patents' average daily morphine milligram equivalent (MME) dose was calculated for the overlapping gabapentin-OA period and the period with OA only. Paired t-test was used to test the hypothesis that concurrent use of gabapentin reduces the average daily MME.

Results: The overall rate of concurrent use of gabapentin-OA was 33.5/100, with the highest rates among 45-54 years of age (40.2/100). Rates of concurrent use of gabapentin-OA were significantly higher in females vs. males [RR: 1.07; 95% CI: 1.06-1.09] and Appalachian Kentucky region vs. Central [1.35; 1.33-1.37] or Delta [1.41; 1.38-1.44] regions. One in ten long-term OA users used gabapentin-OA-BDZ concurrently for at least 7 days. The rate of concurrent use of gabapentin-OA-BDZ was highest in the 45-54 years of age (11.9/100). The estimated mean difference in the average daily MME dose among long-term OA users when they used gabapentin concurrently was statistically significant (1.06 MME, p<.0001) but no clinically meaningful reductions.

Conclusions: Given that concurrent use of OAs with gabapentin and gabapentin/BDZ is common, and that there are no clinically meaningful reductions in average daily MME when gabapentin and OAs are concurrently prescribed, a substantial number of individuals may be at heightened risk for opioid-related harm as a result of these drug combinations.

5012 | Persistence with teriparatide treatment in osteoporotic patients: A population-based study using Italian regional databases

Andrealuna Ucciero, Andrea Sarro, Alessandro Pecere and Francesco Barone-Adesi
University of Estern Piedmont, Novara, Italy

Background: Teriparatide (TPT) is an anabolic drug used in the secondary prevention of osteoporotic fragility fractures. It is administered as a daily subcutaneous injection and the treatment is recommended for a maximum of 24 months. The few real-world studies so far conducted suggest an alarming low persistence to TPT, even worse than in other osteoporosis treatments. As non-persistence is one of the most important predictors of treatment failure in osteoporosis, specific research on this topic is needed.

Objectives: Aim of our study was to estimate persistence to TPT in an Italian setting and to investigate possible determinants of non-persistence.

Methods: A retrospective analysis of administrative health databases was conducted in Piedmont, an Italian region with 4.3 million inhabitants. Relevant data were obtained from: i) inhabitant registry, ii) hospital discharge records, iii) drug registry, iv) exemption-from-co-payment registry. Patients who started TPT treatment during the period 2013-2016 were followed for 24 months and were considered as non-persistent if they had gaps in treatment longer than 90 days. Possible determinants of non-persistence were evaluated using non-parametric methods for survival analysis and Multivariable Cox regression models.

Results: During the study period, 2,615 TPT new-users were identified (87% women). Their mean age was 74 years. Average 24-month persistence was 68%. This value increased over time, from 57% in 2013 to 72% in 2016 (Adjusted Hazard Ratio [HR] of non-persistence 2016 vs. 2013: 0.67; 95%CI: 0.54-0.82). Patients aged at least 80 years (HR: 1.17; 95%CI: 1.01-1.36) and those with a Charlson Morbidity Index of 1 or more (HR: 1.35; 95%CI: 1.05-1.73) had a higher risk of non-persistence. Conversely, patients with a previous treatment of vitamin D (HR: 0.68; 95%CI: 0.57-0.81) and other anti-osteoporotic medications (HR: 0.78; 95%CI: 0.68-0.89) were less likely to be non-persistent.

Conclusions: Conclusions: Results from this Italian study suggest a reasonably high persistence to TPT, which steadily increased over time. This is probably due to a greater attention among doctors and patients to the correct use of this medication in recent years. Future research is needed to evaluate the role of early discontinuation of treatment on long term risk of fractures.

5028 | Real world use of opioids in COPD patients

Katia Verhamme[1], Marie Clyncke[2], Lies Lahousse[2], Esme Baan[1] and Guy Brusselle[2]
[1]EMC, Rotterdam, Netherlands; [2]Ghent University, Ghent, Belgium

Background: In COPD, opioids may be considered for relief of cough or pain, or for the palliative treatment of dyspnea.

Objectives: To investigate the real life use of opioids in COPD patients.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A retrospective cohort study was designed to investigate opioid use in COPD patients and in a reference cohort of non-COPD patients using the Dutch Integrated Primary Care Information (IPCI) database. The study period was from 2000-2017. Opioid prescriptions were extracted through an automated search on the ATC code N02A (indication pain) and the ATC code R05DA (indication cough). Opioid use was expressed as the number of patients being prescribed an opioid divided by the follow-up time. Differences in prevalence rates were investigated using Poisson Regression analysis. Differences in patient characteristics between opioid vs. non-opioid treated COPD patients were explored using multivariable logistic regression analysis.

Results: The study population consisted of >1,3 million individuals, 40 years or older. Within this study population, we defined a COPD cohort of 67,990 patients (5,2%) and a reference cohort of non-COPD patients of >1,2 million subjects. The prevalence of opioid prescribing was significantly higher in COPD (206/1,000 person-years [PY]) than in control patients (78/1,000 PY) ($p<0.001$). Opioid use was higher in females and increased by age and calendar time in both cohorts. In both cohorts, use of codeine for pain increased with age, whereas use of codeine for cough decreased from the age of 70 onwards. In COPD patients, independent risk factors for opioid use were age, female sex, cancer (OR_{adj} 1.5; 95% CI 1.5-1.6), lungcancer (OR_{adj} 3.2; 95% CI 2.9-3.4), depression (OR_{adj} 1.6; 95% CI 1.5-1.7), and current smoking (OR_{adj} 1.5; 95% CI 1.4-1.5).

Conclusions: Opioid use was much higher in COPD patients than in non-COPD patients. Female sex, age, smoking and (lung)cancer were important risk factors for opioid use.

5037 | Quality of life in treatment-experienced multiple myeloma patients: A comparative analysis of therapeutic regimens

Jéssica S. Malta[1], Paula L.M. Drummond[1], Lívia P. Silveira[1], Naiane L. Costa[1], Taisa R.L. Machado[1], Roberta M.M. Santos[2], Adriano M.M. Reis[1] and Cristiane A.M. Pádua[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [2]Fundação Ezequiel Dias, Belo Horizonte, Brazil

Background: Multiple myeloma (MM) is a rare, incurable, but a treatment-sensitive hematological cancer, prevalent in elderly. Besides to other age-related factors, therapeutic regimens can promote several functional and Quality of Life (QoL) changes in individuals, such as the adverse effects promoted by thalidomide (Thal).

Objectives: To evaluate the QoL of patients with MM in use of Thal compared to other therapeutic regimens.

Methods: Cross-sectional study conducted with 182 MM patients (≥ 18 years old) attending public and private outpatient services in Belo Horizonte, Brazil from April to November 2019. All patients diagnosed with MM were invited to participate and signed an informed consent form. QoL was measured by interviews using the QoL Questionnaire for MM patients (QLQMY20, Brazilian Portuguese version) of the European Organization for Research and Treatment of Cancer. The score result ranges from 0 to 100. The higher the scores, the better the evaluation of the future perspective and body image domains. Higher scores for disease symptoms and side-effects of treatment represent worst outcomes. Socio-demographic and clinical variables were collected through interview and review of medical charts. Therapeutic regimens have been divided into two groups - Thal and other regimens for comparison. Mean, median standard deviation (SD) and absolute and relative frequencies were estimated and Student's t-test was used to describe continuous variables (level of significance of 5%).

Results: Half of participants was female, aged 66 years old. Most of them were retired (61%) and attended private health clinics (54%). At least one comorbidity and use other drugs than chemotherapeutics was found in 65% and 96% of patients, respectively. Therapeutic regimens comprised combinations of Thal, bortezomib, cyclophosphamide and dexamethasone; 41% patients were not on treated at the time of interview. Among patients who used Thal, 65% are participants who attended public health system. Mean QoL scores were found for patients on treatment with Thal (31%) vs. other therapeutic regimens (28%) - disease symptoms: 15.3 (SD=26.4) vs. 15.6 (SD=19.9); side-effects of treatment: 20.9 (SD=17.3) vs. 21.6 (SD=18.7), body image: 36.9 (SD=42.9) vs. 32 (SD=40.5) and future perspective: 55.4 (SD=29.2) vs. 53.8 (SD=29.5) (p-value >0.05).

Conclusions: Other therapeutic regimens did not show superiority over Thal in promoting QoL in MM patients. This is a positive issue in Brazilian context, since Thal is produced and available by public health system.

5050 | Adherence to immunomodulatory drugs in Brazilian patients with multiple myeloma

Lívia Pena Silveira, Paula Lana de Miranda Drummond, Jéssica Soares Malta, Naiane Lima Costa, Roberta Márcia Marques dos Santos, Taísa Roberta Lopes Machado, Adriano Max Moreira Reis and Cristiane Aparecida Menezes de Pádua

Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Multiple myeloma (MM) is a hematological cancer which manifests mainly in older adults and has no cure. Oral Immunomodulatory drugs (IMID) are widely used in the treatment of MM patients. A primary challenge of oral antineoplastic treatment is ensuring patient adherence. To date, few data are available on IMID adherence in MM patients.

Objectives: To investigate IMID adherence in multiple myeloma patients in Brazilian public and private outpatient services.

Methods: A cross-sectional study was conducted with patients with multiple myeloma (> 18 years old), who have been receiving an IMID for at least 2 months and that consulted outpatient services between April to November 2019. The study was performed in two public and one private outpatient services in a metropolitan city in southeast of Brazil. Socio-demographic (sex, age, self-declared color skin, family income), clinical (disease staging, comorbidities and IMID) and related to health services (outpatient clinics) variables were obtained from interview and medical records. IMID adherence was measured by

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

interview using the Measuring of Treatment Adherence (MTA), developed in Portugal and validated to Brazilian Portuguese. Adherence was classified as adherent (Grade 5-6) or not adherent (Grade 1-4). Descriptive analysis was performed. The internal consistency of the MTA was measured by Cronbach's alpha coefficient. All analyses were performed using SPSS 26.0 software.

Results: A total of 61 patients were included in the study. Half patients were males and attended public outpatient service. Most of them reported to have white skin colored (42.6%), with family income until three minimum wages (54.1%). The mean age was 63.2 years old (SD 10.16). 68,9% had at least one comorbidity. Regarding staging, most patients had a more advanced stage of the MM (41% - DS IIIA and 31.1% ISS II). Thalidomide was the most frequent IMID prescribed in our study (80.3%), followed by lenalidomide and pomalidomide (18.0% and 1.6% respectively) and 83.6% made up to 2 lines of treatment. Regarding IMID adherence, a total of 97.2% were considered adherent according to the questionnaire (grade 5-6). The Cronbach's alpha coefficient was 0.403. Instruments with few items, such as MTA, an alpha value around 0.50 is acceptable.

Conclusions: MM patients attending outpatient services in southeast of Brazil are highly adherent to IMIDs. The development of adherence instruments with better internal consistency is a need to better measurement and understand the adherence of IMIDs in MM patients.

5071 | Effect of an educational program on the medication adherence in adult patients at transition of care

Jimmy Reyes, Carolina Bobadilla, Carlos Silva, Natalia Carrillo, Cristóbal Gutiérrez, Tamara Sandoval and Marcela Jirón
Universidad de Chile, Santiago, Chile

Background: After hospital discharge, patients commonly suffer potentially avoidable adverse outcomes due to poor medication adherence. Despite positive results of patient education to improve adherence, limited information on educational programs focused on the vulnerable transition period from hospital to home is available in developing countries.

Objectives: To assess the effect of an educational program (EP) conducted by pharmacists on medication adherence in adult patients at the transition of care from a teaching hospital to home.

Methods: A prospective pre/post quasi-experimental study was conducted during 5 months period in the Internal Medicine Service (IMS) at a teaching hospital in Santiago, Chile. Patients ≥ 18 years old with drug treatment at admission and signed inform consent form were included. An EP was conducted by 5 pharmacists during patient's hospitalization in the IMS and at discharge. The EP included daily patient and caregiver education on patient's diagnosis, drug therapy, risk of nonadherence, resolve questions and counseling focused on patient's specific needs and problems. At discharge, verbal education and written materials were provided to support patients overcome adherence barriers. Medication adherence and the knowledge of drug treatments were estimated using Morisky-Green scale and a questionnaire of drug therapy (acceptable, unacceptable), respectively, at admission and 30 days after hospitalization

Results: A total of 183 patients were included during the study period. The mean age was 61.3 ±18.8 years, 50.3% were men. A 33.3% of patients had ≥ 12 years of educational level. The main reason of hospital admission was pain (20.2%). Hypertension (49.2%) was the most frequent comorbidity. The mean number of comorbidities was 4.7 ± 1.9 drugs. The EP improved significantly medication adherence in 29.6% (from 46.3% to 75.9%; $p<0.01$). The knowledge of the drug treatments improved 42.3% (from 28.2% to 70.5%; $p<0.01$). Main changes on medication adherence were seen on women, patients with type 2 diabetes, ≥ 5 years of diagnose, and patients with ≥ 12 years of educational level.

Conclusions: A systematic EP based daily contacts with pharmacists during the hospitalization and at discharge could help adult patients to improve significantly adherence and knowledge of drug treatments during the transition of care from a teaching hospital to home. Future studies with a bigger sample and robust design should be conducted to determine the efficacy and safety of this EP.

5160 | Drug use during pregnancy according risk classification and associated factors

Caroline T. de Castro[1], Débora B. Costa[2] and Djanilson B. dos Santos[3]
[1]*Federal University of Bahia, Vitória da Conquista, Brazil;* [2]*Federal University of Ceará, Fortaleza, Brazil;* [3]*Federal University of Recôncavo da Bahia, Santo Antônio de Jesus, Brazil*

Background: The effect of the use of drugs in pregnancy is often unpredictable and can affect both the mother and the foetus.

Objectives: To investigate the factors associated with drug use in pregnancy by risk categories in pregnant women in Santo Antônio de Jesus, Bahia.

Methods: Cross-sectional cohort study with 1,091 pregnant women attended by UBS in the urban area of the municipality between 2012 and 2014. Drug use during pregnancy was classified according to the FDA risk classification system. Socioeconomic, demographic, maternal and health service utilization variables were analysed. Prevalence ratios (PR) and respective 95% confidence intervals (95% CI) were adjusted by Poisson regression with robust error variance.

Results: The prevalence of drug use was more pronounced in risk categories A, B, C, D and X, respectively. The use of safe medication was associated with education, number of prenatal consultations and health problems after data adjustment. The factors associated with the use of risk medication were age greater than 24 years, onset of prenatal care during the first trimester and having any health problems.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: The results of this study are similar to those described in the literature. Investments in continuing vocational education that promote rational antenatal drug use are needed.

Drug Utilization Research -> Quality use of medicines (including indicators and guidelines)

40 | A retrospective audit of the management of childhood acute asthma exacerbation in children: Adherence to global treatment guidelines

Kazeem Adeola Oshikoya[1], Ibrahim Abayomi Ogunyinka[2] and Shallom Ese Imuzie[2]
[1]*Lagos State University College of Medicine, Ikeja, Lagos, Nigeria;* [2]*Usmanu Danfodiyo University, Sokoto, Nigeria*

Background: Adequate management of childhood acute asthma exacerbation requires optimal non-pharmacotherapy and pharmacotherapy. Global asthma guidelines provide critical information and serves as a quick reference decision-support material for clinicians.
Objectives: To evaluate hospital management of childhood acute asthma exacerbation according to global treatment guidelines, and to identify factors that predict short or prolonged observation in the hospital.
Methods: This is a retrospective audit of the management of acute asthma exacerbation in children seen between 01 January 2017 and 31 December 2018 at Usmanu Danfodiyo University Teaching Hospital (UDUTH), Sokoto, Nigeria. Relevant data on demography, asthma triggers and severity, functional and clinical diagnoses, types of controller medications used before and after presentation, non-pharmacotherapy and pharmacotherapy instituted during presentation, duration of observation in the hospital, and treatment outcomes were extracted from the case file of each patient.
Results: All the 119 children presented with mild (88; 73.9%) or moderate (31; 26.1%) acute asthma exacerbation. Their median (interquartile range) age was 5 (2.4-8) years. More males (75; 63.0%) than females (44; 37.0%) presented with acute asthma exacerbation. Cold weather (39; 28.1%) and dust (21; 15.1%) were the predominant triggers. Seretide® (39/75; 52.0%) was the commonest controller medication used by the patients prior to presentation. Nebulized salbutamol (91; 76.5%), in addition to intravenous (44; 57.9%) or oral (32; 42.1%) corticosteroids, was used during hospital treatment. Patients were discharged mostly on short course of oral corticosteroid only (70; 58.8%). A total of 12 out of 14 recommendations were adhered to in over one-half of the patients. The odds of admission for <12 hours were nearly six times higher for patients on systemic corticosteroids.
Conclusions: Management of acute asthma exacerbation was considerably good in accordance with the GINA guidelines and adequate documentation of important details was common in at least one-half of the patients. Reinforcement of institutional guidelines, an adaptation from GINA document, for acute asthma management is suggested to further improve quality care of childhood acute asthma exacerbation.

119 | Potentially inappropriate psychotropic medications use among older adults with psychiatric disorders in the Jazan region, Saudi Arabia

Abdulkarim M. Meraya and Otilia J.F. Banji
College of Pharmacy, Jazan University, Jazan, Saudi Arabia

Background: Over 20% of older adults (>= 60 years) suffer from a mental or neurological disorder, globally. Beers criteria provide a list of psychotropic medications that should be avoided or used with caution in older adults due to the aging process and physiological changes. Evidence on following the criteria and not using potentially inappropriate psychotropic medications (PIPM) in Saudi Arabia, however, is limited.
Objectives: This study aimed at deciphering the pattern of drugs prescribed in older individuals in psychiatric settings, assessing the prevalence of PIPM based on the updated 2015 Beers criteria and discerning polypharmacy in older psychiatric patients.
Methods: This study was a retrospective cross-sectional review conducted on older adults who underwent treatment at the psychiatric hospital in the Jazan region, Saudi Arabia. Electronic medical records of older adults (>=60 years) were reviewed to extract data on clinical factors, demographics and medications used. The outcomes measured were pattern of drug use; in addition, the retrieved data was scrutinized based on Beer's criteria to identify PPIM. Also, the propensity of polypharmacy (prescription of >=2 psychotropic medications) among the elderly was assessed. Multivariable logistic regression was used to assess the relationship between the explanatory variables such as age, sex and psychiatric diagnoses with the use of PPIM.
Results: The final study sample consisted of 1,300 older adults with a psychiatric diagnosis. Of these, 68% were prescribed PIPM. Amitriptyline was the most commonly potentially inappropriate antidepressant followed by maprotiline. The most prescribed potentially inappropriate antipsychotics were chlorpromazine, trifluperazine and risperidone. PIPM use was associated with schizophrenia and anxiety. Furthermore, psychotropic polypharmacy was highly prevalent among the older adults (77.7%).
Conclusions: PIPM use was highly prevalent among older adults with psychiatric diagnoses in Jazan region, Saudi Arabia. Educational programs and interventions are required to increase the awareness about PIPM use among mental health care providers in the Jazan region to minimize risks of unwanted adverse drug reactions among older adults with mental disorders.

2367 | Disposal of leftover medicines: Prevalence and practices among the rural population of Kerala

Jose J. Kochuparambil[1], Akshay Nidha[1] and Aleena Issac[2]
[1]*St. Joseph's College of Pharmacy, Cherthala, Alappey, India;* [2]*Nirmala College of Pharmacy, Muvattupuzha, India*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Leftover medicines in the household is an evolving problem. There are no regulations from the government to safely dispose medicines kept as left over home. Along with this there is a greater number of people accessing medical care and the prescription of medicines also increased resulting in an increased per person consumption of medicines.

Objectives: To determine prevalence of households with leftover medicines and its disposal practices among the rural population of Kerala, India.

Methods: A cross-sectional study was conducted among the rural population of three districts of Kerala. The pre-tested data collection tool used for collecting information on medicine usage and medicine wastage. The houses numbered with multiples of 5 were selected for the study resulting in a total household of 181.

Results: Among the 181 houses surveyed, 93 (51%) households were reported to have left over medicines kept at home. The major reason for medicine left over was found to be symptom relief [42] (45%) and change of prescriber [18] (20%). Among the total families surveyed, 121 (67%) of the families responded that they are disposing their solid medicines along with household waste and in the case of liquid preparations, 98 (54%) were disposing their medicines along with household waste. Some of the responders disposed the medicines as fertilizers for plants.

Conclusions: There is no established system for safe medicine disposal in the community. Even though there are some good practices for collecting the unused medicines by non-profit organisations to re-use it among the needy, they are not standardized. The majority of respondents would support the implementation of a proper system for re-collecting the medicines. Hence, a regulated drug take-back program may result in a reduction in the household medicine wastage.

2398 | Trends in acid suppressant drug prescriptions in primary care in the United Kingdom

Devin Abrahami[1], Emily Gibson McDonald[2], Mireille Schnitzer[3] and Laurent Azoulay[1]

[1]McGill University, Montreal, QC, Canada; [2]McGill University Health Centre, Montreal, QC, Canada; [3]University of Montreal, Montreal, QC, Canada

Background: Proton pump inhibitors (PPIs) and histamine-2 receptor antagonists (H2RAs) are among the most commonly prescribed drugs worldwide. However, there is some evidence that they are being used inappropriately, either in individuals without underlying disease, or for a longer duration than necessary. In light of emerging safety concerns, it has become increasingly important to understand how these drugs are being prescribed in clinical practice.

Objectives: To examine the prescribing patterns of PPIs and H2RAs over time by quantifying prevalence of use in the general population, intensity of use among drug users, and describing persistence patterns among new users.

Methods: Using the United Kingdom Clinical Practice Research Datalink, we defined a cohort of patients prescribed PPIs and H2RAs between January 1990 and December 2018. Annual prescription rates were estimated by dividing the number of patients with at least one prescription by the total population registered in the data. Yearly intensity of use was estimated by dividing the number of prescriptions by the person-years of follow-up, and change in intensity was calculated per decade using negative binomial regression. Finally, Kaplan-Meier curves were used to examine persistence to original treatment course among new users.

Results: PPIs were prescribed to 2,714,785 patients, while H2RAs were prescribed to 855,248 patients. Among new PPI and H2RA users, only 48.4 and 54.1%, respectively, had an approved indication for use. The prevalence of PPI use significantly increased from 1990 to 2018 (0.2 to 14.2%), while the prevalence of H2RA use remained low over the study period (2.5 to 1.9%). Prevalence of use was highest among females and the elderly (at least 60 years old). For every increase in year from 1990 to 1999, the yearly intensity of PPI use increased by 16% (IRR: 1.16, 95% CI: (1.16 to 1.16)), while the intensity of use remained constant from 2000 to 2009 and 2010 to 2018. In contrast, intensity of H2RA use decreased by 11% per year from 1990 to 1999 (IRR: 0.89, 95% CI: 0.89 to 0.90), decreased by 10% per year from 2000 to 2009 (IRR: 0.90, 95% CI: 0.90 to 0.90), and increased by 5% per year from 2010 to 2018 (IRR: 1.05, 95% CI: 1.05 to 1.05). Overall, 38% of PPI and 47% of H2RA users continued using these drugs beyond the one-year duration recommended in treatment guidelines.

Conclusions: This study demonstrates that use of PPIs has been steadily increasing over time, while use of H2RAs remains low. Given the high prevalence of patients who do not have an approved indication for use and the high persistence to treatment, programs which target medication overuse should be considered.

2402 | Utilization of hydroxyprogesterone during the 2nd or/and 3rd trimester among pregnancies with live birth deliveries in the sentinel distributed databases

Huei-Ting Tsai[1], Mayura Shinde[2], Austin Cosgrove[2], Jie Li[1], Christina Chang[1], Christine P. Nguyen[1], Corinne M. Woods[1], Joy Kolonoski[2], Tiffany Siu Woodworth[2] and David Moeny[1]

[1]Food and Drug Administration, Silver Spring, MD; [2]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA

Background: Makena®, hydroxyprogesterone caproate (HPC) injection, is indicated for reducing the risk of preterm birth in women with a singleton pregnancy who had a prior singleton spontaneous preterm birth. The U.S. FDA approved Makena on February 3, 2011 under accelerated approval, contingent upon post-marketing confirmation of clinical benefit, such as improvement in neonatal mortality and morbidity. However, the confirmatory trial completed in 2018 (PROLONG trial), failed to confirm Makena's efficacy. An analysis of drug

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

utilization of HPC, including Makena, in pregnant women was undertaken to inform the landscape of HPC use for deliberations at the FDA's Advisory Committee meeting on Makena.

Objectives: To assess the utilization of HPC in pregnancy in the U.S.

Methods: We identified pregnant women aged 10-54 years, with a live birth from January 1, 2008 through April 30, 2018, and with continuous medical and drug insurance coverage for at least 301 days prior to a live birth delivery in the Sentinel Distributed Database (SDD). The exposures of interest included use of injectable HPC (Makena and its generics) and compounded HPC from bulk power during the 2nd or 3rd trimesters. We assessed three obstetrical conditions of interest as potential reasons for use: (1) history of preterm delivery, (2) preterm labor in the current pregnancy, and (3) cervical shortening in the current pregnancy. We evaluated the temporal trend of HPC use over the study period. Among pregnancies with injectable HPC use, we calculated the percentage of those with diagnoses for each related obstetrical condition; and the percentage of pregnancies with diagnoses for any of three related obstetrical conditions.

Results: We identified a total of 3,451,121 live-birth pregnancies (among 2,912,911 women) between 2008 and 2019 in the SDD. Of these pregnancies, 16,535 showed use of injectable HPC during the 2nd or 3rd trimesters. The yearly proportion of pregnancies with injectable HPC use increased over the study period from 0 in 2010 to 13 per 1,000 pregnancies in 2018; use of compounded HPC decreased from 4 to 0.25 per 1,000 pregnancies over the same time. Of 16,535 pregnancies with injectable HPC use, 6,443 (39%) had recorded history of preterm delivery and 12,060 (73%) had at least one related obstetrical condition.

Conclusions: We found modest use (about 1.3% in 2018) of HPC during the 2nd or 3rd trimesters of live-birth pregnancies in SDD. A high percentage (73%) of pregnancies with injectable HPC use had at least one obstetrical indication of interest.

2471 | The association between adherence to multiple chronic medications and healthcare utilisation in older community dwelling adults with multimorbidity

Caroline A. Walsh, Caitriona Cahir and Kathleen E. Bennett
Royal College of Surgeons in Ireland, Dublin, Ireland

Background: The evidence on measurement of adherence to multiple medications in older adults with multimorbidity is lacking.

Objectives: To (i) estimate medication adherence and identify patterns of suboptimal medication adherence in older people with multimorbidity and (ii) estimate the association between suboptimal adherence and healthcare utilisation.

Methods: This is a prospective cohort study using linked data from a national pharmacy claims database and Waves 1 and 2 of The Irish LongituDinal study on Ageing (TILDA). Morbidity was measured by the Rx-RiskV algorithm which classifies drug claims (ATC codes) into chronic disease classes. Participants with multi-morbidity and aged ≥70 years at wave 1 were identified by ≥2 RxRiskV conditions in the 6 months prior to wave 1 (baseline). Participants were included if they had ≥2 dispensings of the baseline RxRiskV medications in the 12 months after wave 1. Average adherence across RxRiskV conditions was estimated using continuous multiple-interval measure of medication availability (CMA7 function in AdhereR) over 12 months. Group-based trajectory models (GBTM) were used to group participants' adherence patterns. Negative binomial regression was used to estimate the association between adherence (average adherence and groups) and the number of self-reported primary care physician (GP) visits, Emergency department (ED) visits, outpatient visits and hospitalisations in the 12 months preceding wave 2. Adjusted IRR (aIRR) and 95% CIs are presented.

Results: In total 1050 participants were included. Average adherence among the population was 71% (SD 16%). GBTM identified 6 distinct adherence groups; (1) rapid decline, modest increase, (2) small decline, steep increase, (3) initial high adherence, rapid decline, (4) initial high adherence, delayed decline, (5) stable high adherence and (6) initial low adherence, rapid discontinuation. Higher average adherence was associated with a significant decrease in the number of GP visits (aIRR 0.70, CI 0.53, 0.94) and outpatient visits (aIRR 0.44, CI 0.23, 0.81). In comparison to group 5, group 1 membership (aIRR 1.72, CI 1.09, 2.73) and group 4 membership (aIRR 1.92, CI 1.19, 3.05) significantly increased the number of ED visits. Membership of group 6 significantly increased the number of outpatient visits in comparison to group 5 (aIRR 1.51, CI 1.08, 2.12).

Conclusions: Suboptimal medication adherence in older adults with multimorbidity increases healthcare utilisation. Interventions should target those with poor adherence patterns.

2490 | Comparison of a new three-item self-reported measure of adherence to medication with pharmacy claims data

Julie C. Lauffenburger[1], Constance P. Fontanet[1], Thomas Isaac[2], Chandrasekar Gopalakrishnan[1], Thomas D. Sequist[1], Joshua J. Gagne[1], Cynthia A. Jackevicius[3], Michael A. Fischer[1], Daniel H. Solomon[1] and Niteesh K. Choudhry[1]
[1]*Brigham and Women's Hospital, Harvard Medical School, Boston, MA;* [2]*Atrius Health, Newton, MA;* [3]*Western University of Health Sciences, Pomona, CA*

Background: Less than half of patients with cardiometabolic disease consistently take prescribed medications. While health insurers and some delivery organizations use insurer claims to measure adherence, most do not have rapid access to these data during routine interactions given administrative lag. Self-reported scales exist, but their practical utility is often limited by costs or length. By contrast, the accuracy of a new, free 3-item self-reported measure has been demonstrated in individuals with HIV but to our knowledge has not yet been compared with insurer claims or evaluated in other conditions.

Objectives: To evaluate the concordance between this self-reported tool and claims-based adherence measures in patients with cardiometabolic disease.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We used a linked pharmacy claims and electronic health record (EHR) dataset from a recently-completed pragmatic trial of patients with cardiometabolic conditions. After 12 months of follow-up, intervention subjects were mailed a survey with the 3-item measure that queries about medication use in the prior 30 days. As in prior research, responses were linearly transformed and averaged. Adherence was also measured in pharmacy claims in Month 12 and Months 1-12 of the trial using proportion of days covered (PDC) metrics. We compared sensitivity, specificity, and likelihood ratios (LR) for non-adherence between self-report (average<0.80) and claims (PDC<0.80) as the referent and varied the survey cutpoint for "non-adherence" as a sensitivity analysis.

Results: Of 459 patients returning the survey (response rate: 43.5%), 50% were non- adherent in claims in Month 12, while 21% were non-adherent based on the survey. Compared with claims, the specificity of the 3-item metric was high (Month 12: 0.93), and sensitivity was relatively poor (Month 12: 0.25). Positive and negative LRs were 1.46 (95%CI: 1.01-2.09) and 0.91 (95%CI: 0.82-1.00), respectively. Survey measures were similarly accurate for longer (12 month) claims measurement windows (e.g., Sensitivity: 0.24 and Specificity: 0.87 in Months 1-12). Varying the cutpoint for non-adherence to <0.90 and <1.0 for the survey improved accuracy.

Conclusions: A new 3-item self-reported adherence measure has high specificity but poor sensitivity for non-adherence compared to pharmacy claims in cardiometabolic disease. This tool may be useful for clinicians or healthcare organizations to identify those needing adherence support in the absence of rapid access to claims data, as any admission of non-perfect adherence could potentially prove actionable.

2517 | Almost half of seniors initiating oral bisphosphonate therapy are exposed for 3 or more years - Understanding the benefits and harms of prolonged therapy is needed

Kaleen N. Hayes[1], Kevin Brown[1], Angela Cheung[1], David Juurlink[1], Nancy He[2] and Suzanne M. Cadarette[2]

[1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada

Background: Oral bisphosphonates (BP, alendronate and risedronate) are the primary drugs used to treat osteoporosis in Canada. Clinical guidelines recommend at least 3 years of BP therapy to reduce fracture risk. The benefits and harms of continued therapy is uncertain. Rare but serious adverse events are associated with BP use >5 years.

Objectives: To describe patterns of long-term (≥3 years) BP use.

Methods: The Ontario government covers prescription drugs listed on the public formulary for residents aged ≥65 years. This includes alendronate and risedronate since 2000/11 for women and 2003/07 for men. We identified first dispensation of BP drugs among adults aged ≥66 years from 2000/11 to 2016/12, and followed them forward until death or 2019/12 to identify patients with ≥3 years of BP use (proportion of days covered ≥80%, using 3-year rolling window approach after each BP dispensation). Patterns of long-term BP use were described based on length of time between first BP dispensation and the start of long-term therapy period, and compared between men and women.

Results: We identified 260,784 eligible seniors initiating BP therapy in Ontario, mean age=75.4 (SD 7.1) years, 77% women, 57% risedronate. Of these, 47% (n=121,786) met criteria for long-term therapy, mean age=75.0 (SD 6.7) years, 79% women, 55% risedronate. The mean length of BP therapy was 7.6 (SD 3.4, median 6.9, 99th percentile 16.6) years for women and 6.7 (SD 3.0, median 6.0, 99th percentile 15.1) years for men. Overall, 31% of patients (33% of women, 26% of men) were treated for ≥5 years. Eighty percent met criteria for long-term therapy after their first BP dispensation, 6% had a gap <12 months, and 14% had a gap of ≥12 months. Eleven percent of long-term therapy patients switched between alendronate and risedronate, and 35% switched between brand and generic formulations. The annual number of patients undergoing long-term BP therapy increased steadily from 2001 (n=3,079) until peaking in 2007 (n=15,649), then decreased annually thereafter, reaching n=5,783 in 2016.

Conclusions: Almost half of patients initiating oral BP are exposed to long-term therapy, with 80% meeting a minimum 3 years of therapy after their first BP dispensation and 31% continuing therapy for at least 5 years. The benefits and harms of continuing BP therapy beyond 3 years are needed to inform the true effects of long-term exposure. Better understanding of switching between alendronate and risedronate and brand and generic formulations will inform studies that consider the relative effects of prolonged BP therapy.

2520 | Anti-hypertensive drug prescribing pattern, adherence to guidelines and blood pressure control at a teaching hospital in Ghana

Mark A. Harrison[1], Kwame O. Buabeng[2], Afia FA Marfo[2], Florence A. Nkansah[3], Franklin Acheampong[3], Godwin Gulbi[1], Daniel K. Arhinful[4] and Daniel NA Ankrah[3]

[1]Korle Bu Teaching Hospital, Accra, Ghana; [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [3]Korle Bu Teaching Hospital, Accra, Ghana; [4]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Background: Blood pressure (BP) control is low in many low and middle income countries, despite various therapy options. Current guidelines can help achieve outcomes improvement. Therefore, guideline adherence needs to be studied.

Objectives: To evaluate the pattern of anti-hypertensive (anti-HPT) drug prescribing, its adherence to hypertension treatment guidelines by clinicians at the Korle Bu teaching hospital (KBTH) and association with blood pressure control.

Methods: Over a 3-month period, we carried out a cross-sectional study of hypertensive out-patients attending the KBTH polyclinic for treatment. After patients were selected, their medical notes were reviewed to collect data on: patient demographics and BP; the pattern

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of anti-hypertensive drug class and combination prescribing; level of generic and single pill combination (SPC) prescribing. Adherence to guidelines was measured as prescribing pattern conformity to recommendations by the 2018 European Society of cardiology (ESC) and the 2017 Ghana Standard Treatment Guidelines (STG).

Results: Out of 310 questionnaires 304 were completed, and 31.6% were diabetic. Monotherapy and dual therapy were 18.8% (n=57) and 52.6% (n=160) respectively. The 5 leading drugs, calcium channel blockers (CCB), diuretics, angiotensin receptor blockers (ARB), angiotensin-converting enzyme inhibitors (ACE-I), and beta blockers were given to 86.8% (n=264), 45.7% (n=139), 33.2% (n=101), 27% (n=82), and 11.8% (n=36) of patients respectively. Majority (71.4%; n=217) were on amlodipine. For 2 drugs, 50% (n=80) were CCB plus a renin-angiotensin system (RAS) blocker. The most common were CCB plus diuretic (37.1%), CCB plus ACE-I (23.8%) and CCB plus ARB (26.2%). SPC and generic prescriptions were 2.8% (n=7) and 84.5% (n=256) respectively. BP control was 41.8%. The 5 leading drugs agreed with 1st line recommendations of the 2017 Ghana STG. The 5 leading drugs and pattern of combination therapy agreed with 2018 guidelines of the ESC. The number of anti-HPT drugs was negatively associated with BP control with significance. (B= -0.402; p-value=0.015). Amlodipine, indapamide and hydrochlorothiazide were more likely to result in BP control (OR=1.53, 95% CI: 0.91 - 2.58; OR=1.7, 95% CI: 1.54 - 1.89; OR=1.7, 95% CI: 1.55 - 1.87).

Conclusions: Anti-hypertensive drug prescribing was based on the 5 major drug classes, and the majority of patients received 2 drugs (CCB and RAS blockers). Prescribing pattern agreed with the Ghana and ESC guidelines but SPC prescribing needs to be improved. CCB and diuretics are more likely to control BP in Ghanaians.

2532 | Impact of delays in initiation of adjuvant endocrine therapy on survival among patients with breast cancer

Kimberley Lee[1], Jodi Segal[2] and Lisa Jacobs[3]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [3]*Johns Hopkins School of Medicine, Baltimore, MD*

Background: Time to adjuvant endocrine therapy concerns patients and clinicians, but its impact on overall survival is not clear. There are no population level studies that address this question.

Objectives: To describe the relationship between time from diagnosis of breast cancer to start of adjuvant endocrine therapy (AET) and overall survival.

Methods: This is a population-based cohort study using population level data from the National Cancer Database (NCDB). The NCDB prospectively collects data on incident cancer cases from over 1500 Commission on Cancer-accredited facilities in the United States. The participants are women with Stage II and III estrogen or progesterone receptor positive (HR+), human epidermal receptor 2 negative, invasive breast cancer who underwent definitive surgical treatment. Multivariable Cox proportional hazards regression analyses were used to assess the impact of time to endocrine therapy on overall survival, after adjusting for patient, demographic, tumor-, and treatment-related factors.

Results: Of the 391,594 women in this study, 12,162 (3.1%) began treatment with adjuvant endocrine therapy more than 12 months after initial diagnosis of HR+ invasive breast cancer. Mean age at diagnosis was 59.7 years (SD 13.4). Predictors of delayed initiation of AET include Black race or Hispanic ethnicity (adjusted odds ratio [aOR] of Black vs White, 1.57; 95% CI, 1.48-1.66; P<.001, Hispanic vs White, aOR 1.22, 95% CI 1.13-1.32; P<.001), Insurance other than private insurance (Medicare vs Private, aOR 1.09, 95% CI 1.01-1.17; P=.007, Medicaid vs Private, aOR 1.36, 95% CI 1.28-1.45; P<.001), higher stage of disease at diagnosis (Stage III vs II, aOR 1.24, 95% CI 1.19-1.30; P<.001), and delayed surgery or chemotherapy (Delayed surgery vs On-time lumpectomy, aOR 2.76, 95% CI 2.60-2.93; P<.001 and Delayed chemotherapy vs no chemotherapy, aOR 11.5, 95%CI 10.6-12.5). With median follow-up of 63.2 months, 67,335 (17.2%) patients died by the end of follow-up. Delayed initiation of AET resulted in no change in the hazard of death (HR, 1.00; 95% CI, 0.95-1.05; P=.97) compared to initiation within 12 months of diagnosis after adjusting for age, race and ethnicity, insurance type, urban vs rural residence, neighborhood income and education, comorbidity, cancer grade, stage, and receipt of timely or delayed surgery, chemotherapy, and/or radiation therapy.

Conclusions: These results suggest that there may be no detriment to survival if initiation of adjuvant endocrine therapy occurs 12 to 24 months after initial diagnosis compared to within 12 months of diagnosis as currently recommended.

2543 | Community pharmacy practice evaluation in the United Arab Emirates using simulated patients with common cold

Subish Palaian[1], Muaed Al Omar[1], Nageeb Hassan[1], Dina Mourad[2], Waad Ahmed[2] and Arig Ewida[2]

[1]*College of Pharmacy and Health Sciences, Ajman University, Ajman, United Arab Emirates;* [2]*College of Pharmacy and Health Sciences, Ajman University, Ajman, United Arab Emirates*

Background: Patients seek medical advice from pharmacists regarding minor ailments. Pharmacists on the other hand are expected to counsel patients appropriately and dispense medications rationally. Simulated client method using 'Mystery patients' provides opportunity to investigate and explore actual dispensing practices (including client-provider interactions).

Objectives: To explore the dispensing and counseling practices of community pharmacists in United Arab Emirates.

Methods: A simulated client study was conducted among a conveniently selected 34 community pharmacies in Ajman, UAE in January 2020. Three simulated clients (third year pharmacy students) visited community pharmacies and exhibited symptoms of common cold (ICD-10 code J00). Uniformity was maintained while exhibiting symptoms across pharmacies and each of them exchanged their roles

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

routinely across encounters. Ethical approval was obtained for the research and pilot tested with three pharmacies. Filled checklists were analyzed and statistical analysis performed using Pearson correlation coefficient and independent t-test at α =0.05.

Results: The Simulated clients' interaction was with 9 female and 25 male pharmacists, five Arabs versus 29 non-Arabs. All pharmacists dispensed at least one medicine (average 3.08; n=105). Most common therapeutic category was antihistamines (21.90%; n= 23), followed by expectorants (16.19%; n=17). Commonly dispensed medicines were pseudoephedrine+Loratidine combination (n=8; 7.61%), followed by guaifenesin+pseudoephedrine+dextromethorphan+paracetamol in 6 (5.71%) cases. Only 12 pharmacists counseled on 'treatment duration' and none asked about 'medical history'. The labeling 'when to take' was mentioned by 20 (58.82%) pharmacists with the average dispensing time of 37.20± 25.97 seconds. Dosage regimen was appropriately chosen in 22 (64.70%) pharmacies. The average cost of medicines per patient was AED 55.32±36.93 (1 USD= 3.67 AED). Only one pharmacist counseled on medication allergy, 4(11.76%) on side effects, 2(5.88%) on contraindications, 3(8.82%) on drug-drug interactions and 31(91.17%) pharmacists provided appropriate instructions on medications usage. The average counseling time was 75.29 ± 74.62 seconds. Counseling duration had a positive correlation with cost (p=0.015), dispensing duration (p=0.000) and associated with race (p=0.003) but not gender (p= 0.8).

Conclusions: Pharmacists spent less time in understanding patients' condition and counseling. They were predominantly selling medicines with little or no information on safe and effective usage.

2585 | Longitudinal cumulative dose: A novel measure to evaluate multiple dimensions of chemotherapy adherence over time

Michael A. Webster-Clark[1], Alexander Keil[1], Hanna K. Sanoff[2], Til Stürmer[1], Daniel Westreich[1] and Jennifer L. Lund[1]

[1]*University of North Carolina, Chapel Hill, NC;* [2]*University of North Carolina, Chapel Hill, NC*

Background: Adjuvant chemotherapy regimens take months to complete, as do many other pharmacologic treatments. Despite this, clinical trials and observational studies often evaluate chemotherapy adherence via measures assessed at the end of treatment or end of an arbitrary time period (e.g. proportion of patients missing any dose, relative dose intensity [RDI], proportion of days covered). This approach may miss information patients and providers value that impacts outcomes, like timing of treatment delays.

Objectives: We sought to explore longitudinal cumulative dose (LCD) as a way to integrate the impact of dose reductions, missed doses, and dose delays at each visit on treatment received over time.

Methods: We obtained data from the 2,246 participants in the Multicenter International Study of Oxaliplatin/5FU-LV in the Adjuvant Treatment of Colon Cancer (MOSAIC). We evaluated proportions of patients stopping treatment early, reducing a dose (based on the trial's protocol), missing a dose, or delaying a dose in each treatment arm for each chemotherapeutic agent at each visit. We obtained LCD, the fraction of the final standard dose a participant reached by a given day, for each participant and each chemotherapeutic agent. We compared LCD medians and interquartile ranges over time and at the end of the standard regimen (24 weeks) between and within treatment arms with respect to age and performance status. We also assessed agreement between LCD and RDI with Fleiss' kappa.

Results: Participants randomized to FOLFOX were more likely than those randomized to 5FU to stop treatment, reduce doses, miss doses, or delay visits; these differences increased over time. Median LCD for oxaliplatin in the FOLFOX arm at 24 weeks was 77%. Graphs of median LCD for 5FU showed a clear difference between arms (FOLFOX arm median LCD: 81%; 5FU arm median LCD, 96%). While 5FU LCD decreased with age in the FOLFOX arm (median LCD in those age <40: 85%; 40-64, 82%; 65-75, 76%), it was similar across ages in the 5FU arm (median LCD of 94%, 96%, and 96%, respectively), with smaller trends for performance status. There was only fair agreement between RDI and LCD (Fleiss' kappa of 0.34); 19% of those with RDI over 85% had LCD under 60%.

Conclusions: Visualizing the LCD highlighted the timing and scale of deviations from standard courses of therapy and illustrated major differences in 5FU treatment across arms. Next steps include evaluating how well LCD predicts clinical outcomes as an integrated measure of adherence as well as exploring deviation from the ideal LCD as a way to measure adherence to other types of interventions.

2603 | Antihypertensive polytherapy in Australia: Prevalence of inappropriate combinations, 2013-2018

Michael O. Falster[1], Nicholas A. Buckley[2], David Brieger[3] and Sallie-Anne Pearson[1]

[1]*University of New South Wales, Sydney, Australia;* [2]*University of Sydney, Sydney, Australia*[3]*Concord Hospital, Sydney, Australia*

Background: Antihypertensive polytherapy plays a significant role in treating hypertension and is endorsed increasingly in hypertension guidelines. There has been little population-based research to better understand how antihypertensive combinations, particularly inappropriate polytherapy, are used in routine clinical care.

Objectives: To estimate the prevalence of inappropriate antihypertensive polytherapy in Australia.

Methods: We conducted a retrospective cohort study using pharmaceutical claims data. We used a nationally representative 10% sample of Pharmaceutical Benefits Scheme (PBS) eligible Australians and their dispensing history to identify people aged 18+ years exposed to at least one PBS-listed antihypertensive, 2013-2018. We measured annual: prevalence of antihypertensive polypharmacy (≥40 days concomitant exposure), inappropriate antihypertensive combinations (against guideline recommendations; within-class polytherapy) and combinations to be used with caution.

Results: Almost half (47.5%) of people using antihypertensives in 2018 experienced polytherapy. Among these, 2.4% had an

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

inappropriate combination (1.5% against guidelines; 1.0% within-class polytherapy). Inappropriate combinations were more prevalent in people experiencing polytherapy with three (3.7%) or four (16.1%) antihypertensive medicines than people on dual therapy (0.7%). Inappropriate combinations occurred at a lower rate in people using fixed-dose rather than free-drug combinations for dual therapy (0% vs 0.7%; p<0.01) and in those using three antihypertensives (2.4% vs 7.3%; p<0.01); this was not the case for people using four or more antihypertensives (15.5% vs 16.1%; p=0.39). Between 2013-2018 the prevalence of antihypertensive polytherapy was relatively stable (49%-47%), however the prevalence of inappropriate combinations among these patients halved (from 5.1%-2.4%).

Conclusions: Antihypertensive polytherapy in Australia is common, but the prevalence of inappropriate combinations is low and is decreasing, suggesting strong awareness of Australian clinical guidelines. However, in 2018 approximately 49,000 Australian adults experience inappropriate polytherapy; prescribing of fixed-dose combinations in patients on dual or triple therapy may further reduce this inappropriate care, although increased vigilance treating patients with >3 antihypertensives is required.

2604 | Long-term trajectories of medicine use among older adults experiencing polypharmacy in Australia

Michael O Falster[1], Rayan Charrier[1,2], Sallie-Anne Pearson[1], Nicholas Buckley[3] and Benjamin Daniels[1]

[1]University of New South Wales, Sydney, Australia; [2]École Polytechnique, Paris, France[3]University of Sydney, Sydney, Australia

Background: Polypharmacy (the concurrent use of five or more medicines) is often considered a marker of potentially inappropriate care. Patients experiencing polypharmacy may follow a diverse range of clinical pathways, yet there is little understanding about how the number and nature of medicine use changes over time.

Objectives: To identify common pathways of medicine use over time among older patients experiencing polypharmacy.

Methods: We conducted a retrospective cohort study using administrative pharmaceutical claims data for a 10% sample of Australian Pharmaceutical Benefits Scheme (PBS) beneficiaries. We identified people aged 70 years and over who were exposed to five or more medicines on February 15, 2014. Using group-based trajectory modelling, we explored changes in the quarterly number and type of medicines people used over a five-year period (2014-2018).

Results: In our cohort of 98,539 older people, we identified two groups of people experiencing polypharmacy encompassing seven distinct trajectories: sustained polypharmacy (77% of people, 4 trajectories); and decreasing medicine use (23%, 3 trajectories). Patients in sustained polypharmacy trajectory groups with a lower mean number of medicines (e.g. 6 unique medicines) had relatively stable trajectories, while those with a higher mean number of medicines (e.g. 15 unique medicines) experienced greater seasonal variation in both the number and type of medicines used. Within the sustained polypharmacy trajectories, patients retained on average two-thirds of their medicines of exposure (chemical substance level) between adjacent quarters. For patients in decreasing medicine use trajectories, the most common trajectory was a slight drop in medicine exposure within the first three months. Overall, 21% of patients were no longer experiencing polypharmacy after one year.

Conclusions: Polypharmacy among older patients is largely a chronic phenomenon, reflecting the nature of multimorbidity within this population. However, there is an underlying volatility in the medicines involved, reflecting both changes in treatment and seasonal fluctuation in medicine dispensing. Care must be taken when measuring and interpreting polypharmacy, as a single measure may not reflect a patients' sustained medicine use over time.

3740 | Quality of buprenorphine care for opioid use disorder

Kelly E. Anderson[1], Julia Eckstein[1], Christine E. Chaisson[2], Sarah H. Scholle[3], Lauren Niles[1,3], Sydney M. Dy[1], Brendan Saloner[1] and G. Caleb Alexander[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]OptumLabs, Cambridge, MA; [3]National Committee for Quality Assurance, Washington, DC

Background: Buprenorphine has unique advantages to treat opioid use disorder (OUD) that facilitate its use in ambulatory settings. Buprenorphine does not require complete opioid abstinence before initiation, and is not restricted to specialized treatment programs; however, clinicians must undergo training and receive a waiver to prescribe it. High-quality, effective buprenorphine treatment includes continuous medication use and the absence of prescription fills for other opioids.

Objectives: To characterize quality of buprenorphine care for OUD by quantifying buprenorphine initiation, engagement, and maintenance for individuals in a large, diverse, real-world cohort in the United States.

Methods: Retrospective cohort analysis of 33,617 commercial and Medicare Advantage enrollees aged ≥18 years in the OptumLabs® Data Warehouse diagnosed with incident OUD between 1/1/16 and 12/31/17, with insurance coverage gaps ≤45 days in the year before and after diagnosis. We calculated 5 measures of buprenorphine treatment quality for individuals with OUD. We analyzed the association of clinical and sociodemographic characteristics with quality of buprenorphine treatment using ordered logistic regressions. Finally, we conducted a survival analysis to examine patterns in treatment duration.

Results: Of the 33,617 individuals included in the study, 1,962 individuals (5.8%) received buprenorphine at least once in the 365 days following diagnosis (Measure 1 - Any Buprenorphine), and 1,421 individuals (4.2%) received buprenorphine within 14 days of diagnosis (Measure 2 - Initiation). Of the 1,421 individuals who initiated buprenorphine, 812 (57.1%) had ≥2 claims for buprenorphine within

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

34 days of initiation (Measure 3 - Engagement). Only 1,161 individuals (3.5%) had 180 days or more of covered buprenorphine treatment in the 365 days following diagnosis (Measure 4 - Maintenance). Of the 1,962 individuals eligible, 730 (37.2%) filled an opioid prescription within the 180 days after receiving buprenorphine (Measure 5 - Concurrent Opioid Prescription). Compared to individuals who were white, individuals who were black had a 33.8% reduction in the odds of receiving higher quality buprenorphine treatment (OR = 0.66, 95% CI: 0.55-0.80) and individuals who were Hispanic had a 24.6% reduction in the odds of receiving higher quality buprenorphine treatment (OR = 0.75, 95% CI: 0.62-0.91).

Conclusions: While buprenorphine can reduce mortality for individuals with OUD, we found widespread and enduring gaps in its use that extended beyond treatment initiation, and that reflect disparities in quality of care based on the sociodemographic characteristics examined.

3763 | Patterns of direct-acting antivirals (DAAs) use for hepatitis c: A population-based cohort study in France

Anne Bénard-Laribière[1], Elodie Pambrun[1], Elisabeth Polard[2], Pernelle Noize[1] and Antoine Pariente[1]

[1]*Univ. Bordeaux, Inserm, Bordeaux Population Health Research Center, Team PHARMACOEPIDEMIOLOGY, UMR 1219, Bordeaux, France;* [2]*Pharmacovigilance, Pharmacoepidemiology and Drug Information Centre, Department of Clinical Pharmacology, Rennes University Hospital, Rennes, France*

Background: DAAs have revolutionized the prospect of ending HCV epidemic over the coming years; but these were launched at very high prices in 2013, leading to a prioritization strategy for access to treatment based on fibrosis stage or high risk of transmission until May 2016 in France.

Objectives: To identify situations minimizing the likelihood of benefits for patients who initiated DAA treatment.

Methods: A population-based cohort study was performed using data from the French reimbursement healthcare system. New DAA users, who started treatment between September 2013 and June 2017, were followed until December 2017, date of death, or end of data availability. DAA exposure was estimated by using dates of successive DAA reimbursements, each reimbursement allowing 28 days of treatment. Discontinuation of DAA treatment episode was considered if no reimbursement was issued within 42 days after the last reimbursement. This study assessed patient characteristics, treatment duration, adherence to DDAs, retreatment of patients who failed after their first DAA regimen.

Results: The 2013-2017 cohort of new DAA users comprised 43,474 individuals. Median age was 55 years (IQR 50-64y); most were male (59.3%). Changes in patient characteristics were noticed after the announcement of the universal access to DAAs in 2016: women were prescribed DAAs more frequently, and access to DAAs for younger HCV infected patients with a non-advanced disease stage was enlarged. Nearly 92% of new DDA users (n=39,840) had a single treatment episode, during which 97% of drug regimens complied with the recommendations. Non-compliant regimens mostly consisted of monotherapy of DAAs that are indicated in combination with other DAAs or ribavirin (RIB), especially sofosbuvir (SOF). Single reimbursement of DAA was uncommon (5 to 9% of users according to the DAA). More than 75% of users of elbasvir/grazoprevir, ledipasvir/SOF, velpatasvir/SOF, and ombitasvir/paritaprevir/ritonavir (OPr) + dasabuvir had duration of use that complied with recommendations; it was between 60 and 70% for users of simeprevir/SOF, daclatasvir/SOF, and OPr + RIB. One third of users of SOF + RIB had adequate duration of use. Nearly 5% of new DAA users were considered as non-adherent. Retreatment of patients who failed after DAA regimen was estimated to be nearly 3%.

Conclusions: Results, obtained at a nationwide level, suggested optimal patterns of DAA use, allowing to expect benefits for patients: DDA use mostly complied with recommendations of treatment combination and duration of use, with low rates of non-adherence and of retreatment after DAA regimen failure.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 3803 | Assessment of drug utilisation evaluation of anti-retroviral therapy and medication adherence behaviour of patients receiving medication at a district hospital in South India

Adepu Ramesh, Sonali Bendeskar, Akhila Gandikota and Divya Ramulakollu
Vikas College of Pharmaceutical Sciences, Suryapeta, Nalgonda, India

Background: Use of HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART) has substantially reduced the death rate and made AIDS as manageable. a minimum of 95% adherence to medication is essential to keep the viral load under control. In India, National AIDS Control Organisation guidelines are followed to treat HIV patients. Thus it is essential to assess the prescription pattern of ART and its outcomes.
Objectives: To assess the drug utilization pattern of ART in HIV patients visiting a local ART center and also to study the medication adherence behavior among the study patients.
Methods: A prospective observational study was carried out. Details of demographic, clinical, laboratory and the treatment initiated were collected on a daily basis for new cases and the add on data was collected for old cases. Using standard National AIDS Control Organisations guidelines, staging and treatment pattern was assessed. Morisky Medication Adherence Scale-8 was applied for assessing the medication adherence behavior.
Results: During the study period, a total of 505 HIV patients were enrolled and analyzed. Among them, the majority of patients were women (61%), between the age group of 31-45(49.7%) and illiterate (52.6%). The major mode of transmission was intimate contact (74%) and the majority were in Stage I (49%). TLE regimen was prescribed in 69.9% of patients and for children, the prescribed regimen was ABC,3TC, EFV (5.1%). Nearly 220(43%) patients were found with medium adherence.
Conclusions: This study concludes that the most prescribed regimens constituted a combination of TLE [Tenofovir + Lamivudine + Efavirenz] and the majority of patients were found with medium adherence.

3849 | Medication errors: A perspective from four hospitals in rural Kenya

Perpetua Karanja
Kirinyaga County, Kerugoya, Kenya

Background: Medication errors contribute to patient morbidity and mortality and are a major concern in patient safety. Medication errors are common, preventable and can occur at any stage of medication use such as prescribing, dispensing and administration. Medication error reporting is important to ensure medication safety and identify areas of improvement in practice.
Objectives: To describe medication errors reported routinely in four rural hospitals in Kenya.
Methods: This was a descriptive study of medication error reports received from four hospitals in rural Kenya in 2019. Data were extracted using a standardized medication error reporting form from prescriptions presented at the pharmacy departments of the four hospitals. The study population was patients visiting the hospitals who received prescriptions for their treatment. The data was then coded and entered into REDCap™ and analyzed using STATA 13.
Results: There were 54 reported medication errors, with about 70% being captured in the outpatient department. The errors were more common among female patients and amongst adults (18-59 years olds). More than half (52%) were reported in the largest of the four facilities. Out of these, 78% occurred at the prescribing stage and 19% at the dispensing stage. 85% of the medication errors were recognized and corrected before reaching the patient and 7% of these had a capacity to cause an error due to look-alike packaging. Only 4 % of the errors that reached the patient caused temporary harm while 9% caused no harm and 2% was unknown. Antibacterials were the most affected class of drugs at 39 % followed by antihypertensives at 11%. The wrong drug was the most common type of error at 33% followed closely by improper doses at 25%. Continuous medical education was the most recommended action at 81%; others were distinct packaging of medicines and direct supervision of trainees.
Conclusions: Prescribing errors are the most prevalent errors mainly affecting antibacterial agents hence the need for antimicrobial stewardship. Pharmaceutical personnel play a great role in identifying and preventing medication errors. Medical education should be done continuously to keep health care workers abreast of updates in health practice.

3878 | The opioid epidemic in the Netherlands, causes and consequences

Ajda Bedene[1,2], Eveline L.A. van Dorp[2], Tariq Faquih[1], Suzanna C. Cannegieter[1,3], Dennis O. Mook-Kanamori[1,4], Marieke Niesters[2], Monique van Velzen[2], Maaike G.J. Gademan[1,5], Frits R. Rosendaal[1], Marcel L. Bouvy[6], Albert Dahan[2] and Willem M. Lijfering[1]
[1]Leiden University Medical Center, Leiden, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Leiden University Medical Center, Leiden, Netherlands; [5]Leiden University Medical Center, Leiden, Netherlands; [6]Utrecht Institute for Pharmaceutical Sciences, University Utrecht, Utrecht, Netherlands

Background: Opioid use has risen in the Netherlands.
Objectives: To determine potential causes and consequences of the increased opioid prescription in the Netherlands.
Methods: Design: Cohort study.
Setting: Dutch national statistics from 2013 to 2017 and annual national Health Surveys from 2014 to 2017. We included the total Dutch population, e.g., 17,081,507 residents in 2017 and around 38,000 respondents of the national Health Surveys.
Exposures or interventions: opioids, nonsteroidal anti-inflammatory drugs (NSAIDs)
Main outcome measure: analgesics prescriptions, opioids and NSAIDs, hospitalizations and deaths due to opioid poisoning, and severity and prevalence of pain.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Statistical analysis: We conducted descriptive statistics into national prescription, hospitalization and mortality registry. We presented findings as proportions of the total population per calendar year, and as risk ratios (aRR) with 95% confidence intervals (CI), adjusted for age and sex with direct standardization, comparing annual incidence with the incidence of the reference year, i.e., 2013. Similar analyses were performed in the 2014-2017 Health Surveys where we selected 2014 as a reference year.

Results: From 2013 to 2017 the proportion of Dutch residents receiving opioid prescription rose from 4.9% to 6.0%. During this period, the use of NSAIDs decreased (15.5% and 13.7% of Dutch residents in 2013 and 2017, respectively), while the total number of individuals receiving prescriptions for any analgesic was largely unchanged (n=2,998,925 in 2013 and n=2,887,389 in 2017). Self-reported pain prevalence and severity remained constant over the observation period (44.7% of 5119 reported no pain-impeded activities of daily living in 2014, aRR, 1.00; [95% CI, 0.95-1.06] in 2017 vs 2014).

Simultaneously, we observed an increase in hospitalization and death due to opioid poisoning related to opioid prescription (3.4 and 6.6 per 100,000 inhabitants in 2013 and 2017, respectively) and to either in-hospital or illicit opioid use (5.2 and 6.3 per 100,000 inhabitants in 2013 and 2017, respectively). Of those hospitalized for opioid poisoning 3.9% of 1,343 died in 2013 and 4.6% of 2,055 in 2017. Duration of opioid poisoning hospitalization was prolonged over the observation time, as 15.3% of 1,343 patients were subsequently transferred to another health facility in 2013 and 21.3% of 2,055 in 2017.

Conclusions: We demonstrated that NSAIDs prescription decreased and opioid prescription increased in the Netherlands since 2013, without an increase in prevalence and severity of pain. Incidence of severe outcomes related to opioids increased over the observation period.

3936 | Prescribed daily doses of anti-dementia drugs in South Africa: A database analysis

Ilse Truter

Nelson Mandela University, Port Elizabeth, South Africa

Background: Few drug utilisation studies have been published in South Africa on anti-dementia medication management, despite a growing population of people with dementia. Memantine (an N-methyl-D-aspartate (NMDA)-receptor antagonist) and the anticholinesterases (donepezil, galantamine and rivastigmine) are used for symptomatic treatment. There is especially a paucity of information on the dosages in which these medications are prescribed.

Objectives: The primary aim of the study was to analyse the prescribing patterns of anti-dementia drugs, focussing on the Prescribed Daily Doses (PDDs).

Methods: A retrospective drug utilisation study on a section of the private healthcare system in South Africa for 2018 was conducted. All products in Anatomical Therapeutic Chemical (ATC) subgroup N06D (anti-dementia drugs) were extracted and analysed. Only the products that were reimbursed by the different medical insurance schemes were included in the study. Descriptive statistics were calculated.

Results: A total of 42 patients received 211 products in ATC subgroup N06D during the year. The average age of the 42 patients was 67.00 (SD=19.14) years. Only memantine (N06DX01), donepezil (N06DA02) and ginkgo biloba (N06DX02, one prescription) were reimbursed. Memantine accounted for 56.40% of prescriptions. For both memantine and donepezil, the originator and four branded generics were prescribed. Eighty percent of prescriptions were dispensed by community pharmacies, and the rest in hospitals. The prescriptions dispensed in hospitals were for small quantities for short term use and were not included in the dosage analysis. The average PDD of memantine was 22.13 (SD=12.75) mg, which is slightly higher than the Defined Daily Dose (DDD) of 20 mg. Specific average PDDs were 10 mg, 20 mg and 40 mg (with one 60 mg). The average PDD for donepezil was 9.23 (SD=1.82) mg (range: 5 mg to 10 mg), which is also higher than the DDD of 7.5 mg. Only three patients received both memantine and donepezil during the year, confirming that combination therapy was not common.

Conclusions: Anti-dementia drugs constituted a small percentage of prescriptions in this private healthcare setting. For both memantine and donepezil, the average PDDs were higher than the DDDs and recommended maximum maintenance doses. This may be as a result of reports that higher dosages of these active ingredients may result in better therapeutic outcomes in selected patients. Further studies are recommended.

3941 | A descriptive study of the clinical experiences of healthcare providers with the use and quality of oxytocin injection across the six geo-political zones of Nigeria

Chioma S. Ejekam[1], Chimezie Anyakora[2], Florence Nyangara[2] and Jude Nwokike[2]

[1]Lagos University Teaching Hospital, Lagos, Surulere, Nigeria; [2]United States Pharmacoepia(USP), Rockville, MD

Background: Oxytocin is recommended as an affordable and effective drug in the prevention of postpartum hemorrhage (PPH)-one of the leading causes of maternal morbidity and mortality in low- and middle-income countries (LMICs), however there are concerns about its proper use and quality in LMICs.

Objectives: To assess the knowledge, practices and experiences of healthcare-providers around oxytocin injection in their clinical practices in Nigeria.

Methods: This was a descriptive cross-sectional study that surveyed 6,299 healthcare-providers who deliver babies, recruited from 1,894 health facilities in Public (52%), Private (47%) and Nonprofit (<1%) sectors that offer obstetrics and gynecological services across 12 states in the 6 geo-political zones of Nigeria. Data were collected using an electronic questionnaire, analyzed using SPSS, and presented in frequencies and percentages. Funding support was provided by MSD for Mothers USA.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Overall, about 46% of respondents (52.8% in private; 40.0% in public facilities) had proper knowledge on the correct storage of oxytocin at +2-8°C. Proper knowledge also varied by state with highest levels in Jigawa (84.9%) then Nasarawa (70%), professional cadre (doctors>nurses>CHWs) and by years of experience in practice (those with less than 10 years > those with more than 10 years), and by sector (private sector >public sector). Only 34% of the respondents (41%-private and 27.5%-public sector) reported that oxytocin is properly stored in the refrigerator at +2-8°C in their healthcare facility. About 77.9% of the respondents used oxytocin for prevention of PPH, 66.7% for augmentation of labor and 52.6% for induction of labor. Surprisingly, about 1/3rd of CHWs used oxytocin for augmentation (32.8%) and for induction (31.6%), indications that they are unauthorized in. High percentages of respondents who used oxytocin for prevention of PPH used above 10IU (WHO-recommended dose) for primiparous (43.1%) and multiparous (49%) women. Respondents perceived that most of the existing oxytocin brands were effective, while 21% reported experiencing oxytocin failure.

Conclusions: Poor knowledge of healthcare-providers on the proper storage of oxytocin may have contributed to poor storage practices. The widespread use of oxytocin above the WHO-recommended dose might be an indicator of healthcare-provider concerns about oxytocin's quality. Hence, clinical guidelines and trainings of healthcare-providers on the use of oxytocin for PPH prevention should be developed and applied to ensure oxytocin quality.

3954 | Anti-diabetic drug utilization knowledge and glycemic index control in patients with uncontrolled diabetes mellitus

Naima Ahmed Tamanna
Islamic University, Kushtia, Bangladesh

Background: Diabetes has become the seventh leading burden of diseases in South Asia. Roughly 1 in 13 achieves treatment targets to keep control of the glycaemic index, one of the reasons may be lack of diabetic drug utilization knowledge. However, there is not much research done on the impact of drug utilization knowledge to achieve glycaemic control in Bangladesh.

Objectives: We aimed to investigate the proper anti-diabetic drug use and glycemic control among uncontrolled diabetic patients.

Methods: A prospective intervention study carried out from September 2017 to August 2018 in BIRDEM General Hospital, Bangladesh. A structured diabetic education regarding the disease, medication adjustment (e.g. Metformin) and glucose monitoring including exercise management was provided to each patient separately and patients were followed in 3 months. Data were analyzed using a logistic regression through SPSS.

Results: Metformin was used for 47% patients and 59% of patients took Metformin plus Insulin. For the intervention group, the average HbA1c significantly ($p < 0.001$) changed from baseline (11.59±2.48) to end of the follow-up (7.55±0.58). Similarly, Systolic Blood Pressure and Diastolic Blood Pressure changed from (138.31±15.73) to (126.90±11.15) and from (83.33±6.50) to (80.24±4.12), respectively ($p < 0.001$). Higher educated patients were more likely to have improved on glycemic control than lower educated patients [OR=1.5, CI=0.24-9.30].

Conclusions: Proper knowledge on anti-diabetic drug utilization can help in glycemic control to include prevention of diabetes, improved quality of life and delaying of complications.

4046 | Titration: Where is the real-world evidence?

Aisling R Caffrey[1,2,3] and Eric P Borrelli[1]
[1]*College of Pharmacy, University of Rhode Island, Kingston, RI;* [2]*Providence Veterans Affairs Medical Center, Providence, RI;*[3]*School of Public Health, Brown University, Providence, RI*

Background: Drug titration is an individualized, patient-centered approach to dosing medications with a narrow therapeutic index in order to optimize therapeutic benefit while minimizing risk of adverse effects, and is commonly used with anticoagulants, anticonvulsants, antidepressants, antidiabetics, antipsychotics, opioids, stimulants, and certain antibiotics.

Objectives: To describe the complexities of drug titration and present examples which illustrate challenges in measuring titration schedules in clinical practice.

Methods: A literature review was conducted to identify various approaches to drug titration and challenges with drug titration, including real-world evidence supporting titration. Additionally, the de-identified Optum Clinformatics DataMart™ (2010-2015) and national Veterans Affairs (VA) data (2014-2018) were utilized to identify possible medication titration with anticonvulsants in clinical practice, based on days supply and quantity, or sig, respectively.

Results: Drug titration may occur as up-, down-, or cross-titration depending on whether the goal is to reach or maintain a therapeutic level, decrease the risk of adverse effects, and/or prevent withdrawal/discontinuation syndromes or recurrence of disease. In clinical practice, wide variations in titration schedules exist due to a lack of evidence and consensus on titration schedules that achieve an optimal benefit-harm profile. Further, drug titration is challenging for patients to follow and requires greater coordination of care amongst providers. Despite labelled titration schedules for initiation of anticonvulsants, which would represent near universal titration, possible titration was only observed in 4.3% of patients (n=93,601/2,179,601) in the Optum Clinformatics DataMart™ cohort. Possible titration was most common among patients receiving lamotrigine (9.1%), valproate (7.4%), topiramate (7.3%), and oxcarbazepine (6.4%). Even in the VA data (n=309,740), where sig was available, sigs indicating titration were uncommon, and when sig titrations were available, they varied widely, even for the same medication, and did not indicate labeled titration (i.e. oxcarbazepine up-titration every two days rather than weekly).

Conclusions: Current data systems do not accurately reflect medication titration in clinical practice. As a result, real-world evidence from comparative effectiveness and comparative safety research with

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

titrated medications is lacking. Therefore, data system improvements are needed in order to accurately capture medication titration, so that titration approaches and associated clinical outcomes can be studied.

4048 | Fracture rates in patients discontinuing alendronate treatment in real-life: A nationwide cohort study

Bianka Darvalics[1], Anne Sophie Sølling[2], Diana H. Christensen[1], Torben Harsløf[2], Reimar W. Thomsen[1] and Bente Langdahl[2]
[1]*Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark;* [2]*Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark*

Background: Based on the FLEX trial, it has become clinical practice to discontinue the bisphosphonate alendronate (ALN) after 5 years of treatment for osteoporosis. However, information on the fracture risk after ALN discontinuation in a real-life setting is sparse.
Objectives: To examine ALN discontinuation patterns and to compare fracture rates in patients discontinuing ALN after 5.0-5.5 years of treatment to fracture rates in patients continuing ALN treatment for more than 5.5 years.
Methods: We conducted a population-based cohort study using Danish health registry data. The source population was patients living in Denmark who had redeemed at least two ALN prescriptions between January 1st 1995 and September 1st 2017 (n=186,219). ALN discontinuation was defined as no prescription redemption within the days' supply of a prescription + a grace period of 8 weeks (stock piling method). Using an on-treatment approach, we followed patients with PDC ≥ 80% who either discontinued ALN after 5.0-5.5 years or continued ALN beyond 5.5 years from 5.5 years after their first ALN prescription until fracture, change of ALN exposure status, death, emigration, 5 years of follow-up or study end. We used Cox proportional hazard regression analyses to adjust for potential confounding factors associated with both ALN use and risk of fractures.
Results: We found that 25% of ALN initiators used ALN for less than one year and only 43% continued treatment for more than 5 years. The incidence rate of any fracture was similar in those who discontinued ALN (55.3 events per 1000 person-years) compared to those who continued ALN (55.4 events per 1000 person-years). ALN discontinuation after 5 to 5.5 years of treatment was not associated with an increased risk of vertebral fractures (hazard ratios (HR) 0.59, 95% CI 0.33-1.06), hip fractures (HR 1.04, 95% CI 0.75-1.45) or major osteoporotic fractures (HR 1.05, 95% CI 0.88-1.25), when compared with ALN continuation. These results were robust in an additional intention-to-treat analysis. We found similar results with varying grace periods, with 6 month delayed start of follow-up, and in age-, sex-, and calendar year-stratified analyses.
Conclusions: Less than half of all ALN initiators in Denmark continue treatment beyond 5 years. Discontinuation of ALN treatment after 5.0-5.5 years was not associated with a subsequently increased fracture risk within the first 5 years after discontinuation, when compared with patients who continued ALN for more than 5.5 years.

4049 | Inappropriate empiric treatment with antibiotics in a tertiary hospital, in Kenya

Zaietuni A. Mulaa[1], Maureen Nerima[2] and Hilda K. Daywa[2]
[1]*University of Nairobi, Nairobi, Kenya;* [2]*Trans-Nzoia County, Kitale, Kenya*

Background: Many studies have linked irrational and misuse of antibiotics with development of antibiotic resistance. Increase in antibiotic use may produce resistance at the individual patient level and an even greater resistance in the population which we may be unable to recover from and increased costs of treatment.
Objectives: To evaluate the patterns of use of antibiotics in tertiary hospital in Kenya for setting appropriate guidelines to promote rational use of antibiotics.
Methods: A retrospective observational study was conducted to evaluate use of antibiotics in tertiary hospital in Kenya January 2020. Primary data was retrieved for a period of eight months between May 2019 to December 2019 from the Pharmacy, laboratory and records department from the facility was reviewed. The study included all out patient prescriptions for which an antimicrobial was prescribed and excluded the inpatient prescriptions. Demographic data such as age, gender and duration of treatment was also collected. Inferential data analysis was done
Results: During that study period 13, 192 patients were seen in the hospital out of these 10,561 (80.1%) prescriptions were written and had at least one antibiotic prescribed. The most commonly used drugs were the β-lactams (penicillin and cephalosporin) 6,310 (59.7%), followed by the Nitro-imidazole 3,203 (30.3%), quinolones 593 (5.6%), macrolides 321 (3.0%) aminoglycosides 135 (1.3%). These antibiotics were mostly used empirically with no culture and sensitivity tests done to inform treatment. According to the evaluation, the use of the antimicrobial therapy was found to be rational in 28% of patients. The average number of antibacterial agents which were prescribed per patient per course of treatment was found to be 3. The Medication related problems identified included: choice of antimicrobial agent, dosage calculation and duration of treatment.
Conclusions: Responsible prescribing guided by guidelines and policies is important to ensure rational use of antibiotics and other antimicrobial agents. In 2017 the Ministry of health in Kenya launched the "national policy on prevention and containment of antimicrobial resistance". This is a great start, all the hospitals in Kenya should form an antimicrobial stewardship team to come up with facility tailored guidelines on antimicrobial use.

4189 | Valproate prescribing practices before and after implementation of risk minimisation measures (RMMs) in 5 European Countries

Massoud Toussi[1], Florence Coste[2], Margarita Shlaen[3], Dimos Vasilis[4] and Sigal Kaplan[5]
[1]*IQVIA, Paris, France;* [2]*Sanofi, Paris, France;* [3]*IQVIA, Munich, Germany;* [4]*DEMO S.A, Attiki, Greece;* [5]*TEVA Pharmaceutical Industries, Netanya, Israel*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Following the Pharmacovigilance Risk Assessment Committee's final recommendations regarding valproate medicines and their use in women of childbearing age (WCBA) (aged 13 to 49 years), label restrictions and RMMs (Direct Healthcare Professional Communication and educational materials) were implemented starting in November 2014 in various European countries. A drug utilisation study was performed by the Marketing Authorization Holders of valproate in Europe to assess the effectiveness of the measures.

Objectives: To describe the prescribing practices before and after the implementation of RMMs

Methods: A multinational non-interventional cohort study was conducted in the outpatient setting using electronic medical records databases (France, Germany, Spain, UK) and national registers (Sweden) based on data recorded from 2012 to 2018. The main outcome was the proportion of valproate initiations preceded by other medications related to valproate indications (mainly epilepsy and bipolar disorder) in women during the main 21-month pre-implementation period and 30-month post-implementation period. Furthermore, the incidence of pregnancies exposed to valproate in WCBA during the entire 36-month pre-implementation period and 36-month post-implementation period of RMMs was investigated.

Results: The proportion of valproate initiations preceded by medications related to valproate indications increased after implementation of RMMs in incident female users in Sweden (from 81.1% to 84.5%) and in UK (from 66.4% to 72.4%), it remained the same in Germany and Spain and decreased in France from 48.7% to 40.6%. In total, 451 and 182 pregnancies exposed to valproate were identified in the entire pre- and post-implementation periods, respectively. In Sweden and UK, where pregnancy data were most interpretable, the incidence of pregnancies exposed to valproate decreased in the post-implementation period: from 9.5 to 8.0 per 1000 person-years in Sweden and from 16.9 to 10.9 in UK.

Conclusions: The effectiveness of RMMs, as measured by change in proportion of valproate initiations preceded by medications related to valproate indications, varied by country (most effective in Sweden and UK and least effective in France). Although the incidence of pregnancies exposed to valproate decreased substantially, the results suggest limited effectiveness of the RMMs. Additional RMMs were implemented in 2018 and an extension study is under way to further monitor the use of valproate in WCBA.

4247 | Use of medication among nursing home residents: A Danish drug utilization study

Carina Lundby[1], John Jensen[2], Søren P. Larsen[2], Helene Hoffmann[2], Anton Pottegård[1] and Mette Reilev[3]

[1]Odense University Hospital, Odense C, Denmark; [2]Type2dialog, Kongens Lyngby, Denmark[3]University of Southern Denmark, Odense C, Denmark

Background: Use of medication with questionable benefit is common among nursing home residents. To facilitate more appropriate medication use and reduce drug-related complications in this vulnerable population, more insight into trends in medication use in relation to nursing home admission is needed.

Objectives: To describe drug use patterns in Danish nursing home residents.

Methods: We established a database of 5,179 individuals (63% women; median age of 84 years) admitted into 94 nursing homes across 11 Danish municipalities during 2015-2017. Data on prescription drug use and other census data were obtained from the nationwide Danish health registries and linked to individual-level data on nursing home admission.

Results: The total number of drug classes filled increased from a median of 6 drugs (interquartile range [IQR] 3-9) at 18-24 months before nursing home admission to a median of 8 drugs (IQR 6-11) just after admission, with the most common drug classes comprising paracetamol (61%), platelet inhibitors (41%), proton pump inhibitors (34%), statins (33%), and potassium supplements (31%). The incidence rate of new drug treatments increased from 21 new treatments/100 residents/month at 12-24 months before admission to a peak of 71 new treatments/100 residents/month in the month prior to admission, while it leveled off to about 34 new treatments/100 residents/month at 6-9 months after admission. The drug classes primarily responsible for this peak were laxatives, antibiotics, and analgesics. The largest absolute increases were seen for laxatives (53%), paracetamol (43%), and antidepressants (36%), all showing a marked increase up to and following admission. A high proportion of residents remained on therapy in the 3-year period following admission, with users of antidepressants and antidementia drugs being most persistent (76-85% still using these drugs after 3 years), followed by users of statins and bisphosphonates (66-70%) and opioids and benzodiazepines (49-58%), respectively.

Conclusions: We found that nursing home admission is associated with an increase in use of both preventive and non-preventive drug classes and that it remains on a level slightly higher than before admission. Although some drug classes may be of questionable benefit in individuals reaching the last years of life, a relatively high persistence to such treatment is common among nursing home residents.

4285 | Adherence and Persistence to Methylphenidate in Children in the Netherlands

Chii Chyi Cheung

Erasmus Medical Center, Rotterdam, Netherlands

Background: Several studies have examined factors that may contribute to adherence or persistence to methylphenidate, but these were mainly conducted in adults and not in children. In children, determinants of adherence and persistence likely differ as information about the family and child characteristics in relation to adherence and persistence to methylphenidate treatment is often limited.

Objectives: To study determinants of adherence and persistence to methylphenidate in children.

Methods: The study was conducted within the Generation R Study, a large population-based cohort study investigating children's health

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

from fetal life onwards in Rotterdam, the Netherlands. The study population included 307 children who all had at least one dispensing record of methylphenidate. Adherence was defined as a medication possession ratio (MPR) of 0.80 or higher and persistence as use until the onset of a continuous discontinuation period of 6 months or longer. Family and child characteristics were tested as determinants of adherence with multivariable logistic regression analysis. Persistence was evaluated using the Kaplan Meier curve.

Results: Children of nulliparous mothers (adjusted OR: 2.31, 95%CI: 1.17-4.54) or mothers with an average household income compared to high income were more likely to be adherent (adjusted OR: 3.45, 95%CI: 1.43-8.31). Girls were more often non-persistent than boys (adjusted HR: 1.44, 95%CI:1.07-1.95) and children who started treatment at age 12-16 were more often non-persistent than younger children (adjusted HR: 3.55, 95%CI:2.54-4.98).

Conclusions: In conclusion, the results of our study showed that not only children but also family characteristics may play a role in treatment adherence. Considering these findings, it is important for healthcare professionals to take these into account when initiating methylphenidate treatment.

4299 | The effect of a pharmacist intervention on guideline adherence for double and triple antithrombotic therapy in a clinical setting

Renate CAE Uden, van
Pharmacy Foundation of Haarlem Hospitals, Haarlem, Netherlands

Background: The use of antithrombotic therapy is a delicate balance between the risk of haemorrhage and thrombotic events. Guidelines on double and triple antithrombotic therapy advise to use this therapy for a limited period of time. A too long continuation exposes a patient to an unnecessary high bleeding risk.

Objectives: To determine the rate of double and triple antithrombotic therapy that is prescribed according to the guidelines in hospitalized patients, and to assess this rate after intervention from a pharmacist.

Methods: Design We performed a prospective intervention study in admitted patients using double or triple antithrombotic therapy. Patients were identified by an algorithm that was implemented in the hospital information system EPIC. Setting The study was performed in three general teaching hospitals in the Netherlands (two cardiovascular intervention centres and a non-intervention centre). The source population were admitted patients that were 18 years or older who used two or more antithrombotic agents, including at least an anticoagulant. Intervention All patients who used double or triple therapy were evaluated on a daily basis whether they had a guideline based indication for the therapy. If not, the pharmacist called the physician and discussed the therapy. Main outcome measures The primary endpoint was the proportion adherence to guidelines prior to intervention. Secondary endpoints were the proportion of patients who had a guideline based indication after intervention and the proportion where the physician intentionally deviated from the guidelines. Statistical analysis Descriptive statistics were used to determine the frequency of double and triple therapy in line with the guidelines. The effect of the intervention was analyzed using a McNemar test.

Results: Of the included 988 patients, 538 patients (54.5%) had a guideline based indication for the prescribed therapy. For 40 patients (4.96%) there was an intentional deviation from the guidelines. For the other patients the pharmacist made an intervention and advised to adjust the therapy. After intervention 922 patients (93.3%) were treated according to the guidelines. The difference in guideline based treatment before and after intervention was significant ($p < 0.0001$).

Conclusions: A considerable proportion of patients treated with double or triple antithrombotic therapy is not treated according to the guidelines. Evaluation of antithrombotic therapy and intervention by a pharmacist is a valuable addition for medication surveillance and may prevent bleeding events.

4304 | Treatment patterns and medication adherence among newly diagnosed migraine patients: A drug utilization study

Sara Mucherino[1], Valentina Orlando[1], Valeria M. Monetti[1], Ugo Trama[2] and Enrica Menditto[1]
[1]*Centre of Pharmacoeconomics, University of Naples Federico II, Naples, Italy, Italy;* [2]*Regional Pharmaceutical Unit, Campania Region, Naples, Italy, Italy*

Background: Guidelines for pharmacological treatment of migraine enlist acute or prophylactic approaches. A few studies are available describing utilization patterns of migraine drugs and adherence to prophylactic treatment.

Objectives: Study aims are: to describe the utilization patterns of migraine drugs at baseline; to evaluate adherence to prophylactic medications; to asses drug-related costs.

Methods: Retrospective population-based study in Primary care setting of Campania Region, Southern Italy. 12,894 subjects with any diagnosis of migraine as primary or secondary hospital discharge or at least 2 medical dispensations of migraine specific acute or prophylactic medication (triptans or pizotifen), were selected from 1 January 2016 to 31 October 2017. Those identified were classified into 4 treatment cohorts (no treatment, acute, prophylactic, both) based on type of migraine medication received, and were analysed (1 year follow-up). Utilization patterns of migraine drugs at baseline and annual drug costs per patient were analysed. Adherence to prophylactic treatment was the main outcome. Differences between patient characteristics were compared using chi-square test for categorical variables or unpaired t test for numerical variables, as appropriate. P value <0.05 was considered significant. Persistence rates were estimated using the Kaplan-Meier method and statistical differences between curves were assessed using Log-rank test.

Results: 81.1% of subjects received acute treatment as their initial therapy, 10.7% prophylactic and 8.2% both. Among those with acute treatment, 53% received triptans, 31.4% NSAIDs. Among those with prophylactic treatment, 31.7% received anticonvulsants. 599 were

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients treated with prophylactic medications. 26.2% were persistent to the initial treatment, while 73.8% interrupted it. Among these, 46.4% fully discontinued the treatment within 103 days (IQR 89.0), 31% restarted it after 46 days (IQR 60.0) from the interruption and 22.6% switched within 98 days (IQR 57.5) (p<0.001). Annual median drug cost was: €103 per patient treated with acute medications, €75 with prophylactic, €163 with both.

Conclusions: In Italian clinical practice migraine treatment with acute medications is still prevalent. A few patients started with prophylactic treatment and persistence was poor. Most of non-persistent patients tended to quit prophylactic therapy within three months from the beginning. These findings reflect an unmet need for improved prophylactic therapies for a better migraine management.

4323 | Adherence and risk factors for stopping treatment in a cohort of Quebec patients newly initiated on statins (OBSTAT cohort)

Sarasa MA Johnson[1,2], Manon Choinière[2,3], Michele Bally[2], Marie-Pierre Dubé[3,2], Jean-Claude Tardif[4], Daniel Gaudet[3], Jean Bergeron[5], Hélène Lanctôt[2] and Jacques Lelorier[1,2,3]

[1]CNODES (Canadian Network of Drug Effect Studies), Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montreal, QC, Canada; [3]Université de Montréal, Montreal, QC, Canada; [4]Centre de Recherche de l'Institut de Cardiologie de Montréal, Montreal, QC, Canada; [5]Centre de Recherche du CHU de Québec Université Laval, Quebec, QC, Canada

Background: Despite the demonstrated effectiveness of statins in reducing risk of cardiovascular events in high risk patients, adherence to treatment remains a barrier.

Objectives: To describe adherence of patients newly initiated on a statin, and identify potential risk factors for stopping treatment.

Methods: Patients newly initiating statin therapy in Montreal, Chicoutimi or Quebec City were invited to participate in this prospective cohort study. At baseline, eligible participants completed questionnaires detailing their personal and familial medical histories, context for statin initiation, lifestyle habits, and biological parameters. Patients were followed at 1, 3, 6, 9, 12, 18, and 24 months where treatment continuation status and potential side effects were recorded. Adherence was defined as taking statins during at least 80% of follow-up. Multivariate cox regression with forward selection was used to identify potential risk factors for stopping treatment.

Results: 1631 new statin-users were enrolled (mean age 57.4 yrs, 47.6% women, mean follow-up time 706.8 days). 33.6% of patients stopped treatment at least once during follow-up. 74.3% of patients were considered adherent. History of pain (HR=1.43), switching statins (HR=1.84) and mention of potential adverse effects by their physician (HR=1.22) increased the likelihood of stopping treatment. Family history of cardiovascular risk (HR=0.64), male gender (HR=0.73), perceiving controlling cholesterol as important (HR=0.49), and living outside Montreal (HR_{Quebec}=0.49, $HR_{Chicoutimi}$=0.81) were considered protective.

Conclusions: Almost three quarters of patients were adherent to treatment. Those who switched statins, had been made aware of potential adverse effects, or who had a history of pain were more likely to stop treatment.

4325 | Trends in fluoroquinolone use in the inpatient and outpatient settings in Nairobi, Kenya: A drug utilisation study

Sylvia A. Opanga, Yvonne L. Isaidi, Antony B. Kodiwo and Joy N. Waithaka

School of Pharmacy, University of Nairobi, Nairobi, Kenya

Background: Fluoroquinolones are used in management of various bacterial infections. Recent pharmacoepidemiological studies have linked them with adverse effects like blood sugar disturbances, aortic dissections, neuropsychiatric effects and tendon disorders, with global regulatory bodies recommending restriction of use.

Objectives: To describe fluoroquinolone prescribing and dispensing patterns in the inpatient and outpatient settings in Nairobi, Kenya.

Methods: A cross sectional study was conducted in the medical and paediatric wards of a leading referral hospital as well as four community pharmacies in Nairobi, Kenya, between April and July 2019. Data was collected through patient interviews and review of medical records and analysed descriptively using SPSS v26. Ethical approval was sought from the University of Nairobi/Kenyatta National Hospital Research and Ethics Committee.

Results: A total of 356 patients were enrolled in the community pharmacies, 115 in the medical wards and 122 in the paediatric wards. In the community pharmacy, the prevalence of fluoroquinolone dispensing was 15%, with ciprofloxacin being the most commonly dispensed. The indications for fluoroquinolone use in the outpatient setting were uncomplicated urinary tract infections (36.4%) and gastrointestinal infections (22.7%). Fluoroquinolones were dispensed over the counter without a prescription in 27% of the cases. In the medical ward, the prevalence of fluoroquinolone use was 13% (n=10), with the most common indication being intra-abdominal infections. In the paediatric ward, 3.8% of the patients were on fluoroquinolones, with the indications being conjunctivitis (75%) and otitis media (25%). In the medical wards and the outpatients, fluoroquinolones were prescribed in the presence of known risks factors of fluoroquinolone adverse effects while in the paediatrics, patients were evaluated for risk factors before prescribing.

Conclusions: Although fluoroquinolone use has dropped after regulatory restrictions, patients in the medical wards and outpatient settings were not screened for risk factors of developing fluoroquinolone adverse effects. Some outpatients received the drugs without a prescription. Regulation of community pharmacies is required to ensure adherence to fluoroquinolone dispensing policies. Assessment of patients for risk of adverse effects from fluoroquinolones should be done.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4375 | Adverse events related to overtreatment for hypertension in type 2 diabetes patients: impact of age and polypharmacy

Martina Ambrož[1], Sieta T. de Vries[1], Klaas Hoogenberg[2] and Petra Denig[1]

[1]*University of Groningen, University Medical Center Groningen, Groningen, Netherlands;* [2]*Martini Hospital, Groningen, Netherlands*

Background: Overtreatment for hypertension can lead to unwanted outcomes in people with type 2 diabetes (T2D). Too strict systolic blood pressure (SBP) targets may increase the risk of adverse events (AEs), particularly in older patients or patients with polypharmacy.

Objectives: To assess whether age and polypharmacy have an impact on the occurrence of AEs related to low SBP levels in T2D patients treated with antihypertensives.

Methods: We conducted a cross-sectional study using data from the Groningen Initiative to Analyze Type 2 diabetes Treatment (GIANTT) database, which includes primary care T2D patients from the north of the Netherlands. Included patients received chronic treatment with antihypertensive medication in 2012, were >18 years and had at least 1 SBP measurement in this year. The outcome was the occurrence of hypotension-related AEs. Determinants were low SBP level (<130 mmHg), older age (≥80 years), polypharmacy (5-9 or ≥10 drugs), and the interactions between age or polypharmacy and SBP. We conducted logistic regression analyses adjusted for confounders, such as sex, diabetes duration, diastolic blood pressure, and other risk factor levels, and present Odds Ratios (OR) with 95% Confidence Intervals (CI) for the effect of age or polypharmacy on AEs, and for their interaction with a low SBP level.

Results: We included 16,219 patients, 52% of which were females. In total, 16% were aged 80 years or older, 56% used 5-9 drugs and 30% used ≥10 drugs. The average SBP was 143 mmHg (SD 16), with a median number of antihypertensives of 2 (IQR 1-3). AEs were seen for 5.8% of patients with an SBP<130 mmHg and 5.0% of patients with an SPB≥130 mmHg. In older patients with an SBP<130 mmHg this was 8.3%; for polypharmacy (5-9 or ≥10 drugs) this was 4.7% or 9.2%, respectively. Both older age (OR 1.60, 95%CI 1.35-1.89) and polypharmacy (5-9 drugs: OR 2.13, 95%CI 1.56-2.92; ≥10 drugs OR 4.75, 95%CI 3.48-6.48) showed a significant association with the occurrence of AEs. The interactions were not statistically significant (p=0.61 for interaction with age; p=0.17 and p=0.27 for interactions with polypharmacy).

Conclusions: Prevention of overtreatment for hypertension needs attention in T2D patients who are older or have polypharmacy, since both are potential risk factors for hypotension-related AEs in T2D patients treated with antihypertensives. We found no evidence, however, that these factors enhance the risk of low SBP levels on hypotension-related AEs.

4455 | The comparison of drug use in children and adults with allergy in primary care

Volkan Aydin[1], N Ipek Kirmizi[2], Omer Atac[2], Narin Akici[3] and Ahmet Akici[1]

[1]*Marmara University, Istanbul, Turkey;* [2]*Istanbul Medipol University, Istanbul, Turkey;* [3]*Haydarpaşa Numune Training and Research Hospital, Istanbul, Turkey*

Background: As a common condition encountered in primary care, allergy is managed with a variety of different medications depending on wide spectrum of its clinical picture.

Objectives: We aimed to compare drug use of allergic children and adults in primary care.

Methods: We reviewed prescriptions of pediatric (<18-year-old) and adult (≥18-year-old) patients with single"allergy, unspecified (ICD Code: T78.4)" diagnosis in primary care centers of Istanbul province in 2016 (n=37,042). The details of drug utilization were compared in these groups.

Results: Over half of the prescriptions (55.9%) belonged to adult population. We identified the mean age of the children and adults as 6.7 ±4.5 and 47.3±17.8 years, respectively. The percentage of female patients were lower in children (47.6%) than that in adults (67.7%), (p<0.0001). "R-Respiratory system" drugs constituted the most commonly used drugs in children (61.2%) and adults (51.8%). Among all drugs, desloratadine was the most frequently prescribed drug, followed by cetirizine both in children (21.2% and 16.2%, respectively) and adults (10.3% and 7.7%, respectively). Children had higher percentage of prescriptions with topical medication (51.7% vs 42.7%, p<0.0001) whereas adults had higher percentage of prescriptions with systemic antihistamines (85.3% vs. 83.4, p<0.0001) and systemic corticosteroids (5.4% vs. 1.6%, p<0.0001) compared to their counterparts. The percentages of prescriptions with systemic anti-infectives were similar in children (6.4%) and adults (6.7%), (p>0.05).

Conclusions: This study shows an antihistamine-based pharmacotherapy in primary care management of allergy both in children and adults. While main drug classes preferred in this indication seem similar, their utilization rates exhibit differences between children and adults.

4518 | Qualitative assessment of special instructions or warnings provided to patients prescribed a nitrate with a concurrent contraindicated medication

Anthony P. Nunes[1,2], Andrew Stewart[3], Alankar Gupta[3], Thomas McGraw[3], Jennifer Song[2] and John D. Seeger[2]

[1]*University of Massachusetts Medical School, Boston, MA;*[2]*Optum Epidemiology, Boston, MA;*[3]*Sanofi, Boston, MA*

Background: Clinical notes complement the prescription record by documenting anticipated dosing frequency and instructions or warnings regarding use. This added information is enhances assessment of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

potentially inappropriate exposure, such as concurrent contraindicated medications.

Objectives: To assess and describe EHR documentation of special instructions and/or warnings provided to patients who were prescribed a nitrate with a current contraindicated medication.

Methods: Within the Optum electronic health record (EHR) data (2012 to 2016), we identified patients with any nitrate prescription and also those with a concurrent contraindicated prescription. We used natural language processing (NLP) to identify patients with at least one note mentioning nitrates or the contraindicated drug. We reviewed a sample of 250 patient profiles (chronological listings of EHR data), and deidentified source clinical notes. The patient profiles were reviewed and categorized according to whether there was evidence of special instructions or warnings. Major themes were identified and summarized.

Results: Overall, 131 (52%) of the 252 of the reviewed patient profiles contained documentation that patients had discussions with their physician during their co-possession period. Just over half contained a direct warning against using both medications together or advice to discontinue one of the medications. Upon review of the deidentified source clinical note, the following themes were identified (1) nitrate prescribed with a warning and guidance to defer use until contraindicated drug is discontinued (2) nitrate prescribed concurrent with contraindicated medication due to infrequent nitrate use, and (3) nitrate prescribed without EHR documentation of any warning or special instructions. Examples of observed warnings include: "We discussed drug interactions, particularly with nitrates. He was warned not to take nitroglycerin with his medication", and "He does carry nitroglycerin but has not used it in the past 10 years… he was warned about possible interaction with nitroglycerin." Additional examples will be provided.

Conclusions: We observed that clinicians were often aware of nitrate contraindications, and documented awareness, circumstances, patient characteristics, anticipated use, and ability to manage the contraindication. By adding NLP and free text note review as a supplement to structured data elements from the prescription record, we may better understand the potential for contraindicated exposures.

4611 | Assessment of World Health Organisation core drug use indicators in tertiary care hospital of Kathmandu, Nepal: A cross-sectional study

Rakesh Ghimire[1], Bijay Bhandari[1], Nirmal Poudel[2], Sandesh Pradhan[2] and Shristi Kharel[3]

[1]Institute of Medicine, kathmandu, Nepal; [2]Institute of Medicine, kathmandu, Nepal; [3]Himal Hospital, kathmandu, Nepal

Background: Inappropriate drug use has serious health and economic influences for the success of national health care system. Promoting the rational use of drug can provide better health and medical care to patients and to the community as a whole. A number of indicators have been developed, standardized and evaluated by the World Health Organization (WHO) to assess the rational use of the drug. The three core drug indicators are prescribing indicators, patient care indicators and facility indicators.

Objectives: The aim of the present study was to assess WHO core drug use indicators at Tribhuvan University Teaching Hospital (TUTH), a tertiary care hospital of Kathmandu, Nepal

Methods: A prospective cross-sectional study on WHO core drug use indicators was done at one of the biggest referral centres of Nepal. Data were collected using standard prescribing, patient care and facility-specific indicator forms. Reliability of the data was ensured by following the WHO guidelines and methods. A total of 300 encounters were investigated and simple descriptive analysis was done.

Results: The average number of drugs per prescription was 8.59 and 16.87% of the medicines were prescribed by generic name. Prescriptions containing antibiotics and that of injectable were 22.3% and 1.6% respectively. The percentage of the drugs prescribed on the essential drug list was 16.43. The average consultation was found to be 13.30 minutes and dispensing time was 192.05 seconds. Furthermore, 69.35% of the prescribed drugs were actually dispensed. None of the prescriptions was adequately labelled and 85% of patients know about the dosage of the prescription. The hospital has a copy of the national list of essential medicines-Nepal. However, the hospital doesn't have a list of key drugs.

Conclusions: The study concluded that polypharmacy and the number of drugs prescribed by brand names were common. The doctors spending time to a patient was found to be higher than the WHO standard. The study warrants the need for hospital's standard treatment guidelines and availability of key drugs.

4675 | Inappropriate drug therapy prescription in older outpatients in Italy

Federica Galimberti[1], Manuela Casula[1,2], Elena Olmastroni[1], Veronica Russo[3], Enrica Menditto[3], Alberico L. Catapano[1,2] and Elena Tragni[1]

[1]University of Milan, Department of Pharmacological and Biomolecular Sciences, Epidemiology and Preventive Pharmacology Service (SEFAP), Milan, Italy; [2]IRCCS MultiMedica, Sesto S. Giovanni (MI), Italy; [3]CIRFF - Department of Pharmacy, University of Naples Federico II, Naples, Italy

Background: Pharmacological intervention is an essential step in health promotion. However, the process of setting a diagnosis and choosing appropriate drug treatment is complex and lots of drugs are often prescribed and used in inappropriate ways, especially in older patients.

Objectives: The aim of this study was to retrospectively evaluate prevalence of potential inappropriate prescribing in community-dwelling elderly population in Italy.

Methods: This analysis was based on baseline data from the EDU.RE.DRUG (*Effectiveness of informative and educational interventions aimed at improving the appropriate use of drugs designed for general practitioners and their patients*) project, that was funded by the Italian Medicines Agency and included all GPs and their adult patients (≥40 years)

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

from 8 local health units (LHUs) in Campania and Lombardy regions. We defined a set of explicit indicators for potential inappropriate prescription, including polypharmacy, potential drug-drug interactions (pDDIs) and drugs to be avoided in the elderly according to the ERD list [EDU.RE.DRUG list], which is based on validated Beers, STOPP and EU(7)PIM criteria, and adapted to the Italian drug formulary. Using administrative healthcare databases from the involved LHUs, we retrospectively assessed the annual prevalence rates of the selected indicators during the period 2014-2016 among subjects aged ≥65 years.

Results: We observed high rates of polypharmacy in both the regions. About one out of three older patients in Lombardy LHUs received 5 to 9 drugs compared one in two in Campania LHUs; hyper-polypharmacy (≥10 drugs) ranged from 5 to 9% and from 18 to 25%, respectively. Around 25-35% in Lombardy and 50-65% in Campania were prescribed at least one inappropriate drug included in the ERD-list; among them proton pump inhibitors (used for more than 8 weeks) and NSAIDs (i.e. ketoprofen and diclofenac) represented the most frequently occurred ERD-list criteria. Furthermore, 18-27% of older patients in Lombardy were exposed to at least one pDDI, while in Campania this percentage was even higher (35-43%). The most frequent pDDIs were hydrochlorothiazide-ibuprofen and pantoprazole-levothyroxine in Lombardy, and hydrochlorothiazide-diclofenac in Campania for the 3 years considered.

Conclusions: Despite some remarkable geographical differences, these results highlight a widespread need for intervention to improve the quality of prescribing in primary care setting in Italy. Moreover, the tools provided to identify patients at higher risk of medicine-related problems based on Italian drug-utilization patterns will be also adaptable to other national contexts.

4689 | Differential missingness of antibiotic indications in claims data

Paula D Strassle, Rachael K Ross, Ashley H Marx, Zachary I Willis, Claire E Farel and Alan K Kinlaw
University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Indication is critical in identifying opportunities for antibiotic stewardship and to control confounding in health outcomes analyses. Studies in claims data regularly use outpatient service records to identify indications for dispensed prescriptions; however, little is known about how identifying indications vary across antibiotic classes or individual characteristics.

Objectives: To estimate prevalence of unknown indication in antibiotic fills and examine variability of missingness across antibiotic class, patient subgroups, and insurance plan types.

Methods: We identified all oral, systemic antibiotic prescription fills from individuals age <65 years in IBM Watson Health MarketScan data (2017-2018). 60 days of pre-fill and 7 days post-fill insurance coverage was required. Indications were classified based on need for antibiotic treatment: "almost always", "sometimes", and "not indicated" using classification scheme developed by Fleming-Dutra et al. (doi 10.1001/jama.2016.4151) using outpatient claims 7 days prior through 7 days after the fill. We grouped antibiotics by Anatomical Therapeutic Chemical codes. Multivariable binomial regression was used to estimate prevalence differences (PD) for unknown indication data by demographic characteristics, prior antibiotic use, prior inpatient admission, antibiotic class, and season. Repeated observations were handled with generalized estimating equations with compound symmetric correlation structure. All 95% confidence limits were within 0.01 of PD estimates and thus not presented.

Results: Overall, 30,306,593 antibiotic fills (12,642,528 unique individuals) were included. Penicillins (36%), macrolides (19%), and tetracyclines (11%) were most common. 49% of antibiotic fills only had "not indicated" diagnoses (28%) or no healthcare claims (21%) during the measurement window. Unknown indication was more prevalent in adults than children (PD 0.21). Compared to penicillins, unknown indication was more common for lincosamides (PD 0.13), macrolides (PD 0.10), 1st generation cephalosporins (PD 0.09) and tetracyclines (PD 0.07), and less common for oxazolidinones (PD -0.14), 2nd/3rd generation cephalosporins (PD -0.09), and sulfonamides/trimethoprim (PD -0.05). Gender, prior antibiotic use, and prior hospitalization had minimal impact.

Conclusions: In this privately insured population, half of antibiotic fills lacked supporting claims data on relevant indication for antibiotics; moreover, unknown indication differed by antibiotic class and age. Future claims-based studies of antibiotics should regularly address missing data on indication.

4712 | Utilization of rotigotine transdermal patch in Germany: results from a claims database study

Lars Joeres[1], Stephan Luca[2], Guilhem Pietri[3] and Lisa Zimmermann[4]
[1]*UCB Biosciences GmbH, Monheim, Germany;* [2]*UCB Pharma GmbH, Monheim, Germany;* [3]*Data Pyxis Ltd, Stevenage, United Kingdom;* [4]*Gesundheitsforen Leipzig GmbH, Leipzig, Germany*

Background: Rotigotine (RTG), a dopamine agonist, is authorized in EU as a transdermal patch for the treatment of Parkinson's disease (PD) and restless legs syndrome (RLS) with a recommended dose ranging from 4 to 16mg/24h for PD and 1-3mg/24h for RLS. Data on real-life usage of RTG in Germany are not available.

Objectives: To assess utilization and persistence (overall and dose-dependent) of RTG for RLS and PD in real-world practice in Germany.

Methods: Utilization and persistence of RTG among prevalent PD and RLS patients were assessed between 2013 and 2017 using the Deutsche Analysedatenbank, a collection of claims data from German sick funds, according to ICD-10 and ATC codes. Annual prevalence rates were calculated for PD and RLS and extrapolated to the German social health insured (SHI) population. RTG utilization in prevalent PD and RLS patients was assessed as number of treated patients, mean and median dosage per indication; persistence was assessed as mean

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

treatment duration (in days) overall and per dosage. Summary descriptive statistics were calculated.

Results: Approx. 2 million insured persons could be evaluated. Among those, 9,876 (PD) and 16,617 (RLS) patients could be identified using G20.0, G20.1, G20.2, G20.9 ICD-10 codes for PD and G25.80, G25.81 and G25.88 for RLS (extrapolated to 291,026 PD and 489,669 RLS patients in the SHI population). Of those, 543 PD patients and 699 RLS patients claimed at least one prescription of RTG (ATC code N04BC09; extrapolated to 16,001 PD and 20,598 RLS patients). A mean dose of 4.88mg/24h in PD and 2.58mg/24h in RLS was calculated. Dosages of 2, 4, 6, and 8mg/24h in PD and 1, 2, 3mg/24h in RLS were mainly used (29.7%, 33.7%, 23.6%, and 23.6% of PD patients were treated with RTG 2mg, 4mg, 6mg, and 8mg, respectively; 34.8%, 42.6% and 28.5% of RLS patients were treated with RTG 1mg, 2mg and 3mg, respectively), reflecting the commercially available patch sizes. Persistence overall was calculated as 218.3 days in PD and 391.1 days in RLS. The persistence in PD for stable doses of 4 - 6mg/24h ranged from 136.1 to 122.2 days; the highest persistence was observed in PD at 8mg/24h with 322.5 days. In RLS, persistence ranged from 522.0 to 343.1 days within approved dose range of 1-3mg/24h.

Conclusions: The analysis suggests that RTG is prescribed according to prescribing recommendations but using a lower recommended dose range for PD. Mean dose for RTG in PD was in a lower dose range. Persistence is higher for RLS and equally distributed among approved dosages but for PD persistence appears to be dose-dependent, with highest persistence at 8mg/24h. Further research needs to be conducted to corroborate the findings.

4779 | Real-world therapeutic management of stroke survivors with atrial fibrillation, predictors, and clinical outcomes

A Population-based Cohort

Clara Liliana Rodríguez-Bernal, Daniel Bejarano-Quisoboni, Isabel Hurtado, Anibal Garcia-Sempere, Salvador Peiró and Gabriel Sanfelix-Gimeno FISABIO, Valencia, Spain

Background: In stroke survivors with atrial fibrillation (AF), physicians have to weigh the risk-benefit of preventing recurrence of stroke while avoiding hemorrhagic events, working with guidelines that are based on consensus (instead of empirical evidence).

Objectives: To assess patterns of therapeutic management of stroke survivors with atrial fibrillation, predictors of treatment at discharge and clinical outcomes using data from routine practice.

Methods: Population-based retrospective cohort study. All patients with a previous diagnosis of AF, discharged alive after hospitalization for an acute ischemic stroke or TIA in the Valencia region from Jan 2010 to Dec 2015. Data were obtained from the Valencia Health System (VHS) Integrated Databases (VID), covering 97% of the population of the Region (5 million inhabitants, ≈12% of the Spanish population). Treatment strategies at discharge (no antithrombotic treatment, antiplatelets- APT, oral anticoagulants-OAC or OAC+APT) and their predictors are described as well as incidence rates of clinical outcomes (gastrointestinal bleeding, stroke/TIA, acute coronary syndrome-ACS- and death) according to treatment decisions.

Results: Of the 8084 patients with AF, discharged alive after a stroke, 847 (10.5%) did not receive antithrombotic treatment within 1month, 2323 (28.7%) were prescribed APT, 3496 (43.3%) OAC and 1418 (17.5%) OAC+APT. Regarding predictors of treatment strategy, overall, being older, female, having chronic heart failure, dementia, malignancy and previous GI and intracranial bleeding were associated to being untreated or treated with APT only. History of coronary heart disease was one of the strongest predictors of being treated with APT, alone or in combination. Overall, previous treatment with the different strategies was a strong predictor of post-discharge treatment decisions. Regarding clinical outcomes, patients treated with APT only had the highest incidence of GI bleeding (18.6 per 1000 person-years) and recurrent stroke/TIA (91.8 per 1000 p-y) while those untreated had the highest incidence of death (523.1 per 1000 p-y). Patients treated with OAC+APT showed the highest incidence of ACS (13.7 per 1000 p-y).

Conclusions: In this large population-based cohort of patients with AF who suffered a stroke, we found that although the most common treatment strategy at discharge was OAC therapy, almost one third were treated with APT only. Untreated patients and patients treated with APT only had an increased risk of adverse clinical outcomes, probably due to their clinical profile.

4785 | Appropriateness of outpatient antibiotic prescribing in china: nationwide cross-sectional study

Houyu Zhao[1], Jiaming Bian[2] and Siyan Zhan[1]

[1]*Peking University, Beijing, China;* [2]*The 7th Medical Center of the Chinese PLA General Hospital, Beijing, China*

Background: Little is known about the appropriateness of outpatient antibiotic prescribing at the national level in China, where antibiotic consumption is very high.

Objectives: To estimate the antibiotic prescription rates for common diagnosis categories and to assess the appropriateness of outpatient antibiotic prescriptions for all conditions and all ages in China.

Methods: A data of 172.7 million outpatient and emergency department visits from 139 secondary- and tertiary-level hospitals in 28 provinces of Mainland China from October 2014 to April 2018 were analyzed. Prescription diagnoses were classified as being appropriate, potentially appropriate, inappropriate, or not linked to any diagnosis for antibiotic use by following a published classification scheme. Antibiotic prescription rates for various diagnosis categories and proportions of inappropriate antibiotic prescribing for different subgroups were estimated. Antibiotic prescribing pattern and proportions of individual antibiotics prescribing for different diagnosis categories were analyzed and reported.

Results: Among the 172704117 outpatient visits, 18848864 (10.9%) were prescribed at least one antibiotic. For conditions that antibiotic

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

use is almost always appropriate, potentially appropriate, and almost always inappropriate, 42.2%, 30.6%, and 7.6% visits ended with antibiotic prescriptions. Among all 18848864 antibiotic prescriptions, 9 689 937 (51.4%) were inappropriate, 5354224 (28.4%) were potentially appropriate, 2893102 (15.3%) were appropriate, and 911601 (4.8%) could not be linked to any diagnosis. Among these 18848864 antibiotic prescriptions, a total of 23266533 individual antibiotics were prescribed, the top three most prescribed antibiotics were cefdinir (2121584, 9.1%), followed by levofloxacin (2027757, 8.7%), and azithromycin (2010669, 8.6%).

Conclusions: In Chinese secondary- and tertiary-level hospitals, over half of antibiotic prescriptions were inappropriate, suggesting an urgent need of outpatient antibiotic stewardship aiming at reducing inappropriate antibiotic prescribing to achieve the goals set in the Global Action Plan and National Action Plan.

4805 | Use of adjusted sequence symmetry analysis to quantify the impact of a new diagnosis on off-label prescribing: A case example with NAFLD and pioglitazone

Anthony P. Nunes, Danni Zhao and Matthew J. Alcusky
University of Massachusetts Medical School, Worcester, MA

Background: Sequence symmetry analysis (SSA) has historically been used to identify adverse event signals. This approach relies on the temporal relationship between two incident events to quantify the association between an exposure and outcome. SSA may be an efficient means of identifying clinical responses to new diagnoses, including off-label prescribing of medications.

Objectives: We employ an adjusted SSA to quantify the extent to which a new diagnosis may increase off-label prescribing of a drug, using pioglitazone and NAFLD as the applied example.

Methods: We identified patients with a new diagnosis of NAFLD and an initiation of pioglitazone (from dispensing claims) from 2012 to 2019 in the MarketScan® Explorys® Claims- EMR Data Set. We defined 3, 6, and 12-month windows preceding and following the NAFLD date and created indicators of presence or absence of pioglitazone initiation within these windows. Analyses were limited to patients with a pioglitazone initiation in either the preceding or following window. A control was created by generating a random date representing a pseudo-pioglitazone initiation and categorizing the pseudo initiation date as described for the actual initiation date. The final adjusted effect estimate was obtained via conditional logistic regression modeling, with the independent variable being the exposure indicator (actual or pseudo pioglitazone initiation vs no initiation) and the dependent variables being the analysis indicator (actual vs pseudo pioglitazone initiation) and the interaction between the analysis indicator and NAFLD indicator (NAFLD=1 if exposure observed in follow-up window or 0 if observed in preceding window). The parameter estimate for the interaction term served as our estimate of the increased odds of initiating pioglitazone due to a new NAFLD diagnosis.

Results: We identified 350 eligible patients. Of these, 110 were included in the analysis of the 3-month window, 183 for the 6-month window, and 350 for the 12-month window. Crude odds ratios and 95% confidence intervals were 1.00 (1.69-1.45), 1.18 (0.88-1.58), and 1.59 (1.28-1.98) for 3, 6, and 12-month analyses respectively. Adjusted odds ratios were attenuated to 0.96 (0.80-1.15), 1.14 (0.99-1.32), and 1.42 (1.27-1.59) for corresponding analyses.

Conclusions: SSA is an efficient means of estimating the effect of a new diagnosis on subsequent off-label drug initiation. In our case example, there was no evidence of an immediate response, though there may be a shift towards initiating pioglitazone as we expand the observation window beyond 6-months.

4819 | Antipsychotics used to treat patients with severe mental disorder in outpatient follow-up at a psychiatric hospital

Ronaldo Portela[1], Cristina M. Ruas[1], Helian N. Oliveira[2] and Mariana D. Lula[1]
[1]*Federal University of Minas Gerais, Belo Horizonte, Brazil;* [2]*Federal University of Minas Gerais, Belo Horizonte, Brazil*

Background: Although antipsychotics are frequently used by patients diagnosed with severe mental disorder, few studies have been conducted to characterize outpatient treatment in psychiatric hospitals.

Objectives: To evaluate the use of antipsychotropic drugs divided into three groups (typical, atypical and long-acting injectables).

Methods: It is an observational cohort review study of 625 patients' medical records. The study included patients diagnosed with severe and persistent mental disorder who received their first hospital discharge from January to December 2012 and continued maintenance treatment at the hospital until December 2017. Descriptive statistical analyzes were performed to evaluate sociodemographic and clinical characteristics. In the descriptive analysis of categorical variables, absolute and relative frequencies were used and for quantitative variables, measures of position, central tendency and dispersion were used.

Results: Most patients are male (51.5%) with an average age of 37 (± 11) years. Patients have an average of 1.7 (± 1.5) children. The age of the first psychotic break was at 23 (± 8.3) years. The percentage of suicide attempt was 11.0% (± 1.4), with the majority being 60.9% female. Most patients (82.9%) did not use associated antipsychotics. The majority (65.8%) adhered to the treatment and 13.9% reported that they interrupted it due to the lack of the drug in public pharmacies. There was a need to change the antipsychotic due to the lack of therapeutic response for 11.2% of the patients and for 5.3% due to the adverse reaction to the antipsychotic used. The group of typical antipsychotics was the most used (62.9%), with haloperidol (54.3%) being the most prescribed.

Conclusions: Contrary to other studies, the percentage of male patients with severe mental disorders is not significantly higher than that of females. It is observed in the study that the association of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

antipsychotics in out-of-hospital treatment is low. The study confirms that non-adherence to treatment, difficulty in accessing the medication, as well as its profile of therapeutic response and adverse reactions are determining factors in the assessment of outpatient treatment. In contrast to other studies that demonstrate a growing option for the use of atypical antipsychotics and long-acting injectables, it is observed in the present study that typical antipsychotics, especially haloperidol, are still the most used.

4827 | Prevalence and characteristics of adverse drug reaction-related hospital admissions in older Patients

Caitriona Cahir[1], Carmel Curran[2], Caroline Walsh[1], David J Williams[2] and Kathleen Bennett[1]
[1]*Royal College of Surgeons in Ireland, Dublin, Ireland;* [2]*Beaumont Hospital, Dublin, Ireland*

Background: Older people experience greater morbidity with a corresponding increase in medication use resulting in a potentially higher risk of adverse drug reactions (ADRs).
Objectives: The aim of this study was to determine the prevalence and characteristics of ADR-related hospital admissions among older patients (≥ 65 years).
Methods: A cross-sectional study of ADR prevalence in patients aged ≥ 65 years admitted acutely to a large tertiary referral hospital in Ireland over a 7 month period (November 2016- June 2017). A multifaceted review of each hospital admission was undertaken to assess the likelihood of an ADR being a reason for admission (cause of admission or contributing to admission) in the context of the patient's medication, clinical condition, medical history, comorbidities and investigations. A number of decision aids were applied by two independent reviewers to assess ADR causality (Naranjo criteria, WHO criteria, Liverpool Algorithm). The avoidability (Hallas criteria) and severity (Hartwig severity assessment scale) of the ADR were also assessed. Differences in causality, preventability and severity were reviewed by a third reviewer.
Results: In total, 3760 hospital admission episodes (in 3091 patients) were screened and 377 admissions were ADR-related (10.0 %, 95% CI 9.1%, 11.0%); 43 admissions were due to ≥2 ADRs (N= 424 ADRs). 360 (11.6% 95% CI 10.5%, 12.8%) patients had at least one ADR with 50 (16.2%) patients experiencing ≥ 1 ADR-related admission. In summary, 219 (58.1%) admissions were caused by an ADR, while ADRs contributed to 158 (41.9%) admissions. For the majority of admissions (N= 216, 57.6%) there was no other known acute medical issue that may have acted in synergy with the medication resulting in the ADR. Of the 377 ADR-related admissions, 43 (11.4%) were deemed definitely avoidable and 225 (59.7%) possibly avoidable and 350 (92.8%) were classified as moderate severity.
Conclusions: One in ten hospital admissions were ADR-related, with approximately 70% potentially avoidable. Interventions are needed to reduce ADRs and improve medication management in older populations.

4834 | Pharmacological treatment of insomnia in general practice

Mette H Bakker[1], Nina A Oldejans[1], Henriëtte E van der Horst[1], Jacqueline G Hugtenburg[2] and Pauline Slottje[1]
[1]*Amsterdam UMC, location VUmc, Amsterdam, Netherlands;* [2]*Amsterdam UMC, location VUmc, Amsterdam, Netherlands*

Background: According to the Dutch general practitioners guideline for insomnia, insomnia should initially be treated with non-pharmacological treatment. Only in an acute crisis or if non-drug treatment not leads to improvement, short-acting benzodiazepines or Z drugs may be used to a limited extent. Adherence to this guideline has not been studied as yet.
Objectives: The aim of this study was to gain insight into the current pharmacological treatment of insomnia in Dutch general practice.
Methods: Anonymized electronic medical records from 20 Dutch general practices covering the period between 01/01/2013 and 01/01/2018 were derived from a pseudonymized general practice database. The study comprised 1,125 adults with insomnia diagnosed after the publishing date of the current guideline (01/07/2014) who could be prospectively followed for two years after diagnosis. Free text documentation was reviewed by three instructed researchers using a scoring protocol and combined with structured data for descriptive analysis.
Results: Preliminary results show that 82% of patients were prescribed sleep medication the first two years after diagnosis. Nearly a quarter of these patients were found to have used up to 6 agents. Less than 10% of the patients appeared to have received non-pharmacological treatment prior to the prescription of sleep medication. For about 50% of patients pharmacological treatment consisted of a short-acting benzodiazepine, whereas about 15% were treated with another benzodiazepine and almost 25% with other (off-label) agents.
Conclusions: Sleep medication was often prescribed in the first two years after the diagnosis of insomnia. Only in a small part of patients non-drug treatment preceded the prescribing of sleep medication. Off-label sleep medication and benzodiazepine other than recommended by the guideline are regularly prescribed. Moreover, different agents were used in a large number of patients.

4840 | Prevalence and predictors of potential drug-drug interactions in an older community-based population

John Hughes[1], Kathleen Bennett[1], Veronica Russo[2], Caroline Walsh[1], Enrica Menditto[3] and Caitriona Cahir[1]
[1]*Royal College of Surgeons in Ireland, Dublin, Ireland;* [2]*University of Naples Federico II, Naples, Italy;* [3]*University of Naples Federico II, Naples, Italy*

Background: Multimorbidity, commonly defined as the co-existence of two or more chronic conditions, affects almost three-quarters of adults aged ≥ 65 years. Older people are often prescribed multiple

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

medications to manage their chronic conditions which increase an individual's risk of experiencing a drug-drug interaction (DDI).

Objectives: The aim of this study was to: (1) determine the prevalence of potentially severe cardiovascular and central nervous system (CNS) DDIs and; (2) examine potential predictors of any DDIs in a cohort of community-dwelling older adults.

Methods: A prospective cohort study (aged ≥ 70 years), using linked data from a national pharmacy claims database and Waves 1 & 2 of The Irish LongituDinal study on Ageing (TILDA). 'Severe' cardiovascular and CNS DDIs were first identified using the BNF 77. These were then cross-referenced using Stockley's Drug Interactions and drug combinations identified as being contraindicated or requiring close monitoring were included. Prevalence was calculated as the presence of any DDI out of all eligible participants. A chronic DDI was defined as ≥ 3 consecutive months of dispensed medication with the same DDI. Logistic regression was used to examine participant-level risk factors associated with the risk of a DDI between Waves 1 & 2 and included age, gender, marital status, education, smoking status, number of chronic conditions, poor delayed recall, depression, frailty and polypharmacy. Adjusted odds ratios (OR) and 95% CIs are presented.

Results: In total, 1,466 patients were included (mean age=78 SD=5.5; Female N=795, 54.2%). The overall prevalence of DDIs was 29.6% (N=434); 210 (48%) of these patients had a chronic DDI. The prevalence of DDIs per claim was 14.4% (N=33,548 claims). Aspirin and warfarin were the most frequently prescribed DDI per prescription claim (N=217, 4.5%), followed by ramipril and allopurinol (N=214, 4.4%). Polypharmacy (≥ 10 drugs) (OR=29.2; 95% CI 9.1, 93.5), frailty (OR=1.7; 95% CI 1.1, 2.7), smoking history (OR=1.3; 95% CI 1.0, 1.8) and depression (OR=1.7; 95% CI 1.1, 2.6) were significantly associated with experiencing a DDI.

Conclusions: DDIs are highly prevalent in older people and frail patients with polypharmacy require regular medication reviews and prescribing optimisation

4851 | Agreement between self-reported morbidity and pharmacy claims data for prescribed medications in a community based population

Clionadh Mannion[1], John Hughes[2], Frank Moriarty[2], Kathleen Bennett[2] and Caitriona Cahir[2]

[1]Trinity College Dublin, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland

Background: Studies have indicated variability around prevalence estimates of multimorbidity due to poor consensus regarding its definition and measurement. Medication-based measures of morbidity may be valuable resources in the community-care setting where access to medical data can be limited.

Objectives: To compare the agreement between patient self-reported and medication-based morbidity and examine potential patient-level predictors of discordance between these two measures of morbidity in a community-based population.

Methods: A retrospective cohort study (aged ≥ 50 years) using national pharmacy claims data linked to The Irish LongituDinal study on Ageing (TILDA). Morbidity was measured by patient self-report (TILDA) and two medication-based measures, the Rx-Risk (< 65 years) and Rx-Risk-V (≥ 65 years), which classify drug claims into chronic disease classes. The kappa(κ) statistic measured agreement between patient self-reported and medication-based morbidity at the individual level. Multivariate logistic regression was used to examine patient-level characteristics associated with discordance between measures of morbidity with odds ratios (OR) and 95% CI presented.

Results: In total 2,925 patients were included (<65 years: N=1,095, 37.4%; and ≥ 65 years: N=1,830 62.6%). Hypertension and high cholesterol were the most prevalent self-reported morbidities in both age cohorts. Agreement was good or very good (κ=0.61-0.81) for diabetes, osteoporosis and glaucoma; and moderate for high cholesterol, asthma, Parkinson's and angina (κ=0.44-0.56). All other conditions had fair or poor agreement. Age, gender, marital status, education, poor-delayed recall, depression and polypharmacy were significantly associated with discordance between morbidity measures (p<0.05).

Conclusions: Most conditions achieved only moderate or fair agreement between self-reported and medication-based morbidity. The current Rx-Risk and Rx-Risk-V require updating to assess their true reliability and validity as medication-based measures of morbidity.

4922 | Bacterial isolates and their patterns of antibiotic resistance in the critical care unit of a national referral hospital in Kenya

Emmah B. Obegi[1], Margaret N. Oluka[2], Sylvia A. Opanga[3] and Faith A. Okalebo[2]

[1]University of Nairobi, Nairobi, Kenya; [2]University of Nairobi, Nairobi, Kenya; [3]University of Nairobi, Nairobi, Kenya

Background: Critically ill patients have a high risk of developing life-threatening infections. The extensive and indiscriminate use of antimicrobials in the critical care unit leads to selective pressure for resistant bacteria.

Objectives: To determine the commonest micro-organisms isolated from patients admitted in the Critical Care Unit and their susceptibility patterns.

Methods: A retrospective longitudinal study was conducted at the selected Critical Care Units of KNH. The study involved the extraction of data from medical records of patients aged 13 years and above admitted to the Critical Care Units for 12 months. Data were abstracted using a pre-designed standardized data collection tool. The study variables were the five commonest isolated micro-organisms and the susceptibility patterns of the bacteria to the commonly used antibiotics. The prescribing patterns of the various antibiotics were also assessed.

Results: This study included 309 patients. The median age was 37 years [IQR 13, 83] There were more males (n=158, 51.1%). The most commonly isolated microorganisms were *Klebsiella pneumonia*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(23.9 %), *Acinetobacter baumanii* (16.4%) and *Escherichia coli* (10.5%). 11(67%) *K. pneumonia* isolates were sensitive to meropenem. *A. baumanii* isolates (82%, n=9) were sensitive to amikacin, 55% (n=6) to meropenem, 27% (n=3) were sensitive to ceftazidime and cefepime. All the *A. baumanii* isolates were resistant to tigecycline, linezolid, and teicoplanin. Most of the *E. coli* isolated were sensitive to meropenem (86%, n=6), amikacin (71%, n=5) and 43% (n=3) to gentamycin. The antimicrobial agents commonly prescribed were Ceftriaxone (36.8%), Metronidazole (16.9%) and Meropenem (12.4%).

Conclusions: Klebsiella pneumonia, Acinetobacter baumanii, and Escherichia coli were the principal pathogens isolated. They showed susceptibility to meropenem and amikacin. Ceftriaxone was the most common antibiotic prescribed despite most isolates showing resistance. The study observed that the culture and sensitivity results seldom informed antibiotic prescribing

5015 | Influence of Dementia on Medication-related Quality of Care in Long-term Aged Care

Gillian E Caughey[1,2], Catherine Lang[1], Janet Sluggett[1], Steve Wesselingh[1] and Maria C Inacio[1]

[1]*South Australian Health and Medical Research Institute, Adelaide, Australia*; [2]*University of South Australia, Adelaide, Australia*

Background: Dementia is one of the biggest global challenges for health and social care and is highly prevalent in older people living in long-term aged care. People with dementia are particularly susceptible to medication-related adverse events and harms, and poor quality of life due to their physical and psychological frailty and presence of multimorbidity and polypharmacy. Clinical indicators of medication-related quality of care can be used to monitor, evaluate and improve medication use and resident outcomes.

Objectives: To examine the influence of dementia on medication-related quality of care in older people residing in long-term aged care.

Methods: A retrospective cohort study of all older people residing in long-term care facilities in Australia between 1 Jan and 31 Dec 2016 was conducted using national data from the Registry of Senior Australians (ROSA), a national cohort of over 2.8 million older Australians receiving aged care services and linked to multiple databases, including pharmacy claims. Medication-related quality of care indicators examined included antipsychotic use without a diagnosis of psychosis, high sedative load (score >=3), and chronic opioid use. Logistic regression was used to determine indicator prevalence rates and 95% CI, adjusted for age, sex and number of comorbid conditions and stratified by the presence of dementia.

Results: A total of 212,405 long-term residents, including 108,489 (51.1%) with dementia, in 2690 facilities throughout Australia were included in the study cohort. The median age was 84 years (IQR 79-89), 62% were female and the median number of comorbid conditions was 5 (IQR 3-7). Polypharmacy was common; 77.5% were dispensed > 5 medications with 47.4% receiving > 10 medications. The prevalence of antipsychotic use in residents with dementia was 31.7% (95% CI 31.5-32.0), and in residents without dementia 13.1% (95% CI 12.9-13.2). Little difference in the prevalence of high sedative load between those with dementia (45.3% 95% CI 45.0-48.0) and without dementia (50.8% 95% CI 50.5-51.2) or chronic opioid use (dementia 24.3% 95% CI 24.1-24.6 and no dementia 26.7% 95% CI 26.5-26.9) was observed.

Conclusions: Little differences in medication-related quality of care was observed between residents with and without dementia apart from the use of antipsychotics. However, given the high prevalence of utilisation of these medications, together with the potential for significant risk of harms, monitoring their use is important to facilitate the identification of those in need of medication review, to assess appropriateness, continued use or potentially deprescribe.

5016 | Prevalence of and factors associated with chronic opioid utilization among commercially insured us adults with co-morbid chronic pain and mental health disorders

Abisola Olopoenia and Linda Simoni-Wastila

University of Maryland, Baltimore, MD

Background: Little is known about factors associated with chronic use of opioids among youth and adults with co-morbid chronic non-cancer pain (CNCP) and mental health disorders (MHD)

Objectives: Our goal was to examine the prevalence of, and potential risk factors associated with, chronic use of prescription opioids among commercially insured youth and adults aged 14 through 64 with co-morbid CNCP and MHD

Methods: We conducted a retrospective cohort study utilizing the IQVIA™ Health Plan Claims Data from January 1, 2006 to December 31, 2015. CNCP was defined as any diagnosis of back, head, neck, arthritis, or chronic pain (index date). MHD was assessed in the 6-months prior to the index date and included mood disorders, anxiety, depression, personality disorders, adjustment disorders, and attention deficit disorders. Demographic and clinical factors included age, sex, non-chronic non-cancer pain (NCNCP), sedatives, muscle relaxants, number of chronic co-morbidities, antidepressants, and substance use disorders (SUD.) These factors were assessed in the 6-months prior to the index pain diagnosis. Based on days supplied (none, acute [<90 days] and chronic[≥90days]), we constructed a 3-categorical level dependent measure of opioid use. We estimated the prevalence of chronic opioid receipt among youths and adults with concurrent CNCP and MHD, and used multinomial logistic regression (AOR; 95 CI) to estimate the associations of these clinical and demographic factors with chronic opioid receipt

Results: Among 143,923 adults with CNCP and MHD, 32,621 (3.71%) and 10,592 (1.20%) had acute and chronic use of opioids, respectively. When compared to acute opioid use, chronic prescription opioid use was higher among middle-aged adults (46-64) and those with diagnoses of SUD, NCNCP, and ≥3 chronic co-morbidities (p<0.01) After adjusting for demographic and clinical factors, muscle relaxants (3.98;3.80-4.17), ≥3 chronic co-morbidities (3.14;2.89-3.41), opioid-

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

related SUD (2.99;2.67-3.36), non-opioid related SUD (1.94;1.73-2.18), neuropathic pain (1.75;1.64-1.86), and antidepressants (1.78;1.69-1.87) were the strongest predictors of chronic opioid use

Conclusions: A considerable proportion of individuals with co-morbid CNCP and MHD chronically utilize opioids. Within this population, individuals with diagnoses of substance use disorders, multiple co-morbidities, and those who use muscle relaxants are at even higher risk of chronic opioid use. This population is potentially highly susceptible to opioid-related adverse outcomes

5034 | Linaclotide utilization and potential for off-label use or misuse in three European countries

Javier Cid Ruzafa[1], Anna Schultze[2], Mai Duong[3], Yi Lu[3], Robert Donaldson[3], Darren Weissman[4] and Ahunna Ukah[5]
[1]*Evidera, Barcelona, Spain;* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom;* [3]*Evidera, London, United Kingdom;* [4]*Allergan, Madison, NJ;* [5]*Allergan, Irvine, CA*

Background: Linaclotide is used to treat moderate-to-severe irritable bowel syndrome (IBS) with constipation (IBS-C) in adults. Real-world treatment patterns of linaclotide use are largely unknown. Two subgroups with potential for off-label use are patients with obesity/eating disorders (ED), considered at risk of use for weight loss or as a laxative, and those with prior mechanical bowel obstruction (MBO) or inflammatory bowel disease (IBD).

Objectives: To describe real-world use of linaclotide in groups of patients with potential for off-label use.

Methods: This was a post-authorisation safety study requested by European health authorities, conducted in 3 databases: the UK Clinical Practice Research Datalink, the Information System for Research in Primary Care platform in Spain and the linked Patient, Prescription and Causes of Death Registries in Sweden. Patients prescribed linaclotide between its launch date (UK, Sweden 2013; Spain 2014) and end of 2017 were included. The date of the first linaclotide prescription or dispensation was index date. IBS was identified with diagnostic (Read codes in the UK and International Classification of Diseases 10th revision diagnostic codes in Spain and Sweden) and treatment codes using an algorithm. Obesity, ED, MBO and IBD were assessed through codes, body mass index, and medical history.

Results: There were 1,319, 1,981 and 5,081 linaclotide users from the UK, Spain and Sweden with a median age of 45, 57 and 51 years, respectively, mostly females. The most common concomitant medications were laxatives in the UK and Sweden (72%) and proton pump inhibitors in Spain (41%). In the UK, Spain and Sweden, respectively: 41%, 40% and 69% of linaclotide users did not have an IBS diagnosis and among IBS patients, 69%, 62% and 93% were classified as having IBS-C; 17%, 30% and 2% of users were considered at risk of use of linaclotide for weight loss or as a laxative because of obesity or ED and 0.6%, 2.5% and 1.2% of all users had a history of ED in the year prior to index date; 3.5%, 4.6% and 5.7% of linaclotide users had history of MBO in the year prior to index date or IBD at any time up to index date, with MBO accounting for 0.3%, 2.4%, and 1.1% of all users. The median time between the last MBO and the index date was 6 months.

Conclusions: Linaclotide use by patients with no code of IBS diagnosis was common. Potential linaclotide misuse was limited, as evidenced by the small subgroup sizes, except for those with a possible risk of use for weight loss or as laxative. Linaclotide prescription should occur in accordance with the approved label and use by patients in which its use is contraindicated should be avoided.

5059 | The Use of antibiotics without prescription and the emergence of multidrug-resistant bacteria

Jose J. Hernandez[1,2]
[1]*University of Puerto Rico School of Pharmacy, San Juan, PR;* [2]*Texas A&M College of Pharmacy, College Station, TX*

Background: The irrational use of antibiotics is primarily responsible for the global spread of antibiotic resistance. The use of antibiotics without prescription has been associated with shorter courses and suboptimal drug and dose choices. It has been estimated that more than 50% of the antibiotics worldwide are sold without a medical prescription even though dispensing without a prescription is illegal in most countries.

Objectives: 1) Determine the prevalence of obtaining antibiotics without a prescription in the Commonwealth of Puerto Rico; 2) Describe the patterns of dispensing antibiotics without a valid prescription; 3) Establish if the development of Community-Acquired Multidrug-Resistant (CA-MDR) infections requiring hospitalization is associated with the practice of obtaining antibiotics without a prescription, and describe the pattern of dispensing antibiotics without prescription in Puerto Rico.

Methods: This study followed a case-control study design. Patients hospitalized in a secondary hospital in the northern part of Puerto Rico between August 1, 2018, and April 30, 2019, were considered for potential inclusion. The case group consisted of hospitalized patients with CA-MDR infections as defined by the Magiorakos criteria. The control group consisted of hospitalized patients with community-acquired infections that were non-resistant. Infections occurring ≤ 2 days after the hospitalization were considered community-acquired infections, and those manifesting at a later point, were considered nosocomial infections.

Results: 126 patients were included in the study. Mean (SD) age 68.8 (±15.8) years and 66 (52%) were female. 72 (57%) met the criteria for CA-MDR infections and 48 (38%) reported obtaining antibiotics without prescription. Among those who obtained antibiotics without a prescription, 38 (79%) acquired them from a pharmacy, while 30 (63%) reported their reason for the illegal acquisition was poor accessibility to physicians. The multivariate analysis showed that patients who used antibiotics without prescription were 1.24 times more likely to had a CA-MDR infection than those who did not use

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

them [OR 1.24, CI = 0.60-2.58, p = 0.56]. Despite the apparent association, the result was not statistically significant.

Conclusions: This study provides an up-to-date estimate of CA-MDR infections in hospitalized patients that may have resulted from the use of antibiotics without a prescription in Puerto Rico. Also, the findings suggest that antibiotics are frequently supplied without prescription in Puerto Rico, even though this is an illegal practice.

5061 | Adherence to oral anticoagulant and antiplatelet therapies after an acute ischemic stroke or TIA in atrial fibrillation patients

Judit Riera-Arnau[1,2], Gabriel Sanfélix-Gimeno[3], Clara Liliana Rodriguez-Bernal[3], Daniel Bejarano-Quisoboni[3], Isabel Hurtado[3], Aníbal García-Sempere[3] and Salvador Peiró[3]

[1]Vall d'Hebron University Hospital, Barcelona, Spain; [2]Autonomous University of Barcelona, Bellaterra, Spain; [3]Foundation for the Promotion of Health and Biomedical Research of Valencia Region (FISABIO), Valencia, Spain

Background: Antiplatelet therapies (APT) are often given as antithrombotic treatment (ATT) for secondary prevention in atrial fibrillation (AF) although they should be only an alternative when oral anticoagulants (OAC) are contraindicated.

Objectives: To assess adherence to different ATT options after discharge for an acute ischemic stroke (AIS) or TIA in patients with AF.

Methods: This is a population-based retrospective study using electronic health records from the Valencia Region, Spain. We included all the patients diagnosed with AF that were prescribed an ATT after discharge for an AIS or TIA, from Jan 2010 to Dec 2015. We classified them as treated with OAC or APT alone, or OAC+APT, based on the prescriptions within the first month after the first one. We calculated the proportion of days covered (PDC) for a fixed time-window of 12 months after discharge. We used prescription and dispensation data, and thus we are actually estimating the adherence of the patients to the prescribed medications issued by physicians. We defined adherence as PDC>=80%. Discontinuation was also estimated for the 1st year after discharge using a permissible gap of 30 days.

Results: We included 8084 with AF and discharged after an AIS or TIA, of which 7,237 (89,5%) were prescribed an ATT. The 32,1% (n=2,323) of those treated received an APT, a 48,3% (n=3,496) an OAC, and a 19,6% (n=1,418) OAC+APT. The lag time to initiate ATT after discharge, took a mean of 15.6 days in the APT group, 15.7 in the OAC group and 15.2 in the OAC+APT group, all of them with a median of 4 days [IQR:0-17]. 96/2505 patients that in the first month were prescribed APT never filled a dispensation, compared with 82/3751 and 12/1244 in the OAC and OAC+APT groups. Patients in the APT, OAC and APT +OAC groups had a PDC during the first year after discharge of 87.6%, 93.8% and 92.9%, respectively. The percentage of adherent patients was 82.6%, 91.4% and 89.5%. The discontinuation rate at 1 year was significantly higher in the APT group (35.4%), as compared with OAC (27.4%) and OAC+APT (23.6%) groups.

Conclusions: In this study, patients with AF and AIS or TIA who started OAC or OAC+APT after discharge, showed a higher adherence than APT, despite among all of them it was high. The majority of patients had a PDC>80%. One third of the patients in the APT group discontinued the treatment within the first year, compared with a quarter in the others. Further research is needed to assess other factors related to this adherence results, and their clinical implications for this population.

5075 | Concurrent Use of Multiple Antipsychotics Plus Excessive Polypharmacy: Cross-sectional Study of a Vulnerable Population

Maíra R Alves, Rejane CF Mayer, Fabiane R Motter and Luciane C Lopes

University of Sorocaba, Sorocaba, Brazil

Background: The deinstitutionalized patients with mental illness using public Assisted Living Services (ALS) are a vulnerable population. The use of multiple concurrent antipsychotics plus excessive polypharmacy could bring serious adverse events and consequences for functional status of this vulnerable population.

Objectives: To examine the prevalence and the associated factors with concurrent use of multiple antipsychotic and excessive polypharmacy.

Methods: Cross-sectional study conducted with users with mental illness from 40 ALS of a city of São Paulo State, Brazil. We collected data from three sources of information: 1. Medical records; 2. Pharmacy records; 3. Interview with patients using validated tools. The information about drug utilization was crosschecked using the medical and pharmacy records. Sociodemographic data (sex and age) and functional were obtained using the interview with WHODAS tool. Clinical variables (diagnostic, comorbidities, time in hospital, timing of deinstitutionalization) were extracted from the medical records. Poisson regression was performed to identify factors associated with concurrent use of multiple antipsychotics plus excessive polypharmacy.

Results: Of 245 users interviewed, 132 individuals (53.8%, CI 39.8; 52,.4) were men, and the median age was 50.9 (SD±11.7) years. Overall, 63.1% (CI 95% 57.0%; 69.2%) of the participants had concurrent use of multiple antipsychotics and 23.4% (CI 18.1%; 28.7%) of the participants had excessive polypharmacy. Haloperidol (62.9%), Chlorpromazine (46.1%) and Risperidone (30.6%) were the most frequently prescribed. The functional status index found with the WHODAS tool was 10,4 (SD±7,6). After adjusted analysis, only excessive polypharmacy was associated with age < 60 years (PR= 2.93, CI 95%1.03; 8.34, p= 0.027) and time in hospital < 10 years (PR= 2.74, CI 95% 1.16; p= 0.021) and timing of deinstitutionalization < 4 years (PR= 2.54, CI 95%1.29; 5.01, p= 0.007).

Conclusions: We found high prevalence of concurrent use of multiple antipsychotics plus excessive polypharmacy. This represents that the prescription practices are failing the guidelines recommendations and that old prescription practices used before deinstitutionalization are still being held, what can be affecting the process

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of social rehabilitation and the functional status of this vulnerable population. The results suggest the need for interventions by health authorities.

5078 | The role of the patient-provider relationship in racial/ethnic disparities in nonadherence to antihypertensive medications

Macarius Donneyong[1], Teng-Jen Chang[1], Autumn Carey[2] and John Bridges[3]

[1]Ohio State University, Columbus, OH; [2]Ohio State University, Columbus, OH; [3]Ohio State University, Columbus, OH

Background: Nonadherence (NA) to antihypertensive medications (AHM) treatment is higher among Blacks compared to non-Hispanic Whites (NHW).

Objectives: To quantify race/ethnic disparities in AHM NA and to assess whether constructs of patient-provider relationships (PPRs) modify this association.

Methods: AHM users were identified from the Medical Expenditure Panel Survey (MEPS) data, 2010-2017. MEPS is a national panel survey on health care expenditures, verified self-reported prescribed medication use, several self-reported healthcare access measures, etc. Three domains of PPRs (communication, trust and shared-decision making) were defined from participant responses to surveys about their experiences with healthcare services received. Measures of annual medication refill adherence (MRA) were calculated separately for each therapeutic class (TC) as the total days' supply divided by 365 days. Overall MRA was obtained as the average of MRAs for participants was using more than one AHM. Patients were considered to be nonadherent if their overall MRA was <80%. Data collected in year 1 was used to define patient-provider factors and all covariates; year's 2 data used to define AHM NA. Multivariable-adjusted Generalized Linear Models (GLM), weighted by survey weights, were used to measure the odds ratios (ORs) between race/ethnicity and AHM NA. Separate GLMs were also used to assess the associations between each PPR construct and AHM NA, adjusted for by patient demographics and provider's race/ethnicity, gender, specialty and location. Relative excess risk due to interactions (RERIs) between race/ethnicity (each minority group vs. NHW) and each binary construct of PPR were calculated to test for potential effect modification.

Results: The results reported are based on a weighted sample of 17,796,539 (50% NHW; 25% Blacks; 18% Hispanics; and 7% Others) participants. Compared to NHW, AHM NA was higher among Blacks (OR=1.44, 95%CI: 1.28, 1.63), Hispanics (OR=1.30, 95%CI:1.10, 1.52) and others (OR=1.30, 95%CI:1.09, 1.55) in multivariable-adjusted models. Patient involvement in shared decision making was significantly associated with lower risk of AHM NA in unadjusted but not in multivariable-adjusted models; other PPR constructs were not significant in both models. Positive additive interactions were observed between race/ethnicity and high trust and shared decision making.

Conclusions: NA to AHM was significantly higher among racial/ethnic minorities, compared to NHW. This relationship was modified by trust and patient involvement in shared decision making.

5096 | Prevalence of exposure to high-priority drug-drug interactions among community-dwelling non-elderly adults in Quebec, Canada

Araceli Gonzalez Reyes[1], Pierre Pluye[2], Denis Roy[3] and Tibor Schuster[1]

[1]McGill University, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada; [3]Institut National d'Excellence en Santé et en Services Sociaux, Montreal, QC, Canada

Background: Drug-drug interactions (DDI) are a recognized risk for specific patient populations, such as hospitalized patients and those living with a condition requiring complex pharmacotherapy; their prevalence among the general population of non-elderly community-dwelling adults is unknown.

Objectives: 1) To measure the prevalence of exposure to high-priority DDI among community-dwelling adults in Quebec; 2) To identify the demographic and health system variables that may help predict the risk of exposure to high-priority DDI.

Methods: We conducted a retrospective cohort study using provincial medical administrative databases on a random sample of 5% of all community-dwelling adults aged 18-64 years on April 1, 2015 with continuous coverage by the public drug insurance between April 1, 2014 and March 31, 2017. Drug reimbursement claims were used to identify periods of temporally overlapping exposure to ≥2 active ingredients (AI) between April 1, 2015 and March 31, 2016. DDI were identified within periods of temporally overlapping exposure to ≥2 drugs using the list of high-priority DDI developed by the U.S. Office of the National Coordinator for health information, in combination with the AZCERT lists of clinically important DDI and QT-prolonging drugs. Incident DDI cases were identified as having no prior exposure to any high-priority DDI in the 12 months preceding the study. Demographic characteristics, health service use, continuity of care, and index of multimorbidity were evaluated as predictors of exposure to DDI; analyses are ongoing.

Results: Our cohort included 63,834 individuals aged 18-64 (mean age 44.9 [95% CI: 44.8-45], 51.6% female); among these, 41,380 (65.3%) claimed ≥1 active ingredient (AI) during the study year, and 34,553 (54.1%) claimed ≥2 AI during the study year. A total of 33,273 individuals (52.1% of full cohort, 96.3% of those with≥2 AI) had ≥1 day of overlapping exposure to ≥2 drugs. A total of 7,498 individuals were exposed to ≥1 DDI over 12 months (11.7% of full cohort, 22.5% of those with ≥1 day of overlapping exposure to ≥2 drugs); exposed individuals had a median of 1 DDI (IQR 2, range 1-28). The DDI with highest prevalence involved QT-prolonging drugs (19 of the 26 most prevalent DDI). Atypical antipsychotics and SSRI antidepressants were involved in 14 of the 26 most prevalent DDI among this population.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Exposure to high-priority DDI is common among community-dwelling non-elderly adults in Quebec. The clinical consequences of this exposure are unknown.

5132 | Factors Driving Self-medication with Antimicrobials in Karaikal, India

Devashree Moktan[1] and Syed Ilyas Shehnaz[2]
[1]*Jawaharlal institute of postgraduate medical education & research (JIPMER), India, Pondicherry, India;* [2]*Saveetha Medical College and Hospital, Chennai, India*

Background: The habitual use of antimicrobials is linked to the rise of bacterial resistance, narrowing the effective range of the available drugs. A leading cause of bacterial resistance is the overall volume of antimicrobial consumption, especially the self-medication with antimicrobials (SMA). Inquiring the general public directly and recognizing the reasons and rationale of individuals for SMA enables formation of effectual strategies tackling the key predictors. However to the best of our knowledge no studies have been done in Karaikal to find out the extent of this problem.

Objectives: To determine the factors driving individuals to self-medicate with antimicrobials and to ascertain the prevalence and practice of consumption of non-prescribed antimicrobials in Karaikal, Puducherry, India.

Methods: Our hospital based cross-sectional study was conducted between June 2018 and September 2018 in the various Out-Patient Departments (OPD) of the Government General Hospital of Karaikal, India. After Institutional Ethics Committee clearance was obtained, a structured validated questionnaire was used to collect data from 504 patients and their relatives. Data analysis was done using SPSS version 25. Descriptive statistics were used and Pearson's Chi-square test was used to determine the associations between different variables. Variables found significantly associated with SMA ($p<0.05$) in the bivariate analysis were included in the multiple logistic regression model and the odds ratio (OR) and corresponding 95% confidence intervals were generated.

Results: One-third of the participants (33.9%) reported SMA in the past six months with the prevalence significantly affected by male gender(adjusted OR=1.83; 95% C.I.:1.2-2.79), a preference for SMA during minor illnesses (adjusted OR=3.05; 95%C.I.:1.77-5.25)and a history of SMA among family members(adjusted OR=3.43; 95%C.I.:2.16-5.43). The most commonly self-prescribed drug was Amoxicillin (55.2%) and the antimicrobials were mostly obtained from pharmacies (91.8%). Self-prescribed antimicrobials were commonly used to treat cold, cough and fever. Our participants self-medicated with antimicrobials because they found it easier to do so (32.2%) and as it saved them time (35.7%) and money (32.2%).

Conclusions: Our study revealed that the prevalence of SMA was high in Karaikal, Puducherry, India The high prevalence of self-prescribed antimicrobials can be lowered by approaching societal-cultural practices through community education, the supply-demand chain through stricter regulations of pharmacies and enforcing health policies for rational use of antimicrobials.

5133 | Are patients less likely to adhere to antidepressant treatment if they are not satisfied with their provider?

Macarius Donneyong[1], Teng-Jen Chang[1], John Bridges[2] and Olivia Okereke[3]
[1]*Ohio State University, Columbus, OH;* [2]*Ohio State University, Columbus, OH;* [3]*Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: There is inadequate data on how patient satisfaction with their provider might impact racial/ethnic disparities in non-adherence (NA) to antidepressant (AD).

Objectives: To quantify racial/ethnic disparities in AD nonadherence and to assess whether disparities in patient satisfaction with their provider modifies the race/ethnicity-AD NA relationship.

Methods: AD users were identified from the Medical Expenditure Panel Survey (MEPS) data, 2010-2017. MEPS is a national panel survey on health care expenditures, verified self-reported prescribed medication use, access to and satisfaction with provider, etc. Satisfaction with provider was defined from patient responses to five major questions including whether the provider asks about medications and other treatments received elsewhere. Measures of annual medication refill adherence (MRA) were calculated separately for each therapeutic class (TC) as the total days' supply divided by 365 days. Overall MRA was obtained as the average of MRAs for participants using more than one AD. Patients were considered to be nonadherent if their overall MRA was <80%. Data collected in year 1 was used to define satisfaction levels and all covariates; year's 2 data was used to define AD NA. Multivariable-adjusted Generalized Linear Models (GLM), weighted by survey weights, were used to measure the odds ratios (ORs) between race/ethnicity and AD NA. Separate GLMs were also used to assess the associations between satisfaction levels (high, medium, low) and AD NA, adjusted for by patient demographics and provider's race/ethnicity, gender and specialty. Statistical interaction and stratified analysis were performed to assess for effect modification.

Results: Of the 58,021,381 weighted sample of AD users, majority (84%) were non-Hispanic Whites (NHW) compared to 6% Blacks; 7% Hispanics; and 3% Others. Compared to NHW, AD NA was significantly higher among Blacks (OR=1.51, 95%CI: 1.20, 1.89), Hispanics (OR=1.63, 95%CI:1.30, 2.04) and others (OR=1.15, 95%CI:0.81, 1.63) in multivariable-adjusted models. High satisfaction with provider, compared to low, was significantly associated with lower risk of AD NA (OR=0.63, 95%CI:0.48, 0.83) in multivariable-adjusted models. Racial/ethnic minorities were less satisfied with their providers compared to NHW ($P<0.05$); this further exaggerated the magnitudes of racial/ethnic disparities.

Conclusions: Racial/ethnic minorities were less satisfied with their providers and more likely to be nonadherent to AD. Disparities in satisfaction with providers further expanded racial/ethnic disparities in AD NA.

5146 | Utilization of Antihypertensive Medication in Ghana

Macarius Donneyong[1], Teng-Jen Chang[1], Anton Pottegård[2] and Jesper Hallas[2]

[1]*Ohio State University, Columbus, OH;*[2]*University of Southern Denmark, Odense, Denmark*

Background: Hypertension is now the second leading cause of outpatient morbidity in Ghana. However, there is little data on the access to and quality of antihypertensive medication (AHM) treatment in Ghana.

Objectives: To identify the predictors of use and quality of AHM treatment.

Methods: We analyzed the 205 Ghana National Health Insurance Scheme (NHIS) electronic claims data. Hypertension diagnosis was defined using the ICD-10 codes. We restricted our analysis to patients aged 12 years or older. Three AHM use and quality of treatment outcomes were measured: 1) prevalence of AHM use; 2) clinical guideline-concordant AHM use; and 3) the daily defined dose of AHM used. Patient-related (age, sex, comorbidities, use of other medications) and provider-related (region of healthcare provider, specialty type of healthcare provider) factors. Logistic regression models were used to model all outcomes except dose of antihypertensive treatment which was a continuous variable. A separate multiple linear regression model was used to identify potential predictors of dose (DDD) of antihypertensive medications dispensed per patient.

Results: Of the 11,215 hypertension patients identified, 92.6% of them were using at least one AHM agent. AHM used was associated with older age, female sex, outpatient hospital visits, use of other cardiovascular and antidiabetic agents. However, those with comorbid diabetes (OR=0.49, 95%CI:0.35, 0.68) and peripheral artery disease (PAD) (OR=0.16, 95%CI:0.05, 0.55) were less likely to use AHM. Only nearly a third (36.6%) of patients were treated according to clinical guidelines; the major predictors of which included older age, comorbid diabetes (OR=4.21, 95%CI:2.90, 6.10) and renal disease (OR=36.5; 95%CI:28.28, 47.15). All but male sex, metformin use, anticoagulant use and PAD were associated with increasing AHM DDDs.

Conclusions: Although AHM use was nearly impressive, only a about a third of hypertension patients were treated according to clinical guidelines. Several patient demographic, comorbidity and medication use factors were significant predictors of AHM access and quality of treatment.

Drug Utilization Research -> Trends and comparisons

49 | Characteristics of New Users of Newer Antidiabetic Drugs in Canada and the United Kingdom

Vanessa C Brunetti[1,2], Audray St-Jean[2], Sophie Dell'Aniello[2], Anat Fisher[3], Oriana HY Yu[2,4], Shawn C Budgen[5,6], Jean-Marc Daigle[7], Nianping Hu[8], Silvia Alessi-Severini[5,9], Baiju R Shah[10,11], Paul E. Ronksley[12], Lisa M. Lix[13], Pierre Ernst[2,14], Kristian B Filion[1,2,14] and the CNODES Investigators[15]

[1]*McGill University, Montreal, QC, Canada*[2]*Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada*[3]*University of British Columbia, Vancouver, BC, Canada*[4]*Jewish General Hospital, Montreal, QC, Canada*[5]*University of Manitoba, Winnipeg, MB, Canada*[6]*Memorial University of Newfoundland, St John's, NL, Canada*[7]*Institut National d'Excellence en Santé et en Services Sociaux (INESSS), Quebec, QC, Canada*[8]*The Health Quality Council, Saskatoon, SK, Canada*[9]*University of Manitoba, Winnipeg, MB, Canada*[10]*Institute for Clinical Evaluative Sciences (I.C.E.S.), Toronto, ON, Canada*[11]*Sunnybrook Health Sciences Centre, Toronto, ON, Canada*[12]*University of Calgary, Calgary, AB, Canada*[13]*University of Manitoba, Winnipeg, AB, Canada*[14]*McGill University, Montreal, QC, Canada*[15]*Canadian Network for Observational Drug Effect Studies (CNODES) Investigators, Montreal, QC, Canada*

Background: The characteristics of patients using newer antidiabetic drugs (sodium-glucose co-transporter 2 inhibitors [SGLT-2i], dipeptidyl peptidase 4 inhibitors [DPP-4i], and glucagon-like peptide 1 [GLP-1] receptor agonists) in a real-world setting are poorly understood.

Objectives: To describe the characteristics of new users of SGLT-2i, DPP-4i, and GLP-1 receptor agonists in Canada and the United Kingdom (UK).

Methods: The Canadian Network for Observational Drug Effect Studies (CNODES) conducted a multi-center cohort study using administrative health databases from 7 Canadian provinces and the UK Clinical Practice Research Datalink. We assembled a base cohort of new users of antidiabetic drugs between 2006 and 2018. From this base cohort, we constructed 3 separate cohorts of new users of SGLT-2i, DPP-4i, or GLP-1 receptor agonists between 2016 and 2018. Descriptive statistics were used to characterize the cohorts.

Results: Our base cohort of 2,175,815 new users of antidiabetic drugs included 166,722, 194,070 and 27,719 new users of SGLT-2i, DPP-4i and GLP-1 receptor agonists respectively, across jurisdictions. New users of GLP-1 receptor agonists were more likely to be female (54%) than new users of SGLT-2i (41%) or DPP-4i (44%), while new users of DPP-4i were more likely to be older (mean ± SD: 67.8 ± 12.3 yrs) than new users of SGLT-2i (64.4 ± 11.1 yrs) and GLP-1 receptor agonists (56.7 ± 12.2 yrs). The prevalence of cerebrovascular disease (SGLT-2i: 4%, DPP-4i: 7%, GLP-1 receptor agonists: 2%) and coronary artery disease (SGLT-2i: 20%, DPP-4i: 22%, GLP-1 receptor agonists: 16%) was similar among groups. In the UK, prevalence of obesity (body mass index ≥30kg/m^2; SGLT-2i: 71%, DPP-4i: 52%, GLP-1i: 88%) and impaired renal function (estimated glomerular filtration rate <60 mL/min/1.73m^2; SGLT-2i: 6%, DPP-4i: 25%, GLP-1 receptor agonists: 15%) differed greatly between groups. New use of SGLT-2i or GLP-1 receptor agonists, but not DPP-4i, was commonly preceded by insulin use in Canada (SGLT-2i: 26%, GLP-1 receptor agonists: 33%) and the UK (SGLT-2i: 17%, GLP-1 receptor agonists: 29%).

Conclusions: Although all 3 classes are recommended as 2nd or 3rd line therapy, important differences in patient characteristics of new users of newer antidiabetic drugs exist. GLP-1 receptor agonists appear to have been prescribed off-label for weight loss, and SGLT-2i are less frequently used among patients with renal insufficiency. Although large trials have demonstrated benefits with SGLT2i and GLP-1 receptor agonists, these drugs do not appear to be preferentially prescribed to patients at elevated cardiovascular risk.

113 | Spatial Distribution of Deprivation Driven Inequalities in Opioid Prescribing in English Primary Care: A Cross-sectional Analysis

Magdalena Nowakowska, Salwa Zghebi, Rosa Parisi, Li-Chia Chen, Darren M Ashcroft and Evangelos Kontopantelis
University of Manchester, Manchester, United Kingdom

Background: In 2018/19, over 23 million opioid prescriptions were issued in English primary care. Levels of prescribing are not distributed equally across regions and populations. A greater understanding of the geographical differences and social drivers of opioid prescribing is needed to guide policy responses and interventions.

Objectives: To explore regional variations in opioid prescribing in England and the role of socio-economic deprivation in driving inequalities in opioid prescribing.

Methods: National cross-sectional study of opioid prescriptions in year 2018/2019 in England. Using national general practice prescription data, the total volume of opioids prescribed in a practice was calculated and translated into Defined Daily Doses (DDD). The prescription data was attributed to 32,844 Lower Layer Super Output Areas (LSOAs), geographical units with an average of 1,500 people. Linear regression was used to model the association of socio-economic deprivation, measured using the Index of Multiple Deprivation (IMD) 2019 data, with levels of prescribing. The model accounted for population demographics and prevalence of selected health conditions. To examine the deprivation driven inequalities in opioid prescribing, we estimated the predicted average value of prescribing at each IMD level and compared prescribing in most and least deprived areas in each Clinical Commissioning Group (CCG).

Results: In total, 5,350,151,699 DDDs of opioids were prescribed. Prescribing of opioids, measured by DDD/1000 populations/day, was not distributed randomly between LSOAs across England and varied between 4 to 1,905 DDD/1000 population/day. On average, 93.77 (SD: 1.90, p-value < 0.001) more DDD/1000 population/day were prescribed in the most deprived areas compared to the least deprived areas. There were 10 CCGs where average prescribing in the most deprived areas was over 100% higher than in the least deprived areas. CCGs with on average higher levels of prescribing and higher average levels of deprivation also had higher levels within prescribing variation.

Conclusions: Even after adjusting for differences in population structure, practices differ significantly across the country in opioid prescribing. Socio-economic deprivation is a significant predictor of prescribing. The difference between prescribing in most and least deprived areas was more substantial in some CCGs compared to others. Future policies and interventions should focus on areas with elevated levels of prescribing and tackling the deprivation driven inequalities in areas where they are most prevalent.

130 | Temporal trends and changes in indication for opioid use in Catalonia, 2007-2017: A population-based study of 6 million individuals

Junqing Xie[1], Aleksandra Turkiewicz[2], Gary Collins[1], Martin Englund[2], Victoria Y. Strauss[1] and D. Prieto-Alhambra[1]
[1]*University of Oxford, Oxfordshire, United Kingdom;* [2]*Lund University, Lund, Sweden*

Background: North America is currently suffering from an opioid epidemic, and recent data suggesting an increase in opioid use is also seen in northern and central Europe, but little data have been reported for the situation in southern Europe.

Objectives: To evaluate secular trends of opioid and their subtypes use in primary care and changes in indication associated with opioid initiation from 2007 to 2017 in Catalonia, Spain.

Methods: Data were obtained from the SIDIAP (The System for the Development of Research in Primary Care) database, which contains electronic medical records and dispensation data for ~ 6 million people (>80% of the Catalan population). The incidence proportion of opioid use (codeine, tramadol, fentanyl, and morphine, with the latter three classified as strong opioids) in each calendar year was calculated. The denominators were registered individuals meeting following criteria at the first day of each calendar year: 1) ≥18 years old, 2) ≥1 year of valid data, 3) no registered use of the same opioid in previous one year. The numerators were all new opioid users during each calendar year. Age-sex standardization was performed using the population at the year of 2007 as the reference. Indications were obtained based on the related diagnosis closet prior to therapy initiation from a prespecified list including musculoskeletal pains, bone fracture/s, post-surgery, and cancer.

Results: Between 2007 and 2017, the incidence proportion of total opioid use decreased firstly and then increased, with the lowest rate in 2013 (2.0%) and the highest rate in 2017 (3.3%). Specifically, the use codeine followed a similar trend with total opioid, but tramadol, fentanyl and morphine increased continuously from 0.61% to 1.71%, 0.03% to 0.12%, and 0.01% to 0.05% respectively. In the same period, musculoskeletal pains (back pain, neck/shoulder pain, and osteoarthritis pain) consistently dominated the indications for total opioid, codeine, tramadol treatment, with an attributable 90% of total use over years. But the proportion of strong opioid/s use related to musculoskeletal pain increased from 75% to 80% for fentanyl and 40% to 72% for morphine, which is companied by cancer-related opioid use decreasing from 17% to 8% and 55% to 13% respectively.

Conclusions: Use of strong opioids in primary care has increased substantially during the study period (2007-2017) in Catalonia, replacing the use of weaker opioids (codeine). Musculoskeletal pain has gradually become the most common indication for strong opioid prescriptions, which is an unexpected sign of chronic pain management.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 133 | Prescription drug use in testicular cancer patients: A Danish nationwide registry study

Anne Katrine Duun-Henriksen[1], Michael Kreiberg[2], Jakob Lauritsen[2], Mikkel Bandak[2], Thomas Wagner[2], Josephine Rosenvilde[2], Irene Petersen[3], Klaus K. Andersen[1], Christian Dehlendorff[1] and Gedske Daugaard[2]

[1]*Danish Cancer Society Research Centre, Copenhagen, Denmark;* [2]*Rigshospitalet, Copenhagen, Denmark;* [3]*University College London, London, United Kingdom*

Background: In developed countries testicular cancer is the most common solid tumour in men between 14 and 44 years of age. Testicular cancer is a highly curable disease with a 5-year survival rate around 95%, which gives rise to a growing population of long-term survivors.

Objectives: To describe the use of prescription drugs in testicular cancer survivors compared to a cohort matched on age.

Methods: From the Danish nationwide registries, we identified males diagnosed with incident testicular cancer during 2000-2015 and a randomly selected male comparison cohort matched on age at date of diagnosis. Eligible comparisons had to be cancer free and alive on the date of diagnosis (index date). Prescription history was obtained from the Danish National Prescription Registry. The men were followed from time of diagnosis/index date until date of death, date of second (testicular cancer patients)/incident cancer (comparisons) or end of study (31.12.2016) whichever occurred first. Drug use was assessed for 0-5, 5-10 and 10-15 years post diagnosis by estimating prescription rates with 95% confidence intervals (CI) for each time interval.

Results: In total, 5,043 patients and 22,197 individuals in a comparison cohort were included in the study with a mean age at time of diagnosis/index date of 38 years. Median follow up from diagnosis was 8.8 years (interquartile range: 4.9-13.6 years). Testicular cancer patients had a higher prescription rate in all three intervals compared to the comparison cohort. Within the first 5 years after diagnosis/index date the rates among cancer patients and comparisons were 5.80 (95% CI: 5.76-5.83) prescriptions/person-year and 4.81 (95% CI: 4.80-4.83) prescriptions/person-year, respectively. Further, 5-10 years after diagnosis/index date, the rate among cancer patients and comparisons were 6.99 (95% CI: 6.95-7.03) prescriptions/person-year and 6.00 (95% CI: 5.99-6.02) prescriptions/person-year. The rates among cancer patients and comparisons 10-15 years after diagnosis/index date were 8.23 (95% CI: 8.16-8.29) prescriptions/person-year and 7.11 (95% CI: 7.09-7.14) prescriptions/person-year, respectively. We will assess and present which drug classes that contributed to this elevated prescription rate in testicular cancer survivors.

Conclusions: We confirmed a larger prescription drug burden in testicular cancer survivors during the first 15 years after diagnosis compared to a comparison cohort.

2354 | Over - the - counter drugs: A pharmacoepidemiological study in Greece

Georgios Poulentzas[1], Panagiotis Nikolaos Lalagkas[1], Theodora Tatsiou[1], Eleftherios Berberoglou[2], Dimitra Hadjipavlou - Litina[1], Christos Kontogiorgis[2] and Theodoros Constantinides[2]

[1]*Aristotle University of Thessaloniki, Thessaloniki, Greece;* [2]*Democritus University of Thrace, Alexandroupolis, Greece*

Background: Some medicines are available over the counter (OTC) in Greece without a prescription from physicians. There is a limited understanding of patients' knowledge level regarding OTC medicines, how they get informed about their proper use and whether there are any associated potential health issues.

Objectives: The goal of this study is to determine the knowledge level, habits, sources of information and selection criteria of Greek residents regarding OTC medicines, as well as their opinion about the dispensing of these medicines in non-pharmacy settings.

Methods: During 5 months of 2017, 920 people aged over 17, who were approached in community pharmacies and gathering points, were interviewed anonymously. 782 of those individuals participated (85% response rate) by answering a predesigned, cross-sectional questionnaire consisting of 12 multiple choice questions. Statistical analysis was performed with IBM SPSS Statistics v.15.0 program using descriptive statistics and chi-square while crude odds ratios were calculated with logistic regression.

Results: 507 respondents (64.8%) exhibited good knowledge about which medicines are categorized as OTC and which are not. Healthcare professionals (such as pharmacists and physicians) are the main source of information about the proper use, dosage and adverse effects of OTC medications for 648 (84%) of the respondents. When asked about the selection criteria regarding the purchase of OTC medication, physicians play the most critical role for 510 respondents (65.6%), followed by pharmacists for 468 (60.2%) and friends and family for 173 (22.3%). Product price is a more important factor for the selection of OTC medicines when it comes to elderly people (OR 1.73, 95% CI 1.10-2.72) Furthermore, 61.2% of the respondents stated that they are reluctant to buy OTC medicines from a non-pharmacy setting, while 69.6% believes that retail of OTC medicines in super markets will increase their abuse and misuse. However, younger people seem to be more positive about purchasing them elsewhere than pharmacies than older people (OR 2.20, 95% CI 1.37-3.54).

Conclusions: Healthcare professionals play a crucial role in people's information about OTC use and they have the biggest impact in the final selection. Finally, Greek society presents reluctance to accept OTC disposal elsewhere than community pharmacies.

2415 | Decreasing adherence to antiretroviral therapy over 4 years of follow-up in a commercially-insured US population of patients with HIV

Julie Priest[1], Rachel Bhak[2], Maral DerSarkissian[2], Cindy Garris[1], Alan Oglesby[1], Colin Kunzweiler[2], Ellie Fuqua[2], Suna Park[2] and Mei S Duh[2]

[1]*ViiV Healthcare, Durham, NC;* [2]*Analysis Group, Boston, MA*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Research has shown single-tablet regimens (STRs) of antiretrovirals (ARVs) lead to better medication adherence and viral suppression than multi-tablet regimens (MTRs); however literature in the commercially-insured US population is limited.

Objectives: This study compared yearly and longer-term ARV adherence among HIV patients overall and by STRs vs. MTRs.

Methods: A retrospective study using Optum Clinformatics US-based commercial claims data was conducted. Patients with an HIV-1 diagnosis during 2011-2017, age ≥ 18 years at index (date of first complete ARV regimen during the study period), and continuous enrollment for ≥ 3 months before index (baseline) and ≥ 12 months after index (observation) were included. MTRs were required to be comprised of 3 or more agents across at least 2 classes. Adherence was measured as the proportion of days covered (PDC) and compared using a Chi-square test. PDC was examined in the 1-year observation period for the overall analysis, and each year following index among patients with at least 4 years of continuous data. A subgroup analysis was conducted among patients with index during 2014-2016 to evaluate modern ARV adherence.

Results: Among the 15,153 included patients, median age was 45 years, the majority were male (88%), and 53% were in the Southern region of the US. At index, 58% (n = 8,715) were receiving an STR and 43% (n = 6,438) an MTR. During year 1, the proportion of patients with PDC ≥ 0.90 was 63% overall, and greater for STR than MTR (67% vs. 58%, $P < .001$). Among patients with at least 4 years of observation (STR: n = 1,961, MTR: n = 1,857), PDC ≥ 0.90 decreased over time, from 67% in year 1 to 53% in year 4, and was consistently significantly higher for STR than MTR ($P < .001$). In the subgroup of patients with index during 2014-2016 (STR: n = 3,646, MTR: n = 1,668), similar but slightly worse trends were observed, with PDC ≥ 0.90 for 57% of patients overall (STR: 62% vs. MTR: 48%, $P < .001$). Among patients with at least 3 years of observation (STR: n = 489, MTR: n = 322), PDC ≥ 0.90 also decreased over time (59% in year 1 to 42% in year 3), and was consistently significantly higher for STR than MTR ($P < .001$).

Conclusions: Adherence in this population of patients with HIV showed room for improvement in the first year of observation overall and in the modern ARV era, with those receiving STRs having higher adherence compared to those receiving MTRs. For the patients with 4 years of follow-up, adherence tended to decrease year on year. Maintaining high rates of ARV adherence is a critically important aspect of therapy for patients with HIV.

2427 | Frequency of opioid dispensing after surgical abortion in the United States

Liza R Gibbs[1], Julia A Pisc[1], Kari P Braaten[2], Brian T Bateman[3] and Elizabeth M Garry[1]

[1]*Aetion, Inc, Boston, MA;* [2]*Brigham and Women's Hospital, Boston, MA;* [3]*Brigham and Women's Hospital, Boston, MA*

Background: Over 800,000 induced abortions occur annually in the US, of which two thirds are surgical. NSAIDs, not opioids, are recommended for pain management after surgical abortion.

Objectives: Characterization of opioid dispensing among US commercially insured women after surgical abortion.

Methods: Women aged 15-50 years with an outpatient claim for dilation and curettage or evacuation surgical abortion (D&C/D&E) were identified in the IBM MarketScan database from Jan 2015 - Sep 2018, excluding those with >1 opioid fill in the prior 90d, evidence of opioid dependence or abuse in the prior 180d (baseline), or spontaneous abortion or mifespristone use in the 7d prior. The frequency of an oral opioid dispensing within 7d after abortion, refill in 6w after initial fill, chronic use (≥6 fills) in 1y after abortion or initial fill, and median morphine milligram equivalent (MME) total dose of the initial fill and refill were described. Multivariable logistic regression was used to evaluate predictors of opioid fill.

Results: Among the 28,304 women who underwent induced surgical abortion, 41.0% had D&E, 35.5% had anesthesia (not inclusive of moderate sedation), 9.4% had moderate sedation, and 8.3% had an opioid fill within 7d. The strongest predictors of an opioid fill were non-Northeast region [aOR (95% CI) West: 8.25 (7.23-9.42); South: 7.74 (6.75-8.87); Midwest: 5.12 (4.37-5.98)], moderate sedation for the procedure [1.57 (1.36-1.80)], and baseline depression or antidepressant use [1.41 (1.24-1.61)]. The median (IQR) MME dose was 75 (50-113), similar for D&C and D&E, and increased for women with an abortion complication [90 (75-150)] and from the Northeast [90.0 (54.0-150.0)] and South [90.0 (54.0-120.0)]. Of those with an opioid fill and 6w follow-up (N=2,257), 10.0% had a refill. Complication was the strongest predictor of refill [2.98 (1.59-5.59)]. Refill dose was 112.5 (75.0-225.0), increased relative to dose of the initial fill. Among women with 1y follow-up, chronic use was identified among 2.2% of women with an initial fill (N=1,396), versus 0.3% among those without (N=13,942). All analyses were conducted using the Aetion Evidence Platform v3.19.

Conclusions: The frequency of an opioid fill after surgical abortion among commercially insured women was high given recommendations that NSAIDs be used for clinical analgesia. Opioid prescribing contrary to recommendations may increase the potential for misuse or abuse.

2450 | Prescription patterns of outpatients and the potential of multiplexed pharmacogenomic testing

Sze Ling Chan[1], Hariz ZW Liew[1], Francis Nguyen[1], Julian Thumboo[2], Wan Cheng Chow[3] and Cynthia Sung[4]

[1]*SingHealth, Singapore, Singapore;* [2]*Singapore General Hospital, Singapore, Singapore;* [3]*Singapore General Hospital, Singapore, Singapore;* [4]*Duke-NUS Medical School, Singapore, Singapore*

Background: Pre-emptive pharmacogenomic (PGx) testing is potentially an efficient approach to improve safety and efficacy of drug treatment. However, it is unclear who and when to test in initial implementation efforts.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: The aim of this study was to describe the prescription pattern of PGx drugs among medical outpatients at a large tertiary-care hospital in Singapore to ascertain the potential of multiplexed PGx testing.

Methods: This is a retrospective cohort study of adult medical outpatients. The 5-year cumulative incidence (CI) for receiving new PGx drugs was estimated from dispensing records using competing risks analysis. We considered 3 groups of drugs in our analysis: (i) all PGx drugs (defined as Clinical Pharmacogenetics Implementation Consortium (CPIC) level A or B), (ii) PGx drugs with a CPIC or Dutch Pharmacogenetics Working Group (DPWG) guideline and (iii) PGx drugs with a clinical effect of class D-F based on DPWG guidelines (termed 'high risk' drug). Comparisons of CIs were also done by demographic and clinical characteristics using Gray's test.

Results: The 5-year CIs of receiving any new PGx drug, PGx drug with guidelines, and a 'high risk' drug were 42.6%, 37.3% and 13.7%, respectively. The most common newly prescribed PGx drugs were omeprazole, codeine, simvastatin, dextromethorphan and clopidogrel (5-year CIs: 17.4%, 8.8%, 8.1%, 4.9% and 3.7%, respectively). The 5-year CI of receiving at least 1 PGx drug was higher for patients >40 years old at index visit (43.6% vs. ≤40 years old 36.0%, $p < 2.2 \times 10^{-22}$), Malays and Indians (50.3% and 49.8% vs. Chinese 31.1%, $p < 2.2 \times 10^{-22}$) and those who attended one of the following 4 specialties at the index visit compared to other specialties: infectious diseases (46.2% vs. 42.6%, $p = 2.9 \times 10^{-4}$), psychiatry (48.3% vs. 42.3%, $p = 7.4 \times 10^{-13}$), renal (49.8% vs. 40.9%, $p < 2.2 \times 10^{-22}$) and rheumatology & immunology (54.8% vs. 41.7%, $p < 2.2 \times 10^{-22}$). Patients prescribed ≥5 drugs at index visit had a 5-year CI of 51.7% compared to those prescribed 0-4 drugs (41.7%, $p < 2.2 \times 10^{-22}$).

Conclusions: Medical outpatients have a substantial probability of benefiting from pre-emptive PGx testing. Certain subgroups of patients have higher probability of receiving PGx drugs, but predictive modelling may be needed for yielding insights into risk stratification for pre-emptive genotyping implementation programs.

2548 | Predicting persistent high-dose opioid use after total knee replacement

Chandrasekar Gopalakrishnan[1], Jessica M Franklin[1], Yinzhu Jin[1], Daniel H Solomon[2], Jeffrey N Katz[3,2], Yvonne C Lee[4], Patricia D Franklin[5], Joyce Lii[1], Rishi J Desai[1] and Seoyoung C Kim[1,2]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [4]Northwestern University, Chicago, IL; [5]Northwestern University, Chicago, IL

Background: Patients undergoing total knee replacement (TKR) are at increased risk of persistent opioid use and dependence

Objectives: To identify patients with persistent high-dose opioid use after TKR using group-based trajectory models (GBTM) and determine predictors of persistent high-dose opioid users using pre-TKR patient characteristics

Methods: Using US Medicare Parts A, B and D claims (2010-2014), we identified patients aged ≥65 years who underwent a TKR and had no history of cancer or high-dose opioid use (>25 mean morphine equivalents (MME)/day) in the year prior. All patients were continuously enrolled in Medicare for ≥360 days prior to and ≥30 days after the TKR. To determine opioid filling patterns, patients were followed up to 360 days from the day of TKR. We modeled 12 monthly indicators of opioid prescription fills as a continuous (MME/day) variable using a censored normal GBTM and categorized patients into 4 groups. The primary outcome was persistent high-dose opioid use defined as patients in trajectory Group 3 (38.8 MME/day) or Group 4 (22.4 MME/day). We split the data into training (2010-2013 data) and test (2014 data) sets and used logistic regression to predict high-dose opioid use vs. low-dose opioid use (Groups 1 and 2) as a binary outcome utilizing pre-TKR patient characteristics as candidate predictors using the least absolute shrinkage and selection operator (LASSO) regression for variable selection. A reduced model with only 10 prespecified variables readily available for clinical use was also considered

Results: The final study cohort included 142,089 patients. The GBTM identified 4 distinct trajectories (Group 1- Short-term, low-dose, Group 2- long-term, low-dose, Group 3- medium-term, high-dose, Group 4-long-term, high-dose) of opioid use in the year after TKR. Using logistic regression and LASSO, we predicted the probability of persistent high-dose opioid use (N=17,171) in the training set (N=101,810) for an AUC=0.80. The AUC in the test set (N=40,279) predicting high opioid use (N=5,893) was 0.77. The final model selected 33 variables and identified baseline history of opioid use as the strongest positive predictor of high-dose persistent opioid use. The reduced model with only ten predictors also performed equally well (AUC=0.77)

Conclusions: In this cohort of older patients with no history of cancer or high-dose opioid use at baseline, 16.2% became high dose (28.1 MME/day) opioid users during the year after TKR. Our prediction model with 10 readily available clinical factors may help identify patients at high risk of future adverse outcomes from persistent opioid use and dependence after TKR

2556 | Trends in gabapentinoid prescriptions and coprescription with opioids in the four UK nations

Alvi Rahman[1,2], Joseph Kane[3], François Montastruc[4] and Christel Renoux[2,5]

[1]McGill University, Montreal, QC, Canada; [2]Lady Davis Institute for Medical Research, Montreal, QC, Canada; [3]Queen's University Belfast, Belfast, United Kingdom; [4]Faculty of Medicine and Toulouse University Hospital, Toulouse, France; [5]McGill University, Montreal, QC, Canada

Background: Gabapentinoid drugs, namely gabapentin and pregabalin, were approved in the United Kingdom in 1993 and 2004, respectively, for the treatment of epilepsy, neuropathic pain and generalised anxiety disorders (pregabalin). In the last decade, the rate of patients

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

newly treated with gabapentinoids has tripled but the potential differences in prescription and coprescription with opioids between the four UK nations is unknown.

Objectives: To estimate the annual rate of patients newly prescribed gabapentin and pregabalin in each UK nation (England, Northern Ireland, Scotland, and Wales) and the proportion of patients concomitantly prescribed opioids.

Methods: We used the Clinical Practice Research Datalink, a UK primary care database, to identify patients registered between 1993 and 2017. We fitted Poisson regression models to estimate the annual rate (per 100,000 person-years (PY)) of patients newly prescribed gabapentin and pregabalin in each UK nation, and the rate ratio (RR) from 2007 to 2017. We also calculated the proportion of patients with same-day coprescription with opioids.

Results: The annual rate of patients newly prescribed pregabalin increased steadily during the study period. Between 2007 and 2017, the rate rose from 118 to 351 per 100,000 PY (RR: 2.97; 95% CI: 2.85-3.11) in England, from 96 to 418 per 100,000 PY (RR: 4.37; 95% CI: 3.96-4.82) in Scotland, and from 104 to 370 per 100,000 PY (RR: 3.55; 95% CI: 3.23-3.91) in Wales. However, in Northern Ireland, we observed a rapid escalation from 546 (95% CI: 511-582) per 100,000 PY in 2007 to 1,139 (95% CI: 1,088-1,193) per 100,000 PY in 2010, at which point the rate was 5 times higher than in the other nations. This peak was followed by a decline to 532 (95% CI: 493-573) per 100,000 PY in 2017, but the rate remained higher than in the other nations. We observed a regular increase in patients newly prescribed gabapentin in England, Scotland, and Wales, which stabilized from 2015 onwards. In Northern Ireland however, following a plateau from 2005 to 2009, the rate of first gabapentin use sharply increased and surpassed rates in the other nations in 2017. The proportion of concomitant prescription of opioids remained relatively constant through the study period. In 2017, 16 to 19% of patients newly prescribed gabapentinoids in each of the four nations were concomitantly prescribed opioids.

Conclusions: Since their introduction in the UK, the use of gabapentinoids has notably increased in all nations, more so in Northern Ireland with an unprecedented peak in pregabalin prescriptions. A substantial proportion of patients were concomitantly prescribed opioids in all nations.

2574 | Incidence of anorexia nervosa and the prescribing of psychotropic medications from UK Primary Care, 1996-2016: A retrospective database study

Maedeh Y Beykloo[1], Dasha Nicholls[2], Ian Wong[1], Mima Simic[3], Elizabeth Mills[1] and Ruth Brauer[1]

[1]University College London (UCL), London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]South London and Maudsley NHS Foundation Trust, London, United Kingdom

Background: Anorexia nervosa (AN) is a psychiatric disorder characterised by restrictive eating and an intense fear of weight gain (1). The most recent study reporting the incidence of AN was conducted using primary care records from 2000 to 2009 and found the incidence to be stable by gender despite minor fluctuations across the years (2). There is currently a lack in evidence for the efficacy of psychotropic medications in AN, however, they are sometimes prescribed if there is a less than optimal treatment response with first line psychological treatments.

Objectives: This study aimed to comprehensively assess trends in the incidence of AN in order to provide up-to-date results and to measure the use of psychotropic medications in individuals with AN over two decades.

Methods: A retrospective database study was conducted using The Health Improvement Network (THIN) database which consists of anonymised medical records from general practices throughout the UK. Individuals aged 12-50 years and with recorded AN diagnosis were identified between 1996 and 2016. The incidence of AN were calculated annually and Kaplan Meier analyses were used to measure the prescribing duration and cessation of psychotropic medications in this cohort.

Results: A total of 17,597 individuals were identified from 1996-2016, of which 80.28% were females. The incidence of AN remained fairly constant for females and males from an overall incidence of 15.21/100,000 person years in 1996, to 21.84/100,000 person years in 2006, followed by a decrease in 2016 to 18.25/100,000 person years. Almost half of individuals with AN (47.44%) received a prescription for psychotropic medication in the study period. Most individuals receiving medication were prescribed antidepressants (98.13%), whilst under a fifth (17.29%) were prescribed antipsychotics, which is in line with our previous study (3). The most common antidepressant prescribed was fluoxetine (59.73%) and the most common antipsychotic was olanzapine (8.90%). Under half of individuals (46%) initiated on a psychotropic medication continued with a psychotropic prescription after six months.

Conclusions: This study provides the most up-to-date trends for AN incidence and highlights the use of psychotropic medications for the treatment of AN in UK primary care, despite lack of sufficient evidence. As our study is limited to patient data as recorded in primary care, we call for greater investigations into the benefits and harms associated with psychotropic medications in this population.

2619 | The impact of changing biosimilar policies for rheumatic conditions and inflammatory bowel disease in Ontario, Canada

Mina Tadrous[1], Daniel McCormack[2], Sophie Kitchen[3], Martins Diana[3] and Tara Gomes[3]

[1]Women's College Hospital, Toronto, ON, Canada; [2]ICES, Toronto, ON, Canada; [3]Ontario Drug Policy Research Network, Toronto, ON, Canada

Background: Biologic drugs are important treatment options for several conditions, including rheumatic conditions, gastrointestinal disease, and diabetes. Yet, these medications are associated with high costs. Recently available biosimilars are similar, lower cost medications

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with no clinically meaningful differences compared to their innovator biologics. Two drugs currently have available biosimilars but are listed differently. We sought to determine the impact on biosimilar utilization when different listing strategies are used.

Objectives: We sought to determine the impact on biosimilar utilization when different formulary listing strategies are used.

Methods: We conducted a population-based time-series study between January 2010 and June 2019 to assess the quarterly utilization of biologics used for the treatment of rheumatic conditions and inflammatory bowel disease (IBD) with currently available biosimilars (etanercept and infliximab) through the public drug program in Ontario, Canada. Utilization was defined as the number of individuals who were dispensed a prescription for a publicly-funded biologic or biosimilar per quarter. Trends in utilization and expenditures for biologics were forecasted to June 30, 2022. We used Holt-Winters' exponential smoothing models to forecast utilization and costs.

Results: Between Q1 2010 and Q2 2019, the number of biologic users for rheumatic and IBD indications increased by 133% from 5,225 to 12,178 users. Among biologics indicated for rheumatic conditions and IBD with a currently available biosimilar, 16.7% of users (N=1,196 of 7,158) were treated with a biosimilar in Q2-2019. By Q2-2022, this was similar for both drugs. It is estimated that 2,717 users (95% CI: 1,899, 3,536) out of 8,142 biologic users (95% CI: 7,438, 8,847) with a currently available biosimilar will be treated with biosimilars, representing a proportion of 35.1% (95% CI: 24.5%, 45.6%).

Conclusions: The utilization of biologic drugs for rheumatic and IBD indications are substantial and expected to rise over time. Biosimilars current uptake is low and did not different greatly between drugs. Traditional formulary-based policies may not be effective at significantly altering biosimilar uptake.

2633 | Trends in oral anticoagulant co-prescription with antiepileptic drugs among adults with epilepsy, 2010-2018

Emily K. Acton[1,2,3], Allison W. Willis[1,2,4,3], Michael A. Gelfand[4], Sean Hennessy[3,1,5], John R. Pollard[4,6] and Scott E. Kasner[4]

[1]*University of Pennsylvania School of Medicine, Philadelphia, PA;* [2]*University of Pennsylvania School of Medicine, Philadelphia, PA;* [3]*University of Pennsylvania School of Medicine, Philadelphia, PA;* [4]*University of Pennsylvania, Philadelphia, PA;* [5]*University of Pennsylvania School of Medicine, Philadelphia, PA;* [6]*ChristianaCare, Newark, DE*

Background: Adults with epilepsy often have pro-thrombotic conditions necessitating concurrent treatment with antiepileptic drugs (AEDs) and oral anticoagulants (OACs). However, with growing evidence that many widely used AEDs interact with warfarin, and potentially with newer direct oral anticoagulants (DOACs), treatment considerations for epilepsy patients requiring anticoagulation are changing, and actual prescribing practices are not well understood.

Objectives: To estimate the prevalence and characterize the patterns of outpatient prescriptions for concurrent OACs and AEDs in adults with epilepsy.

Methods: We conducted a retrospective assessment of OAC and AED dispensing using the 2010-2018 OptumInsight Clinformatics™ Data Mart, a large claims database. Included enrollees were 18 years of age or older with ICD-9/10 codes for epilepsy. Episodes of AED use lasting ≥14 contiguous days in a given year were counted and classified in terms of presence of ≥1 enzyme-inducing AEDs (EI-AEDs, potentially interacting), or presence of only non-enzyme inducing AEDs (NEI-AEDs, presumably non-interacting). Annual prevalences of contiguous, concomitant prescriptions for OACs with AEDs for ≥14 days were compared over successive years with the Cochran-Armitage test for trend. Multivariable logistic regression was used to evaluate the associations of sociodemographic characteristics with concomitant prescribing patterns.

Results: Among adults with epilepsy on studied AEDs, the prevalence per 1,000 patients of concurrent OACs increased from 58.4 in 2010 to 92.0 in 2018 (odds ratio (OR) 1.63, confidence interval (CI) 1.58-1.69; P<0.001). DOAC use in this population rapidly increased from 2010 to 2018, with yearly % changes in co-dispensing with AEDs of +0.29, +0.30, +0.41, + 0.57, +0.59, +0.84, +1.06, +1.31 (P < 0.001). Simultaneously, warfarin use with AEDs decreased, with yearly % changes of +0.02, -0.01, -0.08, -0.35, -0.30, -0.20, -0.34, -0.39 (P < 0.001). In 2018, DOACs were less likely than warfarin to be co-dispensed with potentially interacting EI-AEDs versus NEI-AEDs alone (OR 0.67, CI 0.63-0.72). Characteristics independently associated with ≥1 episode of concurrent EI-AED use with OACs in 2018 were older age, female sex, white race, and net worth <$250K.

Conclusions: The rapid rise in the concomitant use of OACs with AEDs, including those with demonstrated warfarin and potential DOAC interactions, highlights the need to better characterize and optimize prescribing practices for the concomitant use of these drug classes.

2651 | Correlation between antibiotic consumption and resistance at an intensive care unit in Serbia

Radmila Popović[1], Ana Tomas[2], Sanja Vicković[1], Gordana Jovanović[1], Olga Horvat[2], Zdenko Tomić[2] and Ana Sabo[2]

[1]*University of Novi Sad, Novi Sad, Serbia;* [2]*University of Novi Sad, Novi Sad, Serbia*

Background: The paucity of information on quantity and quality of antimicrobial prescribing is one of the important barriers to the successful development and implementation of antimicrobial stewardship programs in Serbia.

Objectives: To describe antimicrobial prescribing practices and antimicrobial resistance among gram negative pathogens and to relate exposure to antimicrobials to the development of antimicrobial resistance.

Methods: A retrospective, observational study was performed in an intensive care unit in the largest tertiary health care center in Vojvodina, Serbia from 2014 to 2018. Antibiotic prescription data were analysed according to the WHO anatomical therapeutic chemical (ATC)/defined daily dose (DDD) methodology; antibiotic resistance

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

was expressed as incidence density adjusted for total inpatient-days, Targeted organisms included Klebsiella pneumoniae, Pseudomonas aeruginosa and Acinetobacter spp. Individual trends were determined by linear regression, while possible associations between antibiotic prescription and resistance were evaluated using cross-correlation analysis.

Results: Overall decrease in antibiotic utilization was observed. The prescription rates of piperacillin-tazobactam increased significantly, while consumption of 3rd and 4th generation cephalosporins and fluoroquinolones decreased. Results over 5 years indicated significantly rising incidence densities of doripenem resistant Acinetobacter spp., piperacillin/tazobactam resistant P. aeruginosa and doripenem, ertapenem, meropenem and colistin resistant Klebsiella pneumoniae. Cross-correlation analysis demonstrated positive association between the use of glycopeptides (R=0.76) and resistance to piperacillin/tazobactam in P. aeuruginosa. Strong positive correlation (R=0.97) has been found between the colistin use and resistance to doripenem in Acinetobaccter spp. For K. pneumoniae, resistance to colistin was strongly positively associated with use of colistin (R=0.89), carbapenems (R=0.73) and imidazoles (R=0.75). Positive association between the use of colistin and carbapenems and carbapenem resistance in K. pneumoniae was identified. There was an inverse relationship between the use of 1st and 2nd generation cephalosporins with the resistance to colistin and carbapenems in K. pneumoniae.

Conclusions: In conclusion, our data demonstrated increase in resistance and a correlation between prescription of and Gram-negative bacterial resistance to several antimicrobial agents in Serbian hospital.

2657 | Sensitivity of treatment patterns to grace period selection in medications with tolerability issues: A real-world example of hedgehog inhibitor use in basal cell carcinoma

Wenzhen Ge[1], Ning Wu[1], Chieh-I Chen[1], Matthew G Fury[1], Emily Ruiz[2] and Jessica J Jalbert[1]

[1]*Regeneron Pharmaceuticals, Inc., Tarrytown, NY;* [2]*Brigham and Women's Hospital, Boston, MA*

Background: Hedgehog inhibitors (HHIs) are oral targeted therapies approved for the treatment of advanced basal cell carcinoma (BCC). As patients commonly experience adverse events that may be managed through treatment interruptions, we hypothesized that HHI treatment patterns may be sensitive to grace period (GP) duration.

Objectives: To assess the impact of GP selection on patterns of HHI treatment interruptions (TI), treatment duration, and re-initiations (RI) among patients with BCC.

Methods: This was a retrospective cohort study using MarketScan Commercial/Medicare databases (01/01/2013-09/30/2018). We identified new users of HHIs (index date = date of the first dispensation), ≥18 years of age who were continuously enrolled for ≥6 months prior to the index date (i.e. baseline) with ≥1 baseline BCC diagnosis. TIs were defined as a lack of dispensation following the exhaustion of days' supply and allotted GP. RI was defined as ≥1 HHI dispensation after TI. The Kaplan-Meier method was used to estimate time to HHI TI and, among patients with a TI, incidence of RI. HHIs are generally dispensed in 30-days' supply and indicated as long as a patient derives a clinical benefit, however, since TIs are commonly employed during HHI therapy, sensitivity analyses were conducted using GPs of 14, 30, 60, 90 and 120 days.

Results: We identified 469 patients with a BCC diagnosis initiating HHIs. The mean (SD) age was 67.6 (15.8) years, 64.2% were men, 51.2% were covered by commercial insurance and 99.2% initiated vismodegib. Using a GP of 14, 30, 60, 90 and 120 days, the risk of HHI TI was 79.2%, 68.8%, 60.0%, 55.4% and 51.4% at 6 months and 94.8%, 91.3%, 88.2%, 83.2% and 80.2%, at 1 year, respectively. Median HHI treatment duration ranged from 94 days (95% CI: 90-109) using a GP of 14 days to 173 days (95% CI: 156-194) using a GP of 120 days. At 6 months following TI, incidence of RI was 35.8%, 19.8%, 11.3%, 6.9% and 4.9% using a GP of 14, 30, 60, 90 and 120 days, respectively. The incidence of HHI RI at 1-year following TI ranged from 40.8% using a 14-day GP to 13.4% using a 120-day GP.

Conclusions: Characterizing real-world persistence on HHIs is challenging due to the use of drug holidays, as TIs, treatment duration, and RIs were sensitive to the duration of the GP selected. Real-world studies of medications with tolerability issues should consider the use of drug holidays in order to accurately characterize drug exposures.

2661 | Medication of diabetes in middle-aged and elderly: Survey data from the china health and retirement longitudinal study (CHARLS)

Lili Liu, Shengfeng Wang and Siyan Zhan

Peking University, Beijing, China

Background: Compared to the increasing prevalence of diabetes in middle-aged and elderly, the blood glucose control rate is extremely low. Medication with lifestyle intervention was recommended in the national guideline for the prevention and control of diabetes in primary care (2018).

Objectives: This study aims to provide reliable estimates of medication trends and related influencing factors in the middle-aged and elderly diabetes in China.

Methods: The China Health and Retirement Longitudinal Study (CHARLS) is a cross-sectional survey using a four-stage, stratified, cluster sampling to select eligible individuals. We analyzed the wave1-3 national survey data from 2011~2016. Diabetes was considered as a fasting plasma glucose ≥ 126mg/dl or a glycosylated hemoglobin (HbA1c) ≥ 6.5% or self-reporting. Multivariable logistic regressions were used to identify medication related influencing factors. The ethics committee of Peking University Health Science Center approved this study, and all participants gave written informed consent before participation.

Results: From 2011 to 2016, the age standardized prevalence of diabetes increased from 13.04% to 16.20% in all respondents ≥ 45 years included. The medication rate was similarly going up from 30.08% to

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

33.97%, and utilization rates of both western medicine and insulin were increasing, except slightly decline of traditional Chinese medicine. Among all patients with diabetes in 2015~2016, only 1323 (19.27%) had been examined by community/village doctors regularly. In the medication, only 1172(33.97%) of whom were treated with medicine (68.94% with western medicine, 24.23% with insulin, and 6.83% with traditional Chinese medicine). After controlling for covariates, heart disease, drink and type of residents are significantly influenced the medication of diabetes. Compared with patients without medication, the patients with medication drunk more frequently in daily life (OR = 1.71, [95% CI 1.34-2.18]). Meanwhile, obesity, highly educated and those with heart disease were more likely to take medicine.

Conclusions: The medication rate of diabetes in the Chinese middle-aged and elderly population is delightfully increasing, despite the prevalence rises unsatisfactorily. In the future, we should strengthen the education of life intervention and chronic disease management, promote the blood glucose control rate, and then to improve the quality of life.

2667 | Drug utilization for symptom management by patients with multiple sclerosis by phenotype in Germany

Denise Oleske, 60064[1], Lou Barbato[2] and Bruce Barger[3]
[1]*AbbVie, Inc, North Chicago, IL;* [2]*AbbVie, Inc, North Chicago, IL;* [3]*AbbVie, Inc, North Chicago, IL*

Background: Knowledge of drug utilization for symptom management by multiple sclerosis (MS) phenotype provides context for safety assessments and potentially impacts efficacy profiles of new disease modifying therapies in development for MS. Little information exists about non-disease modifying drug utilization by MS phenotype owing to the relative rarity of some of its subtypes. Data from a large health insurance claim database in Germany where MS phenotype diagnosis coding has been in place for nearly 20 years can provide reliable insight into the current drug use for symptom management.

Objectives: To evaluate drug utilization for symptom management in patients with MS by disease phenotype.

Methods: This observational study used data from Betriebskrankenkassen. It is comprised of those with Statutory Health Insurance (SHI) in Germany containing adjudicated healthcare claims data on more than 5 million patients (7% of the German SHI population) who are representative, in terms of age and sex, to the larger insured population. Female and male patients aged 18+ years having ≥1 MS diagnosis (ICD-10-GM codes G35.0, G35.1, G35.2, G35.3, or G35.9) and who were continuously enrolled within 2017 are included. The first MS diagnosis is considered for the assignment into the phenotype grouping. Drugs in the database were coded by the WHO Anatomical Therapeutic Chemical (ATC) classification. Chi-square tests evaluated the significance of proportions and ANOVA for continuous variables.

Results: Of those whose MS phenotype was specified (n=7,814), 78.8% had the relapsing remitting (RRMS) form, 15.1% with the secondary progressive (SPMS) form, and 6.1% with primary progressive (PPMS). There was no significant difference among the groups regarding gender. RRMS patients were significantly younger compared to those with SPMS or PPMS ($P<0.01$, for both comparisons). Antidepressants were the most commonly prescribed drug class (RRMS, 24.7%, SPMS, 34.2%, PPMS, 31.1%). A significantly ($P<0.05$) higher proportion of patients with SPMS or PPMS were prescribed antiepileptics, muscle relaxants, urinary antispasmodics, or medications to manage fatigue than RRMS patients. No differences among the three groups were noted for the proportion of prescriptions for anti-dementia drugs, tremor, gastrointestinal disorders, hypnotics or sedatives, or anti-Parkinson drugs.

Conclusions: Some different drug utilization patterns emerged by MS phenotype. More patients with SPMS or PPMS were prescribed drugs for symptom management than those with RRMS. Antidepressants were the most commonly prescribed regardless of MS phenotype.

2672 | Factors associated with concurrent use of prescription opioids and benzodiazepines: A population-based assessment

Erin Y Liu[1], Robyn Tamblyn[1], Kristian B. Filion[1,2] and David L. Buckeridge[1]
[1]*McGill University, Montreal, QC, Canada;* [2]*Jewish General Hospital, Montreal, QC, Canada*

Background: Opioid overdoses have resulted in over 700,000 deaths in North America over the last 20 years. Concurrent use of opioids and benzodiazepines has emerged as a risk factor for these deaths. Given this safety concern, we seek to characterize patients who are prescribed these drugs concurrently.

Objectives: To identify characteristics associated with the concurrent use of prescription opioids and benzodiazepines.

Methods: We conducted a nested case-control analysis within a retrospective cohort of 193,512 new prescription opioid users from 2000 to 2014. The source population was a 25% random sample of residents from Montreal, Canada who had linked data on patient demographics, inpatient and outpatient physician billings, hospitalizations, and dispensed medications. We used risk-set sampling to match cases, defined as concurrent users of opioids and benzodiazepines, to 5 controls on follow-up time and cumulative days' supply of prescription opioids. We defined a concurrent user as anyone with at least 1 day of overlap between dispensed prescriptions for an opioid and benzodiazepine. The first date of concurrent use defined the index date. We used conditional logistic regression to identify patient demographic and clinical characteristics associated with concurrent use.

Results: Cohort members were followed for a mean of 4.9 years. A total of 41,274 patients (21.3%) became concurrent users. The average age of concurrent users was 61.8 years and 64.7% were female. A total of 54.9% of concurrent users were prescribed their opioid and benzodiazepine from different physicians. Previous long-term (60 or more days vs 1-30 days) use of benzodiazepines (OR 3.31, 95% CI 3.13-3.49), 2 vs 1 opioid prescribers (OR 2.46, 95% CI 2.11-2.85),

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

opioid dependence/abuse (OR 1.96, 1.22-3.17), and opioid overdose (OR 1.49, 95% CI 0.90-2.47) at cohort entry, alcohol dependence/abuse (OR 1.48, 95% CI 1.33-1.64) and drug insurance plan for social deprivation (OR 1.40, 95% CI: 1.32-1.49) were highly associated with concurrent use. Non-opioid drug dependence/abuse (OR 1.30, 1.19-1.42), having an opioid prescriber who was a doctor vs dentist (OR 1.17, 95% CI 1.10-1.24) and initiating an opioid prescription that lasted more than 7 days (OR 0.85, 95% CI 0.81-0.88) were modestly associated, whereas age, sex, average daily dose of initiating opioid, and mental health disorders were minimally or not associated.

Conclusions: Concurrent users are more likely to be chronic users of benzodiazepines, have multiple opioid prescribers, be socially deprived, and have a substance use disorder.

2681 | Asthma maintenance medication users in the sentinel distributed database

Marie C Bradley[1], Elnara Fazio-Eynullayeva[2], Yan Li[3], Jianmeng Chen[4], Stacy Chin[4], Sandra Deluccia[2], Efe Eworuke[1], Katherine Freitas[2], Judith Maro[2], Catherine A Panozzo[2], Yunzhao Ren[5], Chandrahas Sahajwalla[6], Rongmei Zhang[7], David Martin[8], Sally Seymour[9], Kenneth Quinto[9] and Robert Busch[9]

[1]FDA, Silver Spring, MD; [2]Harvard Pilgrim Health Care Institute and Harvard Medical School, Boston, MA; [3]FDA, Silver Spring, MD; [4]FDA, Silver Spring, MD; [5]FDA, Silver Spring, MD; [6]FDA, Silver Spring, MD; [7]FDA, Silver Spring, MD; [8]FDA, Silver Spring, MD; [9]FDA, Silver Spring, MD

Background: Recent legislation mandates that the US Food and Drug Administration evaluate the potential use of real-world evidence (RWE) to support regulatory decision making. The feasibility of using the Sentinel Distributed Database (Sentinel) to evaluate comparative effectiveness and safety of asthma maintenance medications (AMM) in real world settings is unclear.

Objectives: To examine demographic and clinical characteristics of asthma patients dispensed AMM in Sentinel.

Methods: We conducted a retrospective cohort study in Sentinel from 2008 to 2018. We defined asthma patients as enrollees aged 18 years or greater with an index event of an ICD-9 or -10 code for asthma and with 1 or more dispensings of AMM during the 12 months prior to the index event (baseline period). AMM included inhaled corticosteroids (ICS), long-acting beta-agonists (LABA), long-acting muscarinic antagonists (LAMA), inhaled combination products, leukotriene receptor antagonists (LTRA), and biological products for asthma. Asthma patients with ICD codes for common respiratory comorbidities in the baseline period were excluded. We calculated summary statistics for selected demographic and clinical characteristics during the 12-month baseline period and 12-month follow-up periods.

Results: A total of 3.32 million asthma patients met our eligibility criteria; their mean age was 57 years (standard deviation [SD] = 15.2 years) and 69.3% were female. During the baseline period, the mean Charlson/Elixhauser combined comorbidity score was 1.8 (SD = 1.8), and the mean number of ambulatory encounters and filled prescriptions were 19 (SD = 16.4) and 42.3 (SD = 35.5), respectively. In the combined baseline and follow-up periods, the proportion of patients that filled ≥2 prescriptions for ICS was 34.1%, for ICS/LABA combination products was 43.8%, and for LTRA 37.2%. During the follow-up period, 14% of patients had ≥1 respiratory event coded as asthma exacerbation (AEx), 37.9% of patients filled ≥1 oral corticosteroid (OCS) prescriptions, and 1.9% had an AEx that required hospitalization.

Conclusions: To our knowledge, these data represent the first comprehensive characterization of asthma patients in Sentinel. The burden of healthcare encounters, prescriptions, and comorbidities provides insight on the health status of these asthma patients. The inconsistency between the proportion of patients with ICD codes for AEx and the proportion filling OCS prescriptions warrants further examination. These exploratory data inform the feasibility of using Sentinel for future analyses of the potential benefits and risks of asthma medications.

3717 | Utilization of spironolactone in patients with reduced or preserved ejection fraction heart failure

Sruthi Adimadhyam[1], Austin Cosgrove[1], Qoua L. Her[1], Jennifer Lyons[1] and Efe Eworuke[2]

[1]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [2]Food and Drug Administration, Silver Spring, MD

Background: Spironolactone is an aldosterone antagonist indicated for the management of reduced ejection fraction (rEF) heart failure (HF). In the TOPCAT trial, spironolactone significantly lowered the incidence of HF hospitalizations among patients with preserved ejection fraction (pEF) HF. Real world utilization of spironolactone in pEF is unknown.

Objectives: To evaluate the use of spironolactone following a diagnosis of rEF or pEF and characterize the first treatment episode.

Methods: We conducted a retrospective cohort study using data from the MarketScan® Research Databases (7/2010 - 9/2018). We identified patients with rEF or pEF using diagnosis and procedure codes from a previously validated algorithm. Patients with a diagnosis of left or systolic HF with a history of cardiomyopathy, implantable cardioverter defibrillator, or myocardial infarction in 183 days prior HF diagnosis were classified as rEF, while those with diastolic or unspecified HF with no history of cardiomyopathy or implantable cardioverter defibrillator were classified as pEF. We required patients to be continuously enrolled in the 183 days prior to cohort entry and have no history of spironolactone use. Follow-up started on the day of diagnosis and ended at the earliest occurrence of a spironolactone dispensing, disenrollment, death, or end of data. We calculated the proportion of HF patients initiating spironolactone. For those initiating treatment, we estimate the dose and duration of the first treatment episode. Results were stratified by age group, sex, and year of HF.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 178,334 patients with rEF, 65.3% were male, and mean age was 68.5 ± 14.6 years. Among 1,361,449 patients with pEF, 49.8% were male, and mean age was 64.4 ± 15 years. Proportion of patients that initiated spironolactone following rEF was 17.2% versus 4.2% after pEF. The median time to initiation of spironolactone after rEF was 79 (12 - 319) days versus 226 (40 - 668) days after pEF. The median duration of first treatment episode in rEF was 120 (34 - 306) days with a median dose of 25 (25 - 25.3) milligrams/day. The median duration of first treatment episode in pEF was 100 (30 - 271) days with a median dose of 25 (25 - 50) mg/day.

Conclusions: Our study indicates low utilization of spironolactone in patients with pEF compared to rEF. Future utilization studies will be needed to evaluate the influence of the TOPCAT trial findings in the management of patients with pEF HF. We intend to replicate this study in the Sentinel Distributed Database.

3738 | How marketing approval changed the use of tranylcypromine in the Netherlands

Angela van der Salm, Magdalena Gamba and Toine Egberts
Utrecht University, Utrecht, Netherlands

Background: Tranylcypromine (TCP) is an old MAO-inhibitor used in patients with treatment-resistant depression. It was taken off the market due to its safety profile in the mid-1960's and later reintroduced but only available in the Netherlands on a named patient basis. Since June 2016 it is available again as authorized medicine.

Objectives: Our aim was to investigate differences in patient characteristics of TCP users on a named patient basis versus those taking the authorized medicine.

Methods: From the Out-patient Pharmacy Database of the PHARMO Database Network, all patients were identified to whom TCP had been dispensed between 1 January 2009 and 31 December 2018. Patients were divided into 3 groups: new users up to July 2016 (new user-pre; using TCP on a named patient basis), new users after June 2016 (new user-post; using authorized TCP), and patients that switched from named patient TCP to authorized TCP after June 2016 (switchers).

Patient characteristics of interest included age, gender, prescriber specialty, concomitant use of cardiovascular (CV) medication, and history of antidepressant (CNS) drug use.

Results: There were 529 patients in the new user-pre group, 216 patients in the new user-post group, and 186 patients switched. The three groups showed a similar mean age (54 years; with switching occurring at the age of 59 years), and gender distribution (33% men vs 67% women). The vast majority of prescriptions was done by psychiatrists/specialists, but in switchers, TCP was prescribed three times more frequently by general practitioners (36% vs 12-13%).

In the new user-post group, 36% of patients used 1 or more CV medications, vs 30% in the new user-pre group, and only 6% in switchers. TCP was prescribed to patients that did not meet the label requirement (i.e. previous use of two other antidepressants and lithium; ≥ 3 other CNS drugs) 1.5 times (95% CI of 1.02 to 2.17) more often in the new user-pre than in the new user post-group (22% vs 14%).

Conclusions: This study has shown that characteristics of patients using TCP changed after the availability changed from a restricted named patient basis to an authorized medicine. Our results indicate a lack of specialist monitoring during switching, and improved but residual lack of adherence to the label requirement for initiating treatment.

3761 | Trend of pattern change of antihypertensive medications using real-world data in Korea

Minji Jung, Eunjung Choo and Sukhyang Lee
Ajou University, Suwon, Republic of Korea

Background: The prevalence of hypertension in persons older than 30 years is as high as 30% in Korea. Hypertension is a risk factor of cardiovascular disease, which is the leading cause of mortality in globally, as well as Korea. Antihypertensive treatments can lower high blood pressure and prevent stroke, heart attacks, heart failure, or kidney disease.

Objectives: To estimate the actual status of antihypertensive medication use and patterns based on drug exposure preparation algorithm using national claims data in Korea.

Methods: We obtained national claims data from the Health Insurance Review and Assessment Service (HIRA), which covers almost all Koreans. A total of 11,193,969 patients were included after being used antihypertensive drugs at least 30 consecutive days from 2015 to 2018. We included both inpatients and outpatients in all ages.

Results: During the study period, patients with monotherapy were 48.1%, dual therapy were 38.0% and more than triple therapy were 13.8%. Among mono therapy, angiotensin II receptor blockers (ARBs) (34.7%) and calcium channel blockers (CCBs) (32.5%) were the most frequently prescribed classes. Male subjects accounted for 50.4% of the study populations. To compare patients prescribed antihypertensive medications in 2016 with those in 2015, 75.1% of study patients maintained their treatments, 8.3% newly started, 5.8% added to different classes of antihypertensives, 5.4% discontinued and 5.4% switched to other classes. Of those with maintained therapy, ARBs (37.6%) and CCBs (32.9%) were the most frequently prescribed classes.

Conclusions: We evaluated antihypertensive medication use and trend to achieve further improvement in hypertension treatment.

3771 | Changes in prescribing of hormone replacement therapy in Germany between 2004 and 2016

Miriam Heinig[1], Malte Braitmaier[1] and Ulrike Haug[1,2]
[1]*Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany*; [2]*University of Bremen, Bremen, Germany*

Background: After publication of the Women's Health Initiative's (WHI) findings in 2002, short-term studies suggested a drastic

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

decrease in the use of hormone replacement therapy (HRT), but studies on longer-term trends and details of use are scarce.

Objectives: To describe trends and details of HRT use based on German claims data over a span of thirteen years.

Methods: We used the German Pharmacoepidemiological Research Database (GePaRD) containing health insurance claims data from ~25 million persons since 2004. We determined the prevalence of any as well as type-specific (combined vs. estrogen-only) HRT prescriptions by route of administration and age. We additionally compared the total number of Defined Daily Doses (DDDs) prescribed to HRT users within 5 years between different time periods (2005-2009 vs. 2012-2016).

Results: Between 2004 and 2016, the prevalence of any type of HRT prescription decreased by 46% in women aged 50 years and was 96 per 1000 in 2016. In women aged 60 years, it decreased by 49% (153 per 1000 in 2016) and in women aged 70 years it decreased by 35% (134 per 1000 in 2016). The prevalence of oral combined HRT prescriptions decreased by 72%, 72%, and 61% in women aged 50, 60 and 70 years between 2004 and 2016 (22, 32 and 19 per 1000 in 2016), respectively. With respect to prescription of estrogen-only HRT, the prevalence and time trends varies according to route of administration. Comparing the prevalence among women aged 50, 60, and 70 years, respectively, in 2016 to 2004 the pattern was as follows: A) oral estrogen -79%, -74%, and -59% (5, 13 and 16 per 1000 in 2016); B) transdermal estrogen +/- 0%, -43% and -42% (25, 27 and 20 per 1000 in 2016); C) vaginal estrogen: -6%, +8% and +3% (32, 85 and 83 per 1000 in 2016). Prevalence of oral gestagen HRT prescriptions (usually combined with an estrogen) increased by 44% and 60% in women aged 50 and 60 years (27 per 1000 and 11 per 1000 in 2016), respectively, and decreased by 10% in 70-year-old women (4 per 1000 in 2016).

Comparing the time periods 2012-2016 to 2005-2009, the median total number of Defined Daily Doses (DDDs) prescribed to 50, 60 and 70-year-old HRT users in the next 5 years decreased by 8%, 32% and 12% for any HRT. For combined oral HRT it decreased by 33% in 50-54-year-old women, increased by 3% in 60-64-year-old women, and did not change in women 70-74 years.

Conclusions: For most types of HRT, prevalence of prescriptions declined considerably between 2004 and 2016 in Germany. In 2016, 10-15% of women aged 50-70 were prescribed any HRT. The fairly high prevalence in 70-year-old women is mainly due to vaginal estrogen.

3787 | Antidiabetic medication use in children and adolescents from 2004 to 2019: Real world data from a commercially insured population in the United States

Jenny W Sun[1], Sonia Hernández-Díaz[1], Florence T Bourgeois[2], Sebastien Haneuse[3], Brian T Bateman[4], Elisabetta Patorno[4] and Krista F Huybrechts[4]

[1]Harvard T.H. Chan School of Public Health, Boston, MA; [2]Boston Children's Hospital and Harvard Medical School, Boston, MA; [3]Harvard T.H. Chan School of Public Health, Boston, MA; [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Background: Over the past several decades, the incidence and prevalence of type 2 diabetes in children and adolescents has nearly doubled, yet little is known about the use of antidiabetic medications and the uptake of newer agents.

Objectives: To describe the patterns of non-insulin antidiabetic medication use and initiation in children and adolescents.

Methods: Using real world data from the Optum© Clinformatics® Data Mart (January 2004-June 2019), we identified a cohort of pediatric patients (10-18 years) and evaluated changes over time in non-insulin antidiabetic medication use overall and by class. Then, we identified new users of non-insulin antidiabetic medications and followed patients until the end of insurance coverage or end of available data. Among new users, we evaluated trends over time in the proportion of patients who initiated metformin compared to other antidiabetic agents, and examined time to discontinuation using a Kaplan-Meier analysis.

Results: In a cohort of over 1 million pediatric patients, the prevalence of any non-insulin antidiabetic medication use was 70.3 per 100,000 patients in 2004 and doubled to 145.0 per 100,000 in 2019. Across all years, biguanides (metformin) was the most widely used medication class, with the prevalence per 100,00 patients increasing from 63.2 in 2004 to 140.0 in 2019. The second most widely used class was thiazolidinediones from 2004-2011 and glucagon-like peptide-1 agonists from 2012-2019, but the prevalence was low in these classes (<10 per 100,000). There were 16,433 new users of non-insulin antidiabetic medications between 2004 and 2019 (mean age at initiation: 14.6 years). Metformin represented 89.3% of initiations in 2004 and rose to 97.3% of initiations in 2019. Recently, the second most frequently initiated antidiabetic was liraglutide (1.1% in 2018, 1.3% in 2019). After treatment initiation (mean follow up: 2.5 years), patients filled a median of 2 (interquartile range [IQR]: 0-6) subsequent non-insulin antidiabetic prescriptions. No refills were observed in 27% of initiators. Patients continuously used any antidiabetic for a median of 67 days (IQR: 30-154).

Conclusions: The use of non-insulin antidiabetic medications in children and adolescents has increased substantially between 2004 and 2019. Nearly all patients initiated metformin, which is consistent with treatment guidelines, whereas use of newer agents remains low. Short treatment periods were observed, which justifies further research to assess whether this represents undertreatment or switch to non-pharmacologic treatment options.

3799 | Use of levothyroxine for the treatment of subclinical hypothyroidism among pregnant women in the United Kingdom: A population-based assessment

Ya-Hui Yu[1,2], Sonia M Grandi[3], Robert W Platt[1,2], Oriana HY Yu[2] and Kristian B Filion[1,2]

[1]McGill University, Montreal, QC, Canada; [2]Jewish General Hospital, Montreal, QC, Canada; [3]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Subclinical hypothyroidism (SCH) affects 2.5% of pregnant women. Although clinical guidelines recommend levothyroxine to sustain optimal fetal growth in women with hypothyroidism, its use among pregnant women with SCH is poorly understood.

Objectives: To describe levothyroxine prescription patterns among pregnant women with SCH and to identify characteristics associated with levothyroxine use in a population-based cohort of women in the United Kingdom.

Methods: Our study cohort used linked data from the Clinical Practice Research Datalink, its pregnancy register, and Hospital Episode Statistics. We included pregnancies of women diagnosed with SCH in the year before or during pregnancy from 1998 to 2017. Cohort entry was defined by the date of SCH diagnosis or by the start of pregnancy, whichever occurred last. Levothyroxine use was defined as ≥1 prescription during pregnancy. We used multivariable logistic regression to estimate characteristics associated with levothyroxine use, including age, race/ethnicity, socioeconomic status, obesity, smoking, alcohol use, diabetes, hypertension, infertility, rheumatoid arthritis, polycystic ovary syndrome, obstetric history, and thyroid-simulated hormone (TSH) level.

Results: Our cohort included 18,113 pregnancies from 15,949 women with SCH. A total of 3,152 (17%) pregnancies from women with SCH received levothyroxine. The average daily dosage of the first prescription during pregnancy was 50-75 mcg in 33% of women and ≥75 mcg in 49% of women. The majority of women were first prescribed levothyroxine in the first trimester (76%). The overall median treatment duration was 185 days (IQR: 84, 256). Among women newly diagnosed with SCH during pregnancy, the initial prescription was, on average, a higher dosage and a shorter duration than among women with prevalent SCH. The levothyroxine prescription rate varied with calendar year; rates decreased from 24% to 17% in 1999 and 2000, remained stable until 2015, when it rose to 20% and then to 24% in 2016. Characteristics independently associated with levothyroxine prescription included higher TSH (4-10 mIU/L) at cohort entry (OR: 4.9, 95% CI: 4.5, 5.4), SCH diagnosis at prior pregnancy (OR: 1.9, 95% CI: 1.7, 2.1), SCH diagnosis during pregnancy but not in the year before (OR: 1.9, 95% CI: 1.7, 2.1), diabetes (OR: 1.7, 95% CI: 1.4, 2.1), and obesity (OR: 1.3, 95% CI: 1.1, 1.4).

Conclusions: Our study suggests that few women with SCH receive levothyroxine during pregnancy and the choice of whether to prescribe may be related to preexisting comorbidities and TSH.

3807 | trends in the use of pharmacologic treatments for pulmonary arterial hypertension from 2013-2017

Rob F Walker[1], Thenappan Thenappan[2], Kurt W Prins[2], Neil A Zakai[3], Joel F Farley[4], Richard F MacLehose[1], Alvaro Alonso[5], Pamela L Lutsey[1] and Pamela L Lutsey[1]

[1]University of Minnesota School of Public Health, Minneapolis, MN; [2]University of Minnesota Medical School, Minneapolis, MN; [3]University of Vermont, Burlington, VT; [4]University of Minnesota College of Pharmacy, Minneapolis, MN; [5]Emory University Rollins School of Public Health, Atlanta, GA

Background: Pulmonary arterial hypertension (PAH) is a rare but debilitating disease with a five-year mortality rate of approximately 40%. Since 2013, several new drugs have been approved by the U.S. Food and Drug Administration (FDA) to treat PAH, which act via vasodilation, platelet aggregation inhibition and/or antiproliferative effects on vascular smooth muscle cells. Trends in the adoption and use of PAH medications are not well documented.

Objectives: To estimate temporal trends in FDA-approved PAH prescription fills among PAH patients from 2013 through 2017 in the U.S.

Methods: MarketScan databases for years 2013 through 2017 were used to identify PAH cases using International Classification of Diseases (ICD) 9 and 10 codes 416.0 and I27.0, respectively. Prescriptions for PAH medications were identified via outpatient pharmaceutical claims data. PAH drugs were categorized into five classes: phosphodiesterase-5 inhibitors (PDE5i), endothelin receptor antagonists (ERAs), prostacyclin derivatives (PDs), guanylate cyclase stimulators (sGCs) or IP receptor agonists. Prescription fill counts for each category were assessed and aggregated into one year intervals to describe the temporal trends.

Results: We identified 30,729 individuals with PAH. Mean age of this population at date of PAH diagnosis was 64.5 years (SD: 20.2) and 62.7% were female. Of those with ICD codes for PAH, only 19.4% (n = 5,959) ever filled prescriptions for FDA approved PAH treatments. These patients received a cumulative 137,890 prescription fills. Patients who filled prescriptions for PAH medications tended to be younger in age (58.5 years, (SD: 19.0) and were 62.1% female. In 2013, 50.9% of prescriptions were for PDE5is and 43.2% for ERAs, while the remainder were prescribed PDs (5.7%) and sGCs (0.2%). By 2017, 44.1% were prescribed PDE5is and 36.8% PDE5s while percentages of those prescribed PDs, sGCs, and IP receptor agonists increased to 8.7%, 6.2%, and 4.2%, respectively.

Conclusions: PDE5i and ERA therapies make up the majority of prescriptions that PAH patients receive, though their use decreased moderately between 2013 and 2017. Recently approved treatment categories such as sGCs and IP receptor agonists were used with increasing frequency in recent years while PD prescription frequency has remained steady across time. With the shift towards prescribing new PAH treatments, opportunities exist to examine the comparative effectiveness and safety of new PAH therapies in real-world settings.

3832 | Prevalence and prescribing trends in bipolar disorder in Hong Kong from 2001-2018

Vanessa Ng[1], Kenneth Man[1,2], Le Gao[1], Esther Chan[1], Edwin Lee[3] and Ian Wong[1,2]

[1]Centre for Safe Medication Practice and Research, Department of Pharmacology and Pharmacy, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]UCL School of Pharmacy, London, United Kingdom; [3]Department of Psychiatry, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Bipolar disorder (BD) is a chronic mental disorder characterised by fluctuating manic and depressive episodes hence lifelong treatment is needed for mood stabilisation. The exact prevalence of BD and trend of local prescribing of treatment in Hong Kong are still unknown.

Objectives: To describe the prevalence and time trends of BD and the use of psychotropic medications in BD in Hong Kong from 2001-2018.

Methods: A population-based observational study was conducted using the electronic health records in Clinical Data Analysis and Reporting System (CDARS) authorised by Hong Kong Hospital Authority. Patients with BD aged ≥6 between 2001 to 2018 were identified using ICD-9-CM codes. Psychotropic medications including lithium, antipsychotics, antidepressants, and antiepileptics with mood stabilising properties: valproate, lamotrigine, carbamazepine were investigated. The annual prevalence of BD diagnosis and medications use were calculated in percentage with 95% confidence interval (CI) using Poisson method and stratified by age and gender. All analyses were performed by SAS version 9.4 (SAS Institute, Cary, NC, USA).

Results: A total of 17,247 individuals with BD were identified, of which 16,018 were prescribed at least one psychotropic medications from 2001 to 2018. The prevalence of BD increased by 3 times [from 0.071% (95% CI 0.069-0.073) in 2001 to 0.221% (95% CI 0.217-0.224) in 2018]. Overall, the prevalence of antipsychotics and antiepileptics increased by 52.4% [from 22.5% (95% CI 21.6-23.4) in 2001 to 74.9% (95% CI 73.4-76.4) in 2018] and 41.6% [from 10.4% (95% CI 9.86-11.1) in 2001 to 52.1% (95% CI 50.9-53.4) in 2018] respectively. Valproate has the greatest increase in usage (36.4%), followed by quetiapine (27.7%) and olanzapine (17.7%). By 2018, 39.5% of women of childbearing age were prescribed valproate. The prevalence of lithium increased from 8.93% (95% CI 8.36-9.54) in 2001 to 17.0% (95% CI 16.3-17.8) in 2009, then remained stable till 2018. The prevalence of antidepressants increased by 19.5% [from 7.25% (95% CI 6.73-7.80) in 2001 to 26.7% (95% CI 25.8-27.6) in 2018].

Conclusions: Lithium use as first line treatment for BD remained relatively constant. Prescribing of antipsychotics, antiepileptics and antidepressants in patients with BD increased from 2001 to 2018. Valproate has been frequently prescribed to women of childbearing age, against advice from international treatment guidelines. Further studies are needed to assess the comparative efficacy and safety of different psychotropic medications among patients with BD, and to investigate the reasons of over-prescribing valproate to women.

3838 | Trends in HbA1c thresholds for initiation of hypoglycaemic agents: Impact of changed guideline recommendations for older and/or frail patients with type 2 diabetes

Martina Ambroz[1], Sieta de Vries[1], Klaas Hoogenberg[2] and Petra Denig[1]

[1]*University Medical Center Groningen, Groningen, Netherlands;* [2]*Martini Ziekenhuis, Groningen, Netherlands*

Background: Since 2011, guidelines have recommended less strict glycated haemoglobin (HbA1c) thresholds in older and/or frail type 2 diabetes (T2D) patients than in younger and less frail patients for initiating hypoglycaemic agents.

Objectives: To assess 1) trends in HbA1c thresholds at initiation of a first hypoglycaemic agent in T2D patients and 2) the influence of age and frailty on these trends.

Methods: The Groningen Initiative to Analyze Type 2 diabetes Treatment (GIANTT) database was used, which includes primary care T2D patients from the north of the Netherlands. Patients who initiated hypoglycaemic agent between 2008 and 2013 and had an HbA1c measurement within 120 days before initiation were included. Treatment initiation was defined as a prescription of a non-insulin hypoglycaemic agent without such a prescription in 365 days before. The influence of calendar year (trend), age (<60 years; 60 - 69 years; 70 - 79 years; and reference group ≥80 years) or frailty (electronic frailty index (eFI); tertiles with the highest tertile as reference group) and the interaction between calendar year and age or frailty were assessed using multilevel linear regression analyses adjusted for confounders (e.g. sex, duration of diabetes, chronic medication, blood pressure).

Results: We included 3,800 patients. The mean HbA1c threshold at treatment initiation was 7.4% in 2008 to 2010, 7.1% in 2011, 7.2% in 2012 and 7.3% in 2013. This trend was significant (p=0.006). On average, patients aged <60 years, 60 - 69 years, 70 - 79 years and ≥80 years initiated treatment at 7.4%, 7.2%, 7.2% and 7.4%, respectively. No significant differences were observed (p values 0.895, 0.269 and 0.626 for each of the younger age groups, respectively). Frailty groups initiated hypoglycaemic treatment at similar HbA1c thresholds (7.3% in the lowest two tertiles and 7.2% in the highest tertile). Again, there were no significant differences between groups (p values 0.581 and 0.383 for the lowest and middle tertile, respectively). The interactions between calendar year and age and calendar year and frailty were not significant (p>0.05).

Conclusions: The HbA1c thresholds at initiation of hypoglycaemic agents decreased significantly over the years, particularly between 2010 and 2011. This trend was not influenced by the patients' age or frailty, which is in contrast with changed treatment recommendations from guidelines in the study period. Additional efforts may be needed to get personalized diabetes care implemented in practice.

3840 | Statin use and discontinuation in older Danes: A nationwide drug utilization study

Wade Thompson, Dorte Jarbøl, Jesper B. Nielsen, Peter Haastrup and Anton Pottegård

University of Southern Denmark, Odense, Denmark

Background: There is limited evidence on the clinical effects of statins in older persons. Therefore, characterizing statin use in this population is of interest.

Objectives: Explore statin use and discontinuation patterns in older Danes between 2011 and 2016 using data from Danish health registries.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We measured (1) monthly prevalence and (2) quarterly incidence of statin use, each according to sex, age, and primary versus secondary prevention, as well as (3) characteristics of new users, (4) total amount of statin redeemed, and (5) the proportion of long-term statin users (taking statins 5+ years) who discontinued therapy between 2014 and 2016. Finally, we determined (6) factors associated with discontinuation in long-term users, using logistic regression. The study population was all Danes age ≥70 years.

Results: The prevalence of statin use increased from 30% in 2011 to 33% in 2016. At the end of 2016, the prevalence was 23% in the primary prevention population and 56% in the secondary prevention population. The quarterly incidence fell from 11 per 1000 persons in early 2011 to 7 per 1000 persons in late 2016. For incident users, the proportion age ≥80 years dropped from 30% in 2011 to 25% in 2016, while the proportion initiating for primary prevention decreased slightly from 58% to 53%. Around 19% of long-term statin users discontinued therapy between 2014 and 2016. Increasing age was the strongest predictor of statin discontinuation, while use of cardiovascular medications decreased the odds of discontinuation.

Conclusions: Statin use continues to be common among older Danes, with approximately 1 in 3 Danes age ≥70 years taking statins in 2016. Between 2011 and 2016, the prevalence of statin use was relatively stable while the incidence fell slightly. The characteristics of incident users changed over the study period, with a lower proportion starting a statin for primary prevention or starting after age 80 by 2016.

3850 | Use of antipsychotics in Denmark 1997-2018: A nation-wide drug utilization study with focus on off-label use and associated diagnoses

Mikkel Højlund[1,2], Jacob H Andersen[1], Kjeld Andersen[3,4], Christoph U Correll[5,6] and Jesper Hallas[1]

[1]University of Southern Denmark, Odense, Denmark; [2]Mental Health Services Region of Southern Denmark, Aabenraa, Denmark; [3]University of Southern Denmark, Odense, Denmark; [4]Mental Health Services Region of Southern Denmark, Odense, Denmark; [5]The Zucker Hillside Hospital/ Zucker School of Medicine at Hofstra/Northwell, Glen Oaks, NY; [6]Charité Universitätsmedizin, Berlin, Germany

Background: Antipsychotics (APs) are primarily licensed for the treatment of schizophrenia, bipolar disorder, and insufficiently responding unipolar depression. Prior drug utilization studies have found considerable and increasing use of APs among other groups.

Objectives: To 1) describe current AP use and associated diagnoses in Denmark, and 2) characterize the subgroup of users without diagnoses labelled for AP treatment.

Methods: We conducted a nation-wide drug utilization study by identifying all AP users in Denmark from 1997 to 2018 in the Danish National Prescription Register. Information on hospital contacts, use of other medications, and health care utilization were obtained from the Danish National Patient Register, the Danish National Prescription Register, and the National Health Insurance Services Register. Possible indications for AP treatment were evaluated using an indication hierarchy: Severe mental illness, other mental disorders, neurological disorders, and cancers (e.g., palliative care). Time trends in prevalence of these groups were evaluated. Users without any of the diagnoses mentioned above were described regarding type and duration of AP therapy, other psychopharmacological treatment, medical comorbidities, and health care utilization.

Results: We identified 630,234 AP users between 1997 and 2018. In 2018, the number of AP users in Denmark was 127,632, of whom 12% had recorded diagnoses of severe mental illness, 21% of other mental illness, 3.5% of only neurological disorders, 2.5% of only cancer diagnoses, and the remaining 61% had none of these diagnoses. "Neurotic or stress-related disorders (ICD-10 F40-49)" was most commonly associated with incident use (8.5% of incident users), followed by unipolar depression (ICD-10 F32-33) (8.2%). The majority of users without psychiatric, neurological, or cancer diagnoses were treated with one AP (87%), most commonly quetiapine (50%), and redeeming either one (21%) or more than five AP prescriptions (41%). APs in this population were commonly co-prescribed with antidepressants (47% of users). In 2018, a general practitioner was the likely initiator of AP treatment in 67% of incident users, and only 15% of incident users were seen by a psychiatrist during 2018.

Conclusions: Most AP users in Denmark did not have psychotic disorders, and more than half of AP users have no psychiatric, neurological or cancer diagnosis. Health insurance data indicate that a considerable proportion of APs is prescribed in general practice. Reasons for and the risk-benefit ratio of such use require urgent study.

3870 | National variation and factors associated with the transition from first use to long-term opioid use for non-cancer pain

Meghna Jani, Belay Birlie-Yimer, Therese Sheppard, Mark Lunt and William Dixon

University of Manchester, Manchester, United Kingdom

Background: Prescribing behaviour has been described as a key driver of rising opioid prescriptions and long-term opioid use. However the effect of prescribers requires interpretation within context. No studies have investigated the extent to which regions, practices, prescribers, vary in opioid prescribing accounting for case-mix by considering this hierarchy together.

Objectives: (i) Quantify and identify risk factors for the transition from new-user to long-term opioid user (ii) Quantify variation of long-term use attributed to region, practice and prescriber, accounting for patient mix and chance variation.

Methods: A retrospective observational UK study between 2006-2017 using CPRD was conducted. Opioids new users, ≥18 years, without cancer were identified. Long-term opioid use was defined as ≥3 opioid prescriptions issued within a 90-day period from index date, or ≥1 opioid prescription lasting at least 90 days in the 1st year. A multi-level random-effects logistic regression model was used to examine the association of patient characteristics with the odds of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

becoming a long-term opioid user. To examine variation in opioid use amongst prescribers, GP practices and region after adjusting for patient case-mix, we used a nested random-effect structure. A 'high-risk' region, prescriber or practice was defined as those where the entire adjusted 95% CI lay above population average.

Results: 1,968,742 new opioid users were included; 14.6% patients transitioned to long-term use. In the fully adjusted model, factors associated with higher odds of long-term opioid use included high MME/day [OR 7.6 (95% CI 6.3, 9.2), older age [OR 4.4 (4.3, 4.5), deprivation [OR 1.5 (1.4, 1.6)], fibromyalgia [OR 1.8 (1.5, 2.2)], rheumatological conditions [OR 1.5 (1.4, 1.6)], major surgery [OR 1.1 (1.05, 1.13)]. The North-West, Yorkshire and South-West were found to be high-risk regions for long-term use. 103 practices (25.6%) and 540 prescribers (3.5%) were associated with a significantly higher risk of long-term use. The odds of becoming a long-term user for a patient belonging to these prescribers reached up to >3.5 times than the population average.

Conclusions: Prescribing factors, age, deprivation, fibromyalgia and rheumatological conditions were associated with highest odds of long-term opioid use. In the first UK study evaluating long-term prescribing with adjustment for case-mix, variation in regions and especially practices and prescribers were observed. Our findings support greater calls for action to reduce practice and prescriber variation by promoting safe practice in opioid prescribing.

3891 | Use of hormonal therapy before and after diagnosis of breast, endometrial and colon cancer

Lina Mørch[1], Charlotte Skovlund[1], Amani Meaidi[2], Christian Dehlendorff[1], Søren Friis[1], Irene Petersen[3] and Anne Katrine Duun-Henriksen[1]

[1]Danish Cancer Society Research Center, Copenhagen, Denmark; [2]Copenhagen University Hospital, Copenhagen, Denmark; [3]University College London, London, United Kingdom

Background: Hormonal therapy is known to increase the risk of some types of cancers, while reducing the risk of others. We anticipate that women with breast and endometrial cancer discontinue hormone therapy around time of diagnosis, while we do not expect discontinuation in women with cancers on which hormone therapy has a neutral or even a protective effect; such as for colon and rectal cancer. Vaginal estrogens are anticipated to have local effect, thus discontinuation is not expected to the same extend as with other types of hormone therapy

Objectives: To examine patterns of hormone therapy use before and after a diagnosis of breast, endometrial or colon cancer in Denmark.

Methods: From Danish nationwide registries, we identified all women aged 50 years or older at diagnosis of incident breast, endometrial and colon cancer during 2000-2016, and comparison cohorts of birth year-matched women without cancer. We calculated rates of hormone therapy as prescriptions/person-year and examined use in 6 months intervals from two years before to two years after diagnosis. Prescription rates were calculated for all types of hormone therapy and for vaginal estrogens separately.

Results: We identified 54,206 women with breast, 9,817 women with endometrial and 18,356 women with colon cancer. Among women with breast cancer, the rates of hormone therapy prescriptions declined from 0.97 [0.95-0.98] per person-year 2-1.5 years before diagnosis to 0.36 [0.35-0.36] prescriptions/person-year 1.5-2 years after diagnosis. During the same period, also rates of vaginal estrogen prescriptions declined from 0.53 [0.52-0.53] to 0.34 [0.33-0.35]. Similarly, among women with endometrial cancer, the rates of hormone therapy prescriptions declined (0.90 [0.87-0.92] vs 0.70 [0.67-0.73]), whereas the rates of vaginal estrogen prescriptions remained stable (0.57 [0.55-0.59] vs 0.65 [0.63-0.68]). Among women with colon cancer, a slight decline in use of hormone therapy (0.60 [0.58-0.61] vs 0.51 [0.50-0.53]) was seen, while use of vaginal estrogen was unchanged (0.45 [0.44-0.46] vs 0.44 [0.42-0.45]). The comparison cohorts exhibited approximately stable rates of hormone therapy and vaginal estrogen prescriptions in the period.

Conclusions: In accordance with expectations use of hormone therapy declined markedly after diagnoses of breast and endometrial cancer, however, surprisingly also slightly after colon cancer. Use of vaginal estrogen declined after a diagnosis of breast cancer, but not after diagnosis of endometrial cancer or colon cancer.

3898 | Racial/ethnic Disparities in Pharmacotherapy and Recurrence of Urinary Tract Infections Among Medicare Beneficiaries

Erline E. Martinez-Miller[1,2], Julia B. Ward[1,3], Brian R. Matlaga[4], Kevin C. Abbott[5], Tamara Bavendam[5], Ziya Kirkali[5], John Lim[1], Casey Pierce[1] and Lydia B. Feinstein[1,3]

[1]Social & Scientific Systems, Durham, NC; [2]University of Texas Southwestern Medical Center, Dallas, TX; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD

Background: Urinary tract infections (UTIs) are highly prevalent among older adults and increasingly difficult to treat with multidrug resistance on the rise. In the United States, racial/ethnic minorities have less access to quality healthcare. Yet little is known about racial/ethnic disparities in UTI burden or its medical management.

Objectives: We examined racial/ethnic disparities in prescribed medications and UTI recurrence among Medicare beneficiaries aged ≥65 years with a UTI diagnosis.

Methods: We used the Centers for Medicare & Medicaid Services (CMS) Medicare 5% Sample from 2007-2016 (N=63,533). UTI episodes were defined as an outpatient claim with a relevant diagnosis code followed by a pharmacy claim for an anti-infectious agent within 72 hours. Anti-infectious agents were categorized using American Hospital Formulary Service classes. We estimated prevalence and duration of UTI-relevant prescription fills and cumulative probability

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of recurrent UTI within 12 months of the initial episode. Analyses were conducted overall and by race/ethnicity.

Results: Race/ethnicity among beneficiaries with UTI was distributed as follows: non-Hispanic White (88%), non-Hispanic Black (7%), Asian (2%), Hispanic (2%), American Indian/Alaska Native (AI/AN; 1%), and Other (1%). Overall, the most commonly prescribed medications were quinolones (42%), urinary anti-infectives (18%), sulfonamides (15%), and cephalosporins (11%). Of these, quinolones and sulfonamides had the lowest cumulative probability of UTI recurrence (39% and 41%, respectively), and urinary anti-infectives and cephalosporins had the highest (47% and 48%, respectively). Quinolones were most commonly prescribed among Asians (51%) and least among AI/ANs (39%). Cephalosporins were most commonly prescribed among AI/ANs (15%) and least among Asians (9%). AI/ANs and Hispanics had the highest cumulative probability of UTI recurrence (46% and 41%, respectively), while Asians had the lowest (34%). Those with medication duration ≥7 days, longer than recommended by guidelines, had the highest cumulative probability of UTI recurrence (44%). Accordingly, Hispanics and AI/ANs were most commonly prescribed medications for ≥7 days (41% and 42%, respectively, vs. 38% overall).

Conclusions: We identified racial/ethnic disparities in UTI pharmacotherapy and recurrence among older adults in the United States, particularly among AI/ANs. Future studies should determine whether improper use of anti-infectious agents for UTI treatment contributes to high frequency of recurrence in understudied minority populations.

3906 | Utilization of antidepressants in Brazil: A study based on private and public consumption data

Lívia Teixeira de Mattos[1], Cláudia Du Bocage Santos-Pinto[2] and Claudia Garcia Serpa Osorio-de-Castro[1]

[1]*Sergio Arouca National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil;* [2]*Federal University of Mato Grosso do Sul, Campo Grande, Brazil*

Background: Disease burden in Brazil shows that mental health disorders, especially depression, are on the rise. Economic recession has generated impoverishment and austerity measures have impacted on government health expenditures.

Objectives: This study profiles private and public consumption and expenditures of antidepressants considering context of recession and austerity in Brazil.

Methods: In a time-series analysis, from 2011 to 2017, public and private drug purchase data were used as *proxi* for consumption. Ten commonly prescribed antidepressants were selected, based on evidence for treatment of major depression, recommendation by national and international organizations and availability for retail and for government purchases, which were obtained from Brazilian Health Regulatory Agency SNGPC database for controlled substances and from the Federal SIASG database respectively. Socioeconomic and fiscal data were obtained from the Brazilian Institute for Geography and Statistics (IBGE) and from the Brazilian Central Bank. The ATC/DDD system standardized medicines and consumption output, in DDDs /1000 inhab per year. Linear regression and the Prais-Winsten technique for correction of autocorrelation were used for trend analysis.

Results: Time series showed variation in consumption and expenditures. Private and public consumption, and public expenditures, were expressed in tiers, according to range of DDDs/1000 inhab per year and of BRL per year, respectively. Results showed downward or constant trends for public purchases and rise in private purchases of all antidepressants, with marked decrease in GDP variation. Fluoxetine was the top drug in consumption from retail and government purchases, although trend was downward for public purchases and upward for retail.

Conclusions: Rising out-of-pocket expenditures for depression and decreasing government purchases reflect budget health cuts, possibly herding users to the private sector for their medicines. Increased antidepressant use may reflect disease burden as well as despondency and disenfranchisement in Brazil.

4024 | A population-based cohort study on the associations between selective serotonin reuptake inhibitor use before, during, and after pregnancy using data from the health improvement network

Jet WT Scheffers[1] and Irene Petersen[2,3]

[1]*Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands;* [2]*University College London, London, United Kingdom*[3]*Aarhus University, Aarhus, Denmark*

Background: Although depression is common in pregnancy, some women discontinue selective serotonin reuptake inhibitor (SSRI) treatment before or during pregnancy for various reasons. Limited information is available on how many of these women restart SSRI therapy after pregnancy.

Objectives: To examine the associations between selective serotonin reuptake inhibitor (SSRI) use in women before, during, and after pregnancy. In addition, we studied the effects of age and social deprivation on these associations.

Methods: We conducted a retrospective cohort study using data from The Health Improvement Network (THIN) UK primary care database. Women who had given live birth between 1 January 2000 and 31 December 2016 were identified and one random pregnancy was selected per woman. We estimated the number of women who were prescribed SSRIs in the 18 to 6 months before start of pregnancy, during pregnancy, and in the 12 months after delivery. We used Poisson regression to estimate risk ratios (RRs) of receiving SSRIs during pregnancy and after birth given prior treatment. Then, we studied the effects of social deprivation and age on the calculated RRs.

Results: In total, 210,603 pregnancies were included in this study. Of the 19,332 women who received a prescription for an SSRI before pregnancy, 2,840 (14.7%) were also prescribed SSRIs in the second trimester, while 9,630 (49.8%) received an SSRI in the year after delivery. Previously exposed women were 5.34 (95% confidence interval

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(CI), 5.24, 5.45) times more likely to receive postnatal SSRI treatment compared to women not on SSRIs before pregnancy. There was a strong effect of age and social deprivation on the risk of receiving SSRIs after delivery among women who were not exposed to SSRIs before pregnancy. Women below 20 years of age were 2.4 times (95% CI, 2.27, 2.56) more likely to receive SSRIs after delivery than women aged 30 or over. Moreover, women from the most deprived Townsend quintile were almost twice as likely as women from the least deprived quintile to receive a prescription for an SSRI after pregnancy.

Conclusions: While there is a strong association between SSRI treatment before pregnancy and after delivery, only half of the women treated before pregnancy received prescriptions for SSRIs in the year after delivery. These findings suggest that postnatal SSRI treatment is not just a continuum of previous episodes of SSRI treatment. More research is needed to determine the reasons why women stop AD therapy before or during pregnancy, and to identify women in need of postnatal treatment.

4029 | Methodological considerations and learnings from setting up the SABINA program

Cassandra Nan[1], Sofie Arnetorp[1], Maarten JHI Beekman[2], Niklas Lindarck[3], Jennifer K. Quint[4] and Claudia S. Cabrera[1]

[1]AstraZeneca, Gothenburg, Sweden; [2]AstraZeneca, The Hague, Netherlands; [3]AstraZeneca, Södertälje, Sweden; [4]Imperial College London, London, United Kingdom

Background: Recent international asthma management guidance recommends the addition of inhaled corticosteroids to short-acting β_2-agonists (SABAs) to address the underlying inflammation of asthma. The SABA use IN Asthma (SABINA) program describes SABA use globally using primary and secondary data collection methods.

Objectives: To describe methodological considerations and learnings from designing the SABINA program across countries with different healthcare systems and data availability.

Methods: A core protocol (SABINA I) was developed for the Clinical Practice Research Datalink (CPRD), a UK primary healthcare database. Two umbrella protocols were developed based on the core one: a distributed protocol for 8 countries where medical records, pharmacy dispensing databases, or patient registries were available (SABINA II), and a cross-sectional primary data collection protocol for 25 countries with no national healthcare databases (SABINA III). Key definitions (e.g., asthma severity, SABA use), inclusion criteria, and core tables were standardized to maximize between-country comparisons. Protocols were developed in collaboration with local investigators and clinical experts to ensure appropriate study implementation and applicability of results.

Results: Five countries across SABINA I and II have completed analyses comprising >1 million patients, while data has been collected for >8500 patients in SABINA III. Available results from studies with varying levels of complexity show consistent SABA use patterns and its consequences, despite different data sources, healthcare and reimbursement policies. Developing an umbrella distributed program with a tailored framework, including standard definitions, tables, and adaptable algorithms, required several iterations to achieve as data in each country were progressively better understood.

Conclusions: Early involvement of knowledgeable collaborators is key for the efficient development of a large program across multiple healthcare settings and countries to ensure clarity of study objectives and specific country needs. Development of a lexicon for use across countries could help minimize variability in regional terminologies. Granularity of data in the CPRD is rare in most other countries. Although initial feasibility assessments might have facilitated more sophisticated clustering of cross-country results, the step-wise approach of adapting the CPRD protocol to other countries ensured scientific robustness and a point of reference for individual studies within SABINA, maximizing the use of the included databases for this and future studies in asthma.

4036 | Trends in benzodiazepine utilization in Romania during 1998-2018

Irina Cazacu[1], Anamaria Cristina[1], Andreea Maria Farcaş-Călugăr[2], Sinziana Gheorghe-Cetean[3], Cristina Pop[1], Irina Brumboiu[4] and Cristina Mogosan[1]

[1]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania; [3]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania; [4]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania

Background: Increasing concerns on benzodiazepine (BZD) utilization regarding the misuse, dependence, tolerance and difficulty in treatment discontinuation highlight the importance of conducting drug utilization studies in Romania, data on BZDs utilization being scarce.

Objectives: To examine 20-year trends (1998-2018) of BZDs utilization (for all pharmaceutical forms and all indications) in Romania using WHO Defined Daily Doses (DDD).

Methods: We analyzed estimated data from Pharma & Hospital Report CEGEDIM study during 1998-2018, which includes primary data from a panel of retail and hospital pharmacies in Romania. The results are presented in DDD/1000people/day for each BZD International Nonproprietary Name (INN) and in total.

Results: Global BZD utilization increased by 10.8% from 1998 to 2018 (13.8 to 15.3 DDD/1000people/day). We observed major increases in alprazolam (0.2 to 5.5) and lorazepam (0.1 to 3.5) during the same time. The most used BZD in the 20-year period was diazepam (39.0%), followed by alprazolam (22.7%), nitrazepam (11.5%) and medazepam (6.8%). Between 1998 and 2003, we noticed an overall 24.6% decrease in BZDs utilization in Romania, driven by a fall in diazepam utilization (42.1% decrease), and important reductions in oxazepam (decrease by 91.0%), chlordiazepoxide (79.6%) and flunitrazepam

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(78.6%) use, the last three losing their market availability starting 2005. Diazepam, despite an increase in utilization by 30.6% in 2004 compared to 2003, had a steady decrease during 2005-2018, from 6.4 in 2005 down to 3.1 DDD/1000people/day in 2018. Simultaneously, alprazolam and lorazepam had steady increases, from 2.7 and 0.3 in 2005 reaching 5.5 and 3.5 respectively in 2018. Consumption of nitrazepam remained almost static during 1998-2018 (on average 1.5), while for medazepam it decreased from 2.1 in 1998 to 0.2 in 2018, and for bromazepam more than tripled, from 0.3 to 1.0.

Conclusions: Romania faced an increasing use of BZDs during 1998-2018. Even if consumption of diazepam and medazepam decreased during this time, other BZDs gained popularity (alprazolam, lorazepam, and bromazepam). These variations in BZDs use could have been influenced by multiple factors: the release of the modern hypnotics (e.g. zolpidem) which gained popularity starting 2003 in Romania, the ageing population, which largely uses BZDs, the market withdrawal of some BZDs (flunitrazepam, oxazepam, chlordiazepoxide) in Romania, the changes in the national drug reimbursement list or the increased awareness of anxiety disorders and their treatment, mainly involving BZDs.

4037 | Use of analgesics among breast cancer patients in Denmark: A nationwide cohort study

Charlotte Skriver[1], Anne Katrine Duun-Henriksen[1], Irene Petersen[2,3], Christian Dehlendorff[1] and Søren Friis[1,3,4]

[1]Danish Cancer Society, Copenhagen, Denmark; [2]University College London, London, United Kingdom; [3]Aarhus University Hospital, Aarhus, Denmark; [4]University of Copenhagen, Copenhagen, Denmark

Background: An increasing number of breast cancer (BC) patients survive their disease, but some patients may experience chronic pain due to sequela of cancer disease and/or treatment.

Objectives: To examine the use of analgesic drugs among BC patients compared with women from the general population in Denmark.

Methods: We conducted a population-based cohort study using Danish nationwide cancer, prescription, and demographic registries. We identified all Danish women aged ≥30 years with a primary diagnosis of localized BC during 2000-2015. For each BC patient, we randomly selected five women of similar age from the general population who were alive and without cancer history at diagnosis of the corresponding patient (index date). BC patients and comparison women were followed from index date until date of cancer diagnosis (second cancer diagnosis for BC patients), emigration, death, or end of follow-up on 31 December 2016. We assessed use of opioids, nonsteroidal anti-inflammatory drugs (NSAIDs), and paracetamol among BC patients and comparison women by estimating prescription rates with 95% confidence intervals (CIs) for each drug group within three prespecified time intervals of 0-5, 5-10, and 10-15 years postdiagnosis. In Denmark, opioids are available on prescription only, whereas some NSAIDs (aspirin and low-dose ibuprofen) and paracetamol are also available over the counter.

Results: We identified 33,991 BC patients and 157,523 comparison women (mean age at index date, 64 years). Median follow-up from index date was 6.3 years (interquartile range: 3.3-10.0 years). The prescription rate for opioids was higher among BC patients than among comparison women within 0-5 years after diagnosis (1.26 [95% CI: 1.26-1.27] vs. 1.06 [95% CI: 1.05-1.06] prescriptions/person-year) and remained higher 5-10 years (1.38 [95% CI: 1.37-1.39] vs. 1.15 [95% CI: 1.15-1.16]) and 10-15 years (1.35 [95% CI 1.33-1.36] vs. 1.20 [95% CI: 1.19-1.20]) after BC diagnosis. Among long-term BC survivors, the higher use of opioids was solely seen for strong opioids (10-15 years: 0.55 [95% CI: 0.54-0.56] vs. 0.42 [95% CI: 0.41-0.42] prescriptions/person-year). For NSAIDs and paracetamol, no major differences in prescribing rates were seen between BC patients and comparison women.

Conclusions: Women with localized BC had persistently higher use of opioids during 15 years after diagnosis compared with women in the general population. Our finding of higher use of strong opioids more than 10 years after BC diagnosis indicates that some women surviving BC suffer from severe long-term pain related to the disease or its management.

4066 | Substantial differences in the anticholinergic burden across sex and age groups in a large population-based sample

Jonas Reinold[1], Oliver Riedel[1] and Ulrike Haug[1,2]

[1]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany[2]University of Bremen, Bremen, Germany

Background: Several drugs used to treat diseases such as depression, cardiovascular diseases, asthma, and COPD inhibit the effect of acetylcholine. Given that the cumulative effect of anticholinergic medications (also called anticholinergic burden) can lead to functional and cognitive decline, falls, and death, monitoring the anticholinergic burden is of high public health relevance. However, large comprehensive studies on the anticholinergic burden are scarce.

Objectives: To provide a detailed description of the anticholinergic burden by age and sex in a large population sample.

Methods: We used the German Pharmacoepidemiological Research Database (GePaRD) with health insurance claims data from ~17% of the German population. We included persons with ≥1 day of insurance coverage in 2016 preceded by ≥1 year of continuous enrollment and excluded persons hospitalized for ≥3 months in 2016. Based on outpatient drug dispensations in 2016 and the Anticholinergic Cognitive Burden (ACB) scale, we classified persons into four categories: no (ACB=0), low (ACB=1), intermediate (ACB=2), and high (ACB≥3) anticholinergic burden. We also determined the cumulative ACB score as continuous variable.

Results: Among 16,470,946 persons (54% female), the prevalence of ACB≥3 was 832 per 10,000 in women and thus 48% higher compared to men (564 per 10,000). In women, the prevalence of ACB≥3 was highest in the age groups 50-59 (1,087 per 10,000) and 70-79 (1021 per 10,000), while in men it was highest among those <18 (543 per

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

10,000) and in the age group 70-79 years (501 per 10,000). Regarding ACB-relevant medication, we focused on persons in each age and sex group whose cumulative ACB score was in the upper quartile. Among these persons, ACB-relevant medications were mainly prescribed by general practitioners with differences across sex and age groups regarding the type of ACB-relevant medication. For example, in women aged 35-49, the main contributors to the ACB were antidepressants (46%) and antipsychotics (25%) compared to medication for urinary incontinence and overactive bladder (27%), antidepressants (24%), and cardiovascular medication (23%) in women aged 65-79.

Conclusions: This comprehensive overview showed that a high anticholinergic burden is common in the German general population, particularly in vulnerable age groups. Given that the ACB-relevant medication substantially differs between age and sex groups, targeted interventions at the prescriber level are needed to increase awareness of this topic, as well as further studies on potential risks of a high ACB in specific subgroups.

4087 | Trends in the use of disease-modifying therapies among reproductive-aged women with multiple sclerosis in the United States 2001-2017

Emilie D Duchesneau[1], Michele Jonsson Funk[1], Alan C. Kinlaw[2] and Jennifer L Lund[1]

[1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC

Background: Multiple sclerosis (MS) is a chronic disease of the central nervous system. MS preferentially affects women and typical disease onset occurs during reproductive years. Orally administered disease-modifying therapies (DMTs) were first FDA-approved for MS in 2010, but no DMTs of any kind have been approved for MS treatment during pregnancy.

Objectives: To describe the monthly prevalence of DMT use among commercially-insured, reproductive-aged women from 2001-2017.

Methods: This study used the IBM Watson Health MarketScan Commercial Claims and Encounters data from 2000-2017. The population of interest (denominator) included all women age 12-45 years with ≥12 months of continuous enrollment and ≥1 inpatient or ≥2 outpatient diagnosis codes for MS during the 12 months prior to the index month. The monthly prevalence of DMT use was calculated separately for each injectable/infused DMT (glatiramer acetate [GA]; interferon [IFN] β-1a; IFNβ-1b; pegIFNβ-1a; and natalizumab) and each oral DMT (dimethyl fumarate; fingolimod; and teriflunomide). DMTs were identified using National Drug Codes in outpatient prescription claims and Healthcare Common Procedural Coding System codes in the inpatient or outpatient services files. The numerator included women meeting the denominator criteria with any days supply of DMTs overlapping with the index month. Monthly prevalence was standardized by age and region.

Results: The number of reproductive-aged women with MS in the population of interest ranged from 467-9847 across months of the study period and peaked in 2012. The mean age was stable over time at 37 years. Each month, 40%-60% of reproductive-aged women with MS received at least one DMT. IFNβ-1a was the most common before 2010, with a peak prevalence of 31% in 2001, declining thereafter. GA prevalence increased from 10% in 2001 to 20% in 2010; GA use decreased after 2010 but remained second-most common during 2014-2017. After 2010, use of fingolimod and dimethyl fumarate increased drastically, with fingolimod prevalence peaking at 11% in 2016. Dimethyl fumarate was the most common DMT in 2014-2017, with prevalence ranging from 13-17%. Prevalence of natalizumab increased steadily after its FDA approval in 2004, plateauing at ~8% in 2012. Use of pegIFNβ-1a and teriflunomide was low in all years (<3% each).

Conclusions: Use of oral and injectable/infused DMTs in reproductive-aged women with MS is high. Additional research is needed on the safety of DMTs during pregnancy, particularly for DMTs such as dimethyl fumarate, GA, and fingolimod, which have been highly utilized in recent years.

4098 | Controlled drug prescribing of opioids by private prescribers in England, 2014-2018

Georgia C. Richards[1], Helen J. Curtis[2], Brian MacKenna[2], Alex Walker[2] and Ben Goldacre[2]

[1]University of Oxford, Oxford, United Kingdom[2]University of Oxford, Oxford, United Kingdom

Background: The prescribing of opioids has increased by 127% since 1998 in England. To date, most research on opioids has focused on prescriptions dispensed in the public sector. Little is known about the volume of opioids being prescribed privately.

Objectives: We aim to assess the trend of controlled drug prescriptions for opioids dispensed by private prescribers in England between 2014 and 2018.

Methods: We conducted a retrospective observational study. We obtained private prescription data through a freedom of information (FOI) request to the NHS Business Services Authority (BSA). The data was provided as summarised items for Schedule 2 and Schedule 3 controlled drugs dispensed privately at the area team level for drugs with a British National Formulary (BNF) chemical substance code of 4.7.2 (i.e. opioid analgesics) and 4.10.3 (i.e. opioid dependence) in quarterly splits from January 2014 to December 2018. We calculated the number of controlled opioid items dispensed for each calendar year (in crude terms) and determined the percentage change from 2014 to 2018. We stratified the data by the type of opioid using the BNF chemical substance codes to calculate the number of items for each opioid in each calendar year. We calculated the average number of items dispensed for each type of opioid over five years and ranked the opioids from most to least dispensed. We did not standardise the items dispensed by population data as the proportion of the English population who obtain medicines from prescribers registered with private prescriber codes is not publically available.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Controlled opioids dispensed privately decreased by 46% since 2014 (from 23,339 items in 2014 to 12,724 items in 2018). Methadone (7,772 items per year) was the most commonly dispensed controlled opioid followed by morphine (3,444 items per year), buprenorphine (2,637 items per year), tramadol (2,045 items per year) and oxycodone (1,812 items per year).

Conclusions: This is the first analysis of controlled opioids dispensed privately in England. Our findings indicate that the trend is decreasing. Opioids predominately used for the treatment of dependence (i.e. methadone and buprenorphine) are commonly dispensed by private prescribers in England.

4099 | Psychotropic medications utilization in adult cancer patients in China: Based on National Health Insurance database

Lin Bai[1], Cong Huang[1], Haishaerjiang Wushouer[2,3,4], Ziyue Xu[1], Xiaodong Guan[1,4] and Luwen Shi[1,4]

[1]Department of Pharmacy Administration and Clinical Pharmacy, School of Pharmaceutical Sciences, Peking University, Beijing, China; [2]Center for Strategic Studies, Chinese Academy of Engineering, Beijing, China; [3]School of Medicine, Tsinghua University, Beijing, China; [4]International Research Center for Medicinal Administration, Peking University, Beijing, China

Background: Psychotropic medications are useful to treat psychiatric disorders which are frequently underdiagnosed and undertreated in cancer patients. The evidence on utilization of psychotropic medications in cancer patients was absent in China.

Objectives: To determine the prescription rates and types of psychotropic medications in cancer patients in China.

Methods: We used the data from China Health Insurance Association database in 2015-2017, which contained health care utilization data for a national representative sample of basic medical insurance beneficiaries. Cancer patients aged 18 and over were identified by International Classification of Disease 10th revision (ICD-10) code C00-C97. We calculated the prescription rates of psychotropic medications in cancer patients. Outcomes were compared by demographics and clinical variables, using Chi-square test.

Results: A total of 260,364 adults with cancer were identified in the database, of which 19.1% were prescribed at least one psychotropic medication, comprising hypnotics and sedatives (11.0%), anxiolytics (9.8%), antipsychotics (1.4%), antidepressants (0.9%) and mood stabilizers (0.7%). Among sample patients prescribed psychotropic medications, the most commonly prescribed were midazolam (43.8%), diazepam (23.9%) and estazolam (22.5%). The 31.7% of the cancer patients with psychotropic medications were on more than one psychotropic medication, and 2.4% were on more than three. The prescription rate of psychotropic medications in cancer patients decreased significantly from 2015 to 2017 (20.6% vs. 18.0%, P<0.001). Cancer patients covered by the Urban Employee Basic Medical Insurance were more likely to use psychotropic medications than those covered by the Urban Rural Resident Basic Medical Insurance (19.5% vs. 18.1%, P<0.001). Cancer patients in Eastern regions were more likely to use psychotropic medications than those in Western regions (28.8% vs. 10.7%, P<0.001). The prescription rate of psychotropic medications in patients with malignant neoplasms of eye, brain and other parts of central nervous system (ICD-10 code C69-C72) (35.0%) was the highest among sample patients. Patients with malignant neoplasms of mesothelial and soft tissue (ICD-10 code C45-C49) (10.8%) and malignant neoplasms of ill-defined, secondary and unspecified sites (7.1%) had the lowest prescription rate.

Conclusions: The prescription rates of psychotropic medications in Chinese adult cancer patients were still low. The appropriate use of psychotropic medications in cancer patients needed to be further addressed in China.

4113 | Infection-related hospitalisations after common infections are associated with antibiotic prescribing in primary care

Birgitta van Bodegraven[1], Victoria Palin[1], Chirag Mistry[1], Matthew Sperrin[1], Andrew White[2], William Welfare[3], Darren M. Ashcroft[4] and Tjeerd P. van Staa[1]

[1]The University of Manchester, Manchester, United Kingdom; [2]NHS Greater Manchester Shared Service, Oldham, United Kingdom; [3]Public Health England North West, Manchester, United Kingdom; [4]The University of Manchester, Manchester, United Kingdom

Background: Research on antimicrobial resistance (AMR) and antibiotic prescribing often focus on reducing inappropriate prescribing. There is doubt with regards to the link between antibiotic prescribing levels and complications that can arise after common infections.

Objectives: Determine the association of incident antibiotic prescribing levels for common infections with infection-related complications and hospitalisations by comparing high with low prescribing GP practices.

Methods: This was a retrospective cohort study using UK primary care records from the Clinical Practice Research Datalink (CPRD GOLD) and SAIL Databank (SAIL) linked with Hospital Episode Statistics (HES) data. These databases hold anonymised patient-level electronic health records. 546 CPRD practices, 346 CPRD-HES linked and 338 SAIL-HES practices were included. Patients had a GP consultation and clinical READ code for a common infection. This was the first consultation for common infection in 6 months and without an antibiotic prescription in the previous 1 month. Six common infections were included: upper respiratory tract infection (URTI), lower respiratory tract infection (LRTI), otitis externa, otitis media, sinusitis, and urinary tract infection (UTI). Two outcomes were included in the analysis: infection-related hospital admission and infection-related complication as recorded in primary care records. Outcomes were evaluated for 30 days after the consultation. Negative binomial regression was used to model the rate of complications. All variables were scaled with their interquartile range (IQR: 75th to 25th percentile) to create a comparison between high and low prescribing practices.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A 10.4% higher antibiotic prescribing rate (IQR) was associated with an IRR of 0. 943 (0.920 to 0.967), meaning a 5.7% lower infection-related hospital admission rate. The observed association varied by infection. The largest difference in the incidence of hospital admission was observed in LRTI (IRR: 0.839; 16.1%; 95%CI: 12.4% to 19.7%), UTI (IRR: 0.853; 14.7%; 95%CI: 7.6% to 21.1%), and URTI (IRR: 0.935; 6.5%; 95%CI: 3.5% to 9.5%). The association of antibiotic prescribing levels and hospital admission was largest in younger patients (6.0%; 1.6% to 10.1%).

Conclusions: Higher levels of incident antibiotic prescribing by GP practices were associated with lower risk of hospital admission and GP diagnosed infection-related complications. Indiscriminately reducing antibiotic prescribing may lead to harm. Greater focus is needed to optimise antibiotics to patients most likely to benefit.

4127 | Self-reported misuse of oral tramadol in the U.S.A.: Analysis of the National Survey on Drug Use and Health (NSDUH), 2002-2017

Thomas Rhodes[1], Sydney T. Thai[2,1], Molly Aldridge[1], Suzanne F. Cook[1] and Cynthia J. Girman[1]

[1]CERobs Consulting, LLC, Wilmington, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Oral tramadol, a weak opioid, was approved in the USA in 1995 and designated a Schedule IV drug in 2014. Population-based estimates of oral tramadol misuse are limited.

Objectives: Describe self-reported misuse of oral tramadol and comparator oral opioids.

Methods: NSDUH is an annual, cross-sectional, population-based survey of self-reported alcohol, drug, and tobacco use among non-institutionalized persons (≥12 years old). NSDUH was used to assess misuse of oral tramadol and oral analgesics containing tramadol. Misuse is defined as use of a drug "in any way a doctor did not direct [the respondent] to use it". Lifetime (ever) misuse (2002-2014) or past-year misuse (2015-2017) for oral tramadol were self-reported. Misuse of morphine, oxycodone, and hydrocodone was also assessed. Counts were weighted to approximate the USA population and reported as a percent. Analyses were stratified by demographics and by responders who report misuse of oral tramadol alone versus those who also misuse comparators. Prescription volume data (Symphony Health Solutions, PRA Health Sciences) were used to estimate misuse per units dispensed (prescriptions or pills) to estimate public health impact.

Results: For 2002-2014, lifetime misuse (as a % of USA population) of oral tramadol and morphine remained <2%; reported misuse increased over time corresponding to increased media attention on abuse of more potent opioids. Lifetime misuse ranged from 4-10% for hydrocodone and oxycodone. For 2015-2017, 0.6-0.7% of the study population reported past-year misuse of oral tramadol. Past-year misuse of oral tramadol was higher in females, predominately in young-to-middle-aged adults, and was often in combination with other opioids. Past-year misuse of morphine, oxycodone, and hydrocodone was reported by 0.2-0.3%, 1.4-1.6%, and 2.3-2.7% of respondents, respectively. Among all self-reported users of oral tramadol, 9-10% reported past-year misuse of tramadol compared to past-year misuse of comparator opioids among self-reported users of morphine (8-9%), hydrocodone (12-13%), and oxycodone (14-15%). Based on dispensing data, the frequency of past-year misuse was lower for tramadol (41-46 cases/1,000 prescriptions; 5-6 cases/10,000 pills) compared to comparator opioids (68-84 cases/1,000 prescriptions; 10-12 cases/10,000 pills).

Conclusions: Among non-institutionalized USA residents, the prevalence of self-reported oral tramadol misuse is low relative to other opioids. Based on dispensing data, the frequency of past-year misuse was lower for oral tramadol relative to comparator oral opioids.

4141 | Hormonal contraception before and after a breast cancer diagnosis

Charlotte Skovlund[1], Anne Katrine Duun-Henriksen[1], Christian Dehlendorff[1], Søren Friis[1], Irene Petersen[2] and Lina Mørch[1]

[1]Danish Cancer Society, Copenhagen, Denmark; [2]University College London, London, United Kingdom

Background: Use of hormonal contraception is known to slightly increase the risk of breast cancer, while it remains unclear if hormonal contraception use influences survival after breast cancer. Recently, use of hormonal intrauterine devices (IUD) was found to increase the risk of breast cancer. It is known that use of oral contraceptives decreases after a diagnosis of breast cancer, however, we do not know if use of hormonal IUD decreases.

Objectives: To examine patterns in use of hormonal contraception, including IUD, before and after a diagnosis of breast cancer in Denmark.

Methods: From the Danish Cancer Registry, we identified 11,865 women aged 13-49 years with incident breast cancer during 2000-2016. The women with an incident breast cancer in this period were matched on birth year to women without cancer (n=52109). Eligible control women had to be alive and cancer free on the date of diagnosis of the corresponding breast cancer woman. Prescriptions of hormonal contraception were identified in the Danish Prescription Registry and divided into two groups: hormonal IUD and other hormonal contraception. Prescription rates per person-year were calculated from 2-0 years before and 0-2 years after the cancer diagnosis in intervals of 3 months.

Results: For hormonal contraceptives overall, there was a rapid decline in prescription rates after breast cancer diagnosis. The prescription rates of hormonal IUD were similar among women with breast cancer and women without cancer before the diagnosis, i.e., 0.02 prescriptions [0.02-0.03] per person-year for women with breast cancer and 0.02 [0.02-0.02] for women without cancer). After breast cancer diagnosis the prescription rate declined to 0.01 [0.00-0.01]/person-year for hormone IUD, while it was unchanged for women without cancer. The prescription rate for other hormonal contraception products was slightly higher before the diagnosis of breast

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cancer (0.70 [0.69-0.71]) compared to women without breast cancer (0.57 [0.56-0.57]). After the breast cancer diagnosis there was a rapid decline in the prescription rate to 0.05 [0.05-0.05].

Conclusions: Prescription rates of hormonal intrauterine devices (IUD) and other hormonal contraception products declined rapidly after a breast cancer diagnosis and remained low two years after the diagnosis.

4148 | Utilisation of oral anticoagulants for stroke prevention in older people in the UK

Anneka Mitchell[1,2], Margaret C. Watson[3], Tomas J. Welsh[4,5,6], Julia Snowball[1] and Anita McGrogan[1]

[1]University of Bath, Bath, United Kingdom; [2]University Hospital Southampton, Southampton, United Kingdom; [3]University of Strathclyde, Glasgow, United Kingdom; [4]Research Institute for the Care of Older People (RICE), Bath, United Kingdom; [5]University of Bristol, Bristol, United Kingdom; [6]Royal United Hospitals, Bath, United Kingdom

Background: International guidelines recommend that oral anticoagulants (OACs) are prescribed to patients with atrial fibrillation (AF) who have additional risk factors for stroke. Advancing age is a significant risk factor and most guidelines recommend that OACs are considered for all patients ≥75 years. Historically, OACs have been underused in this group; it is not known how the introduction of direct OACs have affected overall OAC prescribing to older adults.

Objectives: To evaluate the effect of age and comorbidities on OAC prescribing to older individuals with AF.

Methods: A cohort of patients was identified in the Clinical Practice Research Datalink (CPRD). The study period was 1/1/2013-27/12/17 as DOACs and warfarin were available. To enter the cohort, patients needed: 1 year of research standard data, a diagnosis of AF, ≥75 years, and a year free of OAC prescribing before entering. Comorbidities for evaluation were selected *a priori* based on clinical factors likely to affect OAC use. Multivariate logistic regression was used to determine adjusted odds ratios of being prescribed an OAC.

Results: There were 43 984 people in the cohort, 45.4% were newly started on an OAC during the study. In the multivariate analysis, the odds of being prescribed an OAC were strongly influenced by advancing age OR = 0.85 (95% CI 0.80-0.89) in 80-84 years, OR 0.56 (95% CI 0.53 - 0.59) in 85-89 years, OR = 0.20 (95% CI 0.19-0.22) in ≥90 years compared with those aged 75-84 years. Comorbidities associated with a significant decrease in the odds of receiving an OAC were dementia (OR 0.26, 95% CI 0.24-0.29); falls compared with no falls (1-2 falls OR 0.74, 95% CI 0.69-0.79; 3+ falls OR 0.53 95% CI 0.43-0.64); previous fracture (OR 0.82, 95% CI 0.78-0.87); acute kidney injury (OR 0.71, 95% CI 0.63-0.80); chronic renal impairment (OR 0.92, 95% CI 0.88-0.96); liver disease (OR 0.68, 95% CI 0.57-0.82). A history of intracranial (OR 0.32, 95% CI 0.27-0.39) or gastrointestinal bleeding (OR 0.85, 95% CI 0.80-0.90) decreased OAC prescribing. Comorbidities associated with an increase in the likelihood of receiving an OAC were hypertension (OR 1.37, 95% CI 1.31-1.43) or history of stroke or transient ischaemic attack (OR 1.39, 95% CI 1.31-1.46).

Conclusions: OACs are underused in older people, with use declining with age. Fear of bleeding is commonly cited as a reason for under use of OACs in this group, however the association remained after adjusting for comorbidities. A history of falls decreased the odds of receiving an OAC, there is little evidence to support the link between falls and bleeding risk and UK guidelines specifically state that OACs should not be withheld due to falls risk.

4153 | Identifying cohorts of patients with type2 diabetes mellitus initiating dapagliflozin in three data sources

J. Bradley Layton[1], Cindy K. Zhou[2], Heather E. Danysh[3], Daniel C. Beachler[2], Ryan Ziemiecki[1], Jade Dinh[2], Ruihua Yin[2], Brian Calingaert[1], Phillip R. Hunt[4], Alicia W. Gilsenan[1] and Catherine B. Johannes[3]

[1]RTI Health Solutions, Research Triangle Park, NC; [2]HealthCore, Wilmington, DE; [3]RTI Health Solutions, Waltham, MA; [4]AstraZeneca, Gaithersburg, MD

Background: A multi-database study of dapagliflozin, a sodium-glucose cotransporter 2 inhibitor, utilized United Kingdom- and United States (US)-based data sources to identify historical cohorts of patients with type 2 diabetes mellitus (T2DM) initiating dapagliflozin. While the data sources differ in patient populations, data systems, and health care delivery and practice, a common protocol and statistical analysis plan were applied with data source-specific adaptations.

Objectives: To describe differences in patient characteristics and initiation patterns among new users of dapagliflozin with T2DM in three data sources.

Methods: Dapagliflozin initiators were identified in US-based administrative claims databases—Medicare (aged ≥ 65 years, years 2014-2017) and the HealthCore Integrated Research Database (HIRD) (aged 18-64 years, years 2014-2017)—and the Clinical Practice Research Datalink (CPRD), United Kingdom-based general practice records (aged ≥ 18 years, years 2012-2018). Clinical and demographic characteristics of the resulting study cohorts were described.

Results: We identified 46,801 dapagliflozin initiators (CPRD, 12,051; HIRD, 16,671; Medicare, 18,079). Across data sources, the proportion of patients using insulin at the time of dapagliflozin initiation was similar (CPRD, 13%; HIRD, 13%; Medicare, 17%), but the CPRD had higher proportions of dapagliflozin initiators adding dapagliflozin to other diabetes treatments (CPRD, 89%; HIRD, 66%; Medicare, 72%) and lower proportions initiating dapagliflozin as monotherapy (CPRD, 2%; HIRD, 13%; Medicare, 10%). The older Medicare cohort had higher baseline prevalences of most indicators of diabetes severity, comedication use, and comorbidity, including coronary heart disease (CPRD, 12%; HIRD, 9%; Medicare, 31%) and other cardiovascular disease (CPRD, 9%; HIRD, 3%; Medicare, 14%). The CPRD had lower recorded diagnoses of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hypertension than either US data source (CPRD, 54%; HIRD, 70%; Medicare, 90%).

Conclusions: Characteristics of patients with T2DM initiating dapagliflozin vary based on the source population and data source, potentially due to differences in age, data coding and record structures, and practice patterns. The Medicare cohort had higher levels of most comorbidities, as expected due to age. The patterns of dapagliflozin initiation in the CPRD differed from the US samples, which could be due in part to differing diabetes treatment approaches in the two countries. Using patient information from a variety of populations and practice settings is helpful in evaluating the safety of dapagliflozin.

4154 | Development of antipsychotic doses among persons with newly diagnosed schizophrenia - Ten years of follow-up

Antti Tanskanen[1], Marjaana Koponen[2], Markku Lähteenvuo[1], Jari Tiihonen[3] and Heidi Taipale[1]

[1]Niuvanniemi Hospital, Kuopio, Finland; [2]University of Eastern Finland, Kuopio, Finland; [3]Karolinska Institutet, Stockholm, Sweden

Background: Knowledge on antipsychotic dose trends in treatment of schizophrenia is scarce.

Objectives: The aim of this study was to investigate the development of antipsychotic dose in patients with incident schizophrenia over up to ten years of follow-up.

Methods: The study cohort included all persons newly diagnosed with schizophrenia during 1996-2014 in Finland, without antipsychotic use during the preceding year (N=8,342, median age 36, IQR 26-53; 56.3% men). The study cohort was identified based on first schizophrenia diagnosis recorded in inpatient care, and register-based data linkage covered years 1972-2017. Antipsychotic dispensings were modelled into drug use periods with PRE2DUP method, and local dose estimate was calculated at 6 month intervals up to 10 years after first schizophrenia diagnosis. Dose was calculated by sliding average of defined daily doses (DDDs), summed up from all antipsychotic drugs and using up to three purchases before the time point. Similarly, the number of concurrent antipsychotics (no use, monotherapy and polytherapy, referring to concurrent use of more than one antipsychotic) was measured at every time point.

Results: Six months after diagnosis, 74.7% of persons used at least one antipsychotic and the prevalence of polytherapy was 14.1%. At this point, mean antipsychotic dose was 1.27 (SD 0.91) DDDs per day and 17.5% were categorized to have a high dose (>1.5 DDDs per day). After ten years of follow-up, 80.1% used antipsychotics, 22.5% were defined as having antipsychotic polytherapy, mean dose was 1.43 (SD 1.10) DDDs per day and 26.5% had a high antipsychotic dose.

Conclusions: Antipsychotic dose, prevalence of polytherapy and high dose use increased during ten years of follow-up among persons with initially newly diagnosed schizophrenia.

4157 | Do early prescribers of new drugs have different risk management practices?

Nabarun Dasgupta[1], John R Brown[2], Patricia Rippetoe Freeman[2], Maryalice Nocera[1] and Svetla Slavova[2]

[1]University of North Carolina, Chapel Hill, NC; [2]University of Kentucky, Lexington, KY

Background: Uptake of new technology occurs first in "early adopters." We hypothesized that early prescribers of new medicines could likewise be identified, possibly influencing interpretation of early post-market assessments.

Objectives: Conduct a statewide prescriber survey to evaluate if self-described early prescribers have differences in risk management practices compared to later prescribers.

Methods: Planned hypothesis generating analysis of a larger survey on opioid prescribing, fielded by state licensing authority in Nov 2019. **Setting**: All DEA-registered Kentucky (US) physicians. **Exposure**: Self-reported affirmation of any of 3 statements: I prescribe new medications before others; I enjoy the variety of prescribing new medicines; I like to share with colleagues about new medicines I've prescribed. (Other options: I feel more comfortable using familiar medications, etc.). **Outcome**: Physician characteristics, opioid prescribing. **Analysis**: Descriptive univariable/bivariable stats

Results: Emails were delivered to 7631 physicians, with 651 respondents (8.5% - similar to other unincentivized physician surveys). After limiting to controlled substance prescribers and removing incommpletes, the analysis sample was n=349, with 83 (24%) early prescribers. Early adopters were disproportionately in early or late career (less than 15 or 35+ practice-years). The male:female ratio was 2:1 among respondents, but proportionately more females (26%) than males (19%) were early adopters. There were no differences in patient load, practice setting, or medical specialty except emergency medicine and general surgery were less likely; and oncology and OB/GYN were more likely to be early adopters. Early prescribers were more likely to use opioid risk stratification tools (OR 1.5; 0.85, 2.7). Abuse deterrent formulation (ADF) opioid prescribing was similar (OR 1.1; 0.65, 1.8). However, early adopters were more likely (OR 1.4; 0.73, 2.6) to prescribe newer non-OxyContin ADFs, with 93% endorsing "innovative nature of abuse-deterrence mechanisms" as a consideration. They supported legislation mandating insurance coverage for ADFs (OR 3.5; 1.6, 8.9), and more strongly endorsed technical solutions like electronic prescription monitoring programs and urine drug screens, while opposing prescribing limits.

Conclusions: In addition to prescribing newer medications, early adopters may differ in other healthcare delivery aspects that may impact care. The survey is being replicated in other states. Quantitative assessments will follow. Studies with historical controls may want to consider impacts of early adopters.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4190 | Sociodemographic and clinical predictors of prescription opioid use in a longitudinal community-based cohort study of middle-aged and older adults

Kristin Y Shiue[1,2], Nabarun Dasgupta[1,2], Rebecca B Naumann[1,2], Amanda E Nelson[3,4] and Yvonne M Golightly[1,3]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Chronic pain prevalence in the United States is likely to increase with an aging population. While opioids have commonly been prescribed to manage pain, their use may be more likely in certain patients.

Objectives: Assess predictors of prescription opioid use in an adult population with a high prevalence of chronic pain.

Methods: Data were from a community-based cohort of White and African American adults aged 50-90 years residing in predominantly rural Johnston County, North Carolina. Univariable and multivariable logistic regression models were used to evaluate sociodemographic and clinical factors in non-opioid users (n=795) at baseline (2006-2010) as predictors of opioid use at follow-up (2013-2015). Variables included age, sex, race, obesity (BMI≥30kg/m^2), polypharmacy (5+ medications), educational attainment (<12, ≥12 years), employment (unemployed, employed/retired), insurance (uninsured, public, private), Census block group household poverty rate (<12%, 12-24%, ≥25%), depressive symptoms (Center for Epidemiologic Studies Depression Scale ≥16 or depression diagnosis), perceived social support (moderate/poor [<19], strong [≥19]; Strong Ties Measure of Social Support, range 0-20), pain sensitivity (sensitive [<4kg], normal [≥4kg] pressure pain threshold), and pain catastrophizing (high [≥15], moderate/low [<15]; Pain Catastrophizing Helplessness Subscale, range 0-25).

Results: At follow-up, 13% (n=102) of participants were using prescription opioids. In univariable models, younger age, female sex, obesity, polypharmacy, unemployment, public (vs. private) health insurance, higher poverty, depressive symptoms, poorer perceived social support, pain catastrophizing, and elevated pain sensitivity were independently associated (p<0.05) with opioid use. In the multivariable model, younger age (60 vs. 70 years; adjusted odds ratio, 95% confidence interval=1.76, 1.12–2.77), polypharmacy (2.21, 1.27–3.85), high pain catastrophizing (2.12, 1.29–3.48), and depressive symptoms (1.93, 1.12–3.31) remained significant independent predictors.

Conclusions: The simultaneous assessment of a breadth of clinical and sociodemographic factors identified polypharmacy, pain catastrophizing, and depressive symptoms as modifiable predictors of prescription opioid use. These findings support the incorporation of pharmacological review and behavioral approaches into chronic pain management strategies. Further research is warranted to track changes in these factors as prescription opioid use declines nationwide

4232 | Understanding real-world use and survival with the use of anaplastic lymphoma kinase (ALK) inhibitors for ALK-positive non-small cell lung cancer: A Hong Kong-wide cohort study

Swathi Pathadka[1], Jesse Zhao[1], Joseph E. Blais[1], David C. L. Lam[2], Jessica P. Shami[1] and Esther W. Y. Chan[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong; [2]The University of Hong Kong, Hong Kong, Hong Kong

Background: Anaplastic lymphoma kinase (ALK) inhibitors have advanced the treatment of ALK-positive non-small cell lung cancer (NSCLC). There is limited real-world data on the treatment and outcomes in patients with ALK-positive NSCLC in the Asian population.

Objectives: To assess the treatment patterns and survival outcomes with the use of ALK inhibitors in Hong Kong.

Methods: We conducted a population-based cohort study using electronic medical database managed by the Hong Kong Hospital Authority. Patients treated with ALK inhibitors between 2013 and 2017 were followed-up until 2018. Patient characteristics and treatment patterns of ALK inhibitors, including a switch in therapy and treatment discontinuation were described. Using the Kaplan-Meier method, overall survival (OS) of patients treated with crizotinib was analyzed.

Results: Among 417 patients who received ALK inhibitors (median age, 57 years; 59.2% women), crizotinib was initiated as the first-line ALK-targeted therapy in 387 (92.8%), for a median treatment duration of 39 weeks. The majority of patients had confirmed lung adenocarcinoma (81.7%) and 15.3% of patients had brain metastases before receiving ALK inhibitors. More than half of the patients on crizotinib switched to either chemotherapy (18.8%) or a second-generation ALK inhibitor (36.2%) after a median period of 10 months. Nearly 20% of patients on crizotinib, 16% on ceritinib and 7% on alectinib discontinued therapy for more than 3 months. The median OS of patients treated with crizotinib was 10.4 months (95% confidence interval, 7.97-12.7).

Conclusions: In Hong Kong, crizotinib was the most common initial choice of treatment for ALK-positive NSCLC. Crizotinib appears to be associated with 10 months OS, but treatment discontinuation and switch in therapy due to disease progression occur frequently.

4262 | Prescribing pattern of antibiotics in children

Ching-Lan Cheng[1,2], Ju-Ling Chen[3], Yea-Huei Kao Yang[3] and Wen-Liang Lin[4]

[1]National Cheng Kung University, Tainan, Taiwan; [2]National Cheng Kung University Hospital, Tainan, Taiwan; [3]National Cheng Kung University, Tainan, Taiwan; [4]National Cheng Kung University Hospital, Tainan, Taiwan

Background: Antimicrobial Resistance (AMR) is a worldwide problem with the public. "Taiwan Antimicrobial Resistance, Prescribing and Efficacy in Neonates and Children Project (TARPEC)" is a multicenter study to estimate the magnitude of antimicrobial resistance in pediatrics in Taiwan.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To evaluate the utilization of neonatal and pediatric AMR blood stream infection (BSI) in survey study and the trend of antibiotic use in children stratified by age group in Taiwan by using claim database.

Methods: We conducted a prospective cohort study to collect clinical data by using the online surveillance system in four centers. We enrolled admitted children who aged younger than 18 years during August 2017 to July 2019. The 1-day point prevalence of prescription were calculated among all hospitalized neonates and pediatric patients at 8 am since at least midnight. The pattern of neonatal and pediatric AMR blood stream infection was evaluated. In addition, we conducted a retrospectively study by using National Health Insurance Research Database from January 1 2012 to December 31 2016, to analyze the utilization of antibiotics, focusing on the pediatric population. We also identified the antimicrobial regimen for bacteremia, sepsis of newborn (ICD-9/ICD-10 code:790.7/R78.81, 771.8/P36) among hospitalization children.

Results: In survey study, *Escherichia coli* (*E. coli*) (26%) was the most isolated pathogen among 105 subjects with BSI, followed by *Staphylococcus aureus* (*S. aureus*) (21%) and *Salmonella* (16%). More than 50% isolated *E. coli* was resistant to ampicillin/sulbactam and trimethoprim/sulphamethoxazole. *S. aureus* was resistant to clindamycin, erythromycin and oxacillin. Amoxicillin/beta-lactamase inhibitor and cefazolin were two highest prescribed abxs among inpatient setting. Prescription pattern was similar between medical center and regional hospital. Prescription rate was highest in 6~18 yrs old age group (around 61%), followed by 2~5 yrs old, 0~1 yrs old and lowest in 1~2 yrs old group (51%) during hospitalization. For children with bacteremia or sepsis, ampicillin and gentamicin were most prescribed (54 %) empirical combination therapy. In addition, third generation cephalosporins, such as cefotaxime, ceftazidime and ceftriaxone, were most frequently prescribed abxs for monotherapy.

Conclusions: *E. coli* was the most isolated pathogen in patients with BSI and resistant to ampicillin/sulbactam and trimethoprim/sulphamethoxazole inn survey study. In claim data study, different abxs prescription pattern was observed might due to different patient's characteristics between inpatients and outpatients.

4269 | Secular trends in first line treatment with disease modifying antirheumatic drugs in rheumatoid arthritis: An international real-world study by the OHDSI and EHDEN networks

Anthony G. Sena[1,2,3], Nigel Hughes[1], Emily S. Brouwer[1], Edward Burn[4,5], Jennifer Lane[5], Marcel de Wilde[3], Katia Verhamme[3], Peter R. Rijnbeek[2,3], Daniel Prieto-Alhambra[5] and Patrick B. Ryan[1,2,6]
[1]Janssen Europe, Middle East and Africa, United States of America, Titusville, NJ; [2]Observational Health Data Sciences and Informatics, New York, NY; [3]Department of Medical Informatics, Erasmus MC, Rotterdam, Netherlands; [4]Fundació Institut Universitari per a la Recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Barcelona, Spain; [5]Centre for Statistics in Medicine (CSM), Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; [6]Department of Biomedical Informatics, Columbia University, New York, NY

Background: International guidelines increasingly recommend early initiation of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) following diagnosis of rheumatoid arthritis (RA), with methotrexate (MTX) advised as the first line treatment. There is a scarcity of data on secular trends in the real-world use of csDMARDs in treatment of RA internationally.

Objectives: To characterize secular trends in first-line csDMARD treatment patterns during the first year following an RA diagnosis.

Methods: Fourteen real world databases from 9 countries mapped to the OMOP Common Data Model were included from the OHDSI network and EHDEN European project: Australian (IQVIA), Belgian (IQVIA), Estonian, France (IQVIA), Japanese (JDMC), Dutch (IPCI), Spanish (SIDIAP), UK (IQVIA THIN), and USA (IBM: CCAE, MDCR, MDCD, Optum: DOD and EMR). Patients were included starting at the earliest of: first diagnosis of RA or first DMARD with an RA diagnosis within 30 days. Patients must be 18 years or older and required 1+ year pre-index observation, and at least 1-year of follow-up after diagnosis of RA. The study period covered 2000-2018. Patients with previous non-RA inflammatory arthritis history were excluded. 15 DMARDs and minocycline were included for analyses, but only MTX, hydroxychloroquine (HCQ), sulfasalazine (SSZ) and leflunomide (LEF) monotherapy were available in all databases, with all others grouped as "other" for the analyses.

Results: We identified 323,547 newly diagnosed RA patients with a first-line csDMARD in the first year from index. Across all databases, MTX was the most prevalent first-line therapy with consistent usage. HCQ was the next most prevalent first-line therapy in Australia, Belgium, Estonia, France, Netherlands, and USA, with LEF as second most used in Spain until 2012 then changing also to HCQ. Despite consistent guidelines, the use of MTX as a first line treatment remained low (around 50%) in the US, Australian and UK data with no clear change over time. MTX as first-line therapy increased in Spain and the Netherlands until 2012, then decreased in favor of HCQ. Japan and Estonia had low use of MTX (<50%) initially, but slowly increased over time.

Conclusions: We observed evidence of heterogeneity in the management of RA across 9 countries. Despite published guidance for MTX to be first line therapy, data suggest that a large proportion of patients receive another csDMARD. The proportion of first-line MTX initiators has not increased over time despite international recommendations.

4273 | Geographical variation and prescribing trajectories of opioids in the Scottish primary care setting

Teng-Chou Chen[1], Amanj Kurdi[2,3] and Li-Chia Chen[1]
[1]Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom, Manchester, United Kingdom; [2]Strathclyde Institute of Pharmacy and Biomedical Science, University of Strathclyde, Glasgow, United Kingdom; [3]Department of Pharmacology, College of Pharmacy, Hawler Medical University, Erbil, Iraq

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: From 2015, opioid prescribing remained stable in Scotland due to the rising concerns of abuse and the implementation of deprescribing strategies. Although variation in opioid prescribing across practices has been identified associating with policies across health boards and population characteristics, the variation in longitudinal opioid prescribing trend and its associated factors have not been investigated.

Objectives: This study aimed to identify the longitudinal trajectory of opioid utilisation and its associated population factors in general practices in Scotland.

Methods: This cross-sectional study used the practice-level dispensing data from the NHS National Services Scotland and published statistics from 2016 to 2018. Practices that prescribed opioid analgesics and could be assigned characteristics of registrants were included. Monthly opioid utilisation in each practice was quantified using defined daily dose (DDD)/1000 registrants. The monthly opioid utilisation in 2017 and 2018 were compared with utilisation in 2016 and the difference between each calendar month was calculated. Group-based trajectory models were used to identify groups of practices with a similar trajectory based on the difference in monthly opioid utilisation. The association between characteristics of registrants and the trajectory groups was analysed by logistics regression and reported as odds ratio (OR) and 95% confidence interval (95%CI).

Results: Overall, 813 practices were included and categorized into four trajectories from 2016 to 2018. Of the 813 practices, most of them were grouped into the trajectory with stable (31.7%), decreased (29.4%) and largely decreased (10.3%) monthly opioid utilisation. However, 28.7% of practices were grouped into the trajectory with increasing opioid prescribing. More than 30% of practices in the Southern and Western Scotland were categorised into trajectory group with increasing opioid prescribing. Practices with more than 20% of registrants coming from the most deprived area were associated with a higher risk (OR: 2.3, 95%CI: 1.7, 3.1) of grouping into the trajectory with increasing opioid utilisation.

Conclusions: Increasing opioid utilisation over time was related to depriving socioeconomic status despite existing strategies to deprescribe opioids across general practices in Scotland. Further studies should explore the determinants associated with decreased opioid prescribing by applying individual-patient data.

4278 | Trajectories of use of biologic disease modifying anti-rheumatic drugs in rheumatoid arthritis: A cohort study of Tuscan patients, Italy

Irma Convertino[1], Sabrina Giometto[2], Rosa Gini[3], Massimiliano Cazzato[4], Giulia Valdiserra[1], Emiliano Cappello[1], Sara Ferraro[1], Marco Fornili[2], Giuseppe Turchetti[5], Valentina Lorenzoni[5], Leopoldo Trieste[5], Marta Mosca[4], Corrado Blandizzi[1,6], Marco Tuccori[6,1] and Ersilia Lucenteforte[2]

[1]Unit of Pharmacology and Pharmacovigilance, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Unit of Medical Statistics, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [3]Tuscan Regional Healthcare Agency, Florence, Italy; [4]Unit of Rheumatology, University Hospital of Pisa, Pisa, Italy; [5]Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy; [6]Unit of Adverse Drug Reactions Monitoring, University Hospital of Pisa, Pisa, Italy

Background: Adherence to biologic Disease Modifying Anti-rheumatic Drugs (bDMARDs) in rheumatoid arthritis (RA) patients is poorly reported, and its interpretation is complex due to recommended discontinuation of the drugs when remission of symptoms is achieved.

Objectives: To identify and characterize trajectories of bDMARDs in RA patients.

Methods: This is a population based retrospective cohort study using data collected in administrative healthcare databases of Tuscany, an Italian region. We included patients with a first dispensation of bDMARD (infliximab, adalimumab, certolizumab, etanercept, golimumab, abatacept, tocilizumab) from 2010 to 2015 (index date, ID); at least 1 year (y) of look-back period at ID; a RA diagnosis or a rheumatologic visit within 1y after ID; at least 3 dispensations of bDMARD. We excluded patients with dispensations of antineoplastic drugs or cancer diagnosis at baseline, or less than 3y of follow-up. We censored for cancer or pregnancy. We estimated adherence to bDMARD every three months through the Proportion of Day Covered and clustered longitudinal trajectories of adherence in groups. We described the clusters and compared baseline characteristics of patients across clusters.

Results: Out of 3,468 first bDMARD users with a RA diagnosis or visit and no history of cancer, 292 (8.4%) had less than 3 dispensations and 79 (2.3%) had less than 3y of follow-up. In the cohort of 3,097 patients, 67.2% were female. The mean age was 52.90 (SD 16.6). The index bDMARDs (ibD) were etanercept (1184 patients, 38.2%), adalimumab (998, 32.2%), infliximab (259, 8.4%), golimumab (234, 7.6%), abatacept (159, 5.1%), certolizumab (149, 4.8%), tocilizumab (114, 3.7%). We identified 3 clusters: in the 1st, including 1,213 patients, adherence was high for 2y, followed by a slow decrease; in the 2nd, 1,744 patients, adherence showed a steady state with moderate decrease over time; in the 3rd, 135 patients, adherence fell abruptly after 9 months. Gender and age did not predict cluster membership. History of fractures and number of specialist visits predicted the 2nd and the 3rd trajectory, respectively. The most common ibD were etanercept (35.7%), adalimumab (32.8%) and golimumab (10.1%) in the 1st group; etanercept (40.3%), adalimumab (32.5%) and infliximab (9.1%) in the 2nd; etanercept (34.8%), adalimumab (23.0%) and abatacept (13.3%) in the 3rd.

Conclusions: Three trajectories of adherence were identified: late decrease, slow and steady decrease, early and sudden decrease. Specialist visits, fractures, and ibD were predictive of the cluster membership.

4290 | The associations between personality traits and medication use, dietary supplement use and blood pressure control

Dianna F. M. de Vries[1], Julia C. Stingl[2] and Monique M. B. Breteler[1,3]

[1]German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany; [2]RWTH Aachen, Aachen, Germany; [3]University of Bonn, Bonn, Germany

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Personality traits have been associated with disease burden, adherence to treatment and reporting of adverse drug reactions. It is unknown whether personality is also associated with medication and supplement use.

Objectives: To assess the associations between personality traits and medication use, supplement use, and control of blood pressure.

Methods: We used data from the Rhineland Study, a population based cohort in Bonn, Germany that includes people aged ≥30 years. Information on medication use was collected in an interview. We assessed supplement intake using a Food Frequency Questionnaire and personality traits with the short Big Five Inventory. We quantified the associations between personality traits and the amount of drugs used (regularly, regularly without prescription, and as needed), dietary supplement use, intensive blood pressure lowering (antihypertensive treatment and systolic blood pressure <120 mmHg) and having uncontrolled blood pressure (≥140/90 mmHg), by using either multivariable logistic models or quasi-Poisson regression models (dependent count variables). Models were adjusted for age, sex and educational level. Personality traits were entered as independent variables (one trait per model) comparing persons in the fourth to those in the first quartile.

Results: The analyses were based on 3,502 out of 4,000 participants (mean age 55 years, standard deviation 13.9, 57% women). The main reason for exclusion was missing data on supplement use. Higher neuroticism level was associated with an increased amount of drugs used regularly (IRR 1.47, 95% confidence interval (CI) 1.32-1.64), regularly without prescription (IRR 1.87, 95%CI 1.37-2.57), and as needed (IRR 1.39, 95%CI 1.26-1.54), more use of supplements (OR 1.66, 95%CI 1.37-2.02), and an increased likelihood of intensive blood pressure lowering (OR 2.45, 95%CI 1.48-4.21). Higher agreeableness was associated with a lower amount of drugs used regularly (IRR 0.89, 95%CI 0.80-0.98) and a decreased likelihood of being on intensive blood pressure lowering treatment (OR 0.57, 95%CI 0.36-0.87). Higher openness was associated with increased use of supplements (OR 1.24, 95%CI 1.02-1.50). There were no associations between extraversion and conscientiousness and our outcomes of interest.

Conclusions: Individuals high on neuroticism may be at increased risk of suboptimal medication use due to their increased use of supplements and medication. Especially the increased use of non-prescribed and as needed medication, which is often not known to the physician, may increase the risk of unintended effects.

4291 | Persistently high levels of opioid utilization among older patients with urinary stone disease: Findings from the urologic diseases in America project

Lydia Feinstein[1], Julia B. Ward[1], Kevin C. Abbott[2], Tamara Bavendam[2], Ziya Kirkali[2], Erline Martinez-Miller[1] and Brian R. Matlaga[3]

[1]Social & Scientific Systems, Durham, NC; [2]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background: Urinary stone disease (USD) and its surgical treatment are typically very painful, but the scope of opioid utilization to mitigate USD-related pain is not well understood.

Objectives: To assess trends in the utilization of opioid agents among a U.S. representative sample of USD patients aged ≥65 years.

Methods: We analyzed data from USD patients aged ≥65 years in the 2006-2013 Centers for Medicare & Medicaid Services Medicare 5% Sample with full enrollment in Parts A, B, and D (N≈10,000 annually). A patient was considered to have experienced a kidney stone episode in a given calendar year if they had at least one Evaluation & Management claim with a qualifying ICD-9-CM diagnostic code indicative of kidney stones at any time during that year. The percentage of USD patients prescribed opioid agents was calculated annually over the study period. All results were assessed overall and stratified by age group, gender, and race/ethnicity.

Results: Approximately three-fourths of USD patients filled a prescription of any kind in the course of their treatment. Opioid agents were the most commonly prescribed pharmaceutical (range: 55-58%), followed by alpha blockers (range: 19-29%) and calcium channel blockers (range: 27-30%). The prevalence of opioid agonist prescription fills decreased with increasing age and was higher among women (range: 58-61%) compared to men (range: 51-56%). Black USD patients were also more likely to be prescribed opioid agonists (range: 60-65%) compared to other racial/ethnic groups (range: 45-58%). These trends were consistent across all study years.

Conclusions: Opioid agents are commonly prescribed to older USD patients in the United States, and this practice persisted over the study period. An understanding of the scope of opioid prescription practices among USD patients is the first step in a pathway towards reducing use of opioids for analgesia. Given how commonly opioids are utilized among USD patients, and given the recognized health risks associated with these agents, developing clinical pathways that decrease reliance on opioid agents is particularly important.

4310 | Drug utilization disparities regarding rural-urban area and economic status in primary healthcare in china: A nationwide cross-sectional survey

Mengyuan Fu[1,2], Haishaerjiang Wushouer[1,3], Luwen Shi[1,4] and Xiaodong Guan[1,2,4]

[1]School of Pharmaceutical Sciences, Peking University, Beijing, China; [2]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [3]Center for Strategic Studies, Chinese Academy of Engineering, Beijing, China; [4]International Research Center for Medicinal Administration, Peking University, Beijing, China

Background: The primary healthcare institutions (PHIs) in China, which provide basic clinical care to a fifth of the world's population, have 4.4 billion outpatient visits in 2018. However little research has been focused on the nationwide variation of drug utilization quality in Chinese primary healthcare in recent years.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To evaluate the outpatient drug utilization disparities regarding rural-urban areas and economic status in primary healthcare in China.

Methods: We conducted a nationwide cross-sectional survey for PHIs in China from October, 2017 to April, 2018. A total of 283 PHIs (195 rural vs. 88 urban) were randomly selected from 9 provinces, in various regions and at various economic levels (4 levels based on capita GDP of the city), using multi-stage stratified sampling method. Outpatient prescriptions in 2017 were randomly selected from sampled institutions and analyzed retrospectively. Average number of drugs per prescription, antibiotic prescription rate, multi-antibiotic prescription rate, injection prescription rate and national essential medicine (NEM) prescription rate were used as outcome measures to evaluate drug utilization. Generalized estimating equations were applied to generate population-weighted average comparisons using model adjusting for other covariates (region, patient gender, patient disease type, etc.). Ethics approval was obtained from Peking University Institution Review Board.

Results: 388,361 prescriptions were included in total. PHIs in rural areas prescribed larger number of drugs per prescription (adjusted number, 2.6 vs. 2.3), higher proportion of antibiotic, multi-antibiotic, injection and NEM prescribing (adjusted proportion, 23.1% vs. 16.2%; 16.4% vs. 13.9%; 26.5% vs. 16.5%; 71.3% vs. 67.7%). PHIs in lower economic status have relatively more drugs per prescription (adjusted number, lowest quartile of economic level to highest 3.4-1.9), higher proportion of antibiotic, multi-antibiotic, injection and NEM prescribing (adjusted proportion, lowest quartile of economic level to highest 23.2-14.7%; 18.4-11.0%; 21.9-20.3%; 75.7-60.8%).

Conclusions: Substantial variations regarding rural-urban areas and economic status were identified in outpatient drug utilization in primary care in China. More strategies aiming at promoting prescribing practices and quality use of medicines of primary healthcare, especially in rural and economically underdeveloped areas, are required.

4318 | Increasing use of muscle relaxants in the US 2005-2016

Samantha E. Soprano, Sean Hennessy, Warren B. Bilker and Charles E. Leonard
University of Pennsylvania, Philadelphia, PA

Background: Little is known about United States (US)-based trends in skeletal muscle relaxant (SMR) use, despite important safety concerns especially among older adults and in persons concomitantly exposed to opioids.

Objectives: To measure US trends in SMR utilization over a 12-year period.

Methods: We conducted a repeated cross-sectional study using 2005-2016 US Centers for Disease Control and Prevention National Ambulatory Medical Care Survey data. The study population consisted of ambulatory care patient encounters of non-federally funded, office-based physicians. We quantified ambulatory care visits—overall and stratified by calendar year, geographic region, patient age, sex, and race—in which an SMR was newly prescribed or continued. Among visits in which an SMR was newly prescribed, we assessed all diagnoses. Concomitant medications were analyzed We used survey visit weights to estimate nationally representative measures and further generated age-standardized rates by geographic region using US census data.

Results: The number of US ambulatory care visits in which an SMR was either newly prescribed or continued as ongoing therapy nearly doubled from 15.5 million in 2005 to 30.7 million in 2016. While visits for new SMR prescriptions remained stable, office visits with continued SMR therapy tripled from 8.5 million visits in 2005 to 24.7 million visits in 2016. SMR users were predominantly female (52.8%), white (53.7%), and non-Hispanic (81.3%). The most common diagnoses were related to issues of back pain. Older adults accounted for 22% of patients receiving an SMR in 2016, accounting for a 3-fold increase from 2005. Concomitant opioid use was documented in 67.2% of all visits with a continuing SMR prescription. Age standardized rates revealed a 325.1% increase in continued SMRs prescriptions in the Northeast region, followed by the Midwest with a 297.6% increase.

Conclusions: SMR use in the US has increased rapidly, which is worrying given prominent adverse effects and limited long-term efficacy data associated with their use. Use in older adults continued to rise over the study period, despite labeling by the American Geriatric Society as potentially inappropriate in this population. Approaches are needed to limit long-term use of SMRs, especially in older adults, akin to approaches to minimize long-term use of opioids and benzodiazepines.

4328 | Trends of non-insulin antidiabetic medicines prescribing in Romania during 2012-2018

Camelia Bucsa, Adriana Rusu, Andreea Farcas and Cristina Mogosan
"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background: Several new antidiabetic medicines (ADMs) were authorized during the last decades and this resulted in changes in diabetes therapy.

Objectives: To analyze the market trends of ADMs in Romania during 2012-2018 and to describe the utilization of the new ADMs (glucagon-like peptide-1 receptor agonists [GLP-1], dipeptidyl peptidase-4 inhibitors [DPP-4] and sodium-glucose transport protein 2 inhibitors [SGLT-2]) during 2018.

Methods: We conducted a retrospective analysis of pharmacy claims data from IQVIA Romania database from January 2012-December 2018. For trends analysis, we used nationally extrapolated data (IQVIA proprietary algorithm with maximum 2% error) and for the detailed 2018 analysis, we used exact data retrieved from the approximately 4000 pharmacies (approx. 70% of the overall market). We analyzed the reimbursed prescriptions that included at least one ADM (all

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ATC10 codes) as defined daily doses (DDDs)/1000 inhabitants/day and number of prescriptions (for 2018).

Results: The total number of ADMs DDDs/1000/day increased by 41.74% between 2012 (48.08) and 2018 (68.15) at the national level. A comparison between the successive years showed a continuous increase in ADMs consumption (the highest of 9.20% between 2016-2017), except for the years 2013-2014 where a slight decrease was observed (0.68%). Metformin was the most prescribed ADM and its consumption increased constantly during 2012-2018 (14.01-22.89 DDDs/1000/day), also gaining in share of the non-insulin ADMs (39.81-44.52%). Sulphonylureas (SU) were the 2nd most prevalent ADM with a constant increase in prescribing between 2012-2017 and slight decrease during 2017-2018 (15.91-20.34 and 19.73 DDDs/1000/day, respectively), but a continuous decrease of its share in the non-insulin ADMs during 2012-2018 (45.20-38.36%). A steady increase was observed for the new ADMs (GLP-1, DPP-4, and SGLT-2) throughout the study period with a share of 7.11% of the non-insulin ADMs in 2018. In 2018, a total number of 1060146 ADM prescriptions were registered, mostly issued by diabetologists and family practice physicians. Most of the prescriptions with DPP-4 inhibitors (28%) had a SU co-prescribed, of the SGLT-2 inhibitors (51%) had metformin and of GLP-1 analogs had both metformin or SU in equal proportions (approx.31% each).

Conclusions: An overall trend of market increase was found for ADMs between 2012-2018, corresponding to the increase in the prevalence of diabetes in Romania. As expected, an increased prescription of new ADMs and decreased of SU was found during the time frame of our analysis.

4329 | Utilization characteristics for inhaled corticosteroid-based asthma medications in the sentinel distributed database

Tancy C. Zhang[1], Inna Dashevsky[1], Yan Li[2], Marie C. Bradley[3], Jianmeng Chen[4], Stacy Chin[2], Sandra DeLuccia[1], Efe Eworuke[3], Judith C. Maro[1], Yunzhao Ren[4], Rongmei Zhang[5], Chandrahas Sahajwalla[4], David Martin[6], Sally Seymour[2], Kenneth Quinto[6], Robert Busch[2] and Catherine A. Panozzo[1]

[1]Harvard Pilgrim Health Care Institute and Harvard Medical School, Boston, MA; [2]Division of Pulmonary, Allergy, and Rheumatology Products, Office of Drug Evaluation II, Office of New Drugs, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD; [3]Division of Epidemiology, Office of Surveillance and Epidemiology, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD; [4]Division of Clinical Pharmacology II, Office of Clinical Pharmacology, Office of Translational Science, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD; [5]Office of Biostatistics, Office of Translational Science, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD; [6]Office of Medical Policy, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD

Background: In randomized clinical trials, inhaled corticosteroid (ICS)-based medications have demonstrated effectiveness on asthma endpoints. Despite their potential benefit, real-world data describing medication adherence across large asthma populations are limited.

Objectives: To estimate proxies of medication adherence including the number of dispensings and proportion of days covered (PDC) over a one-year follow-up among ICS-based asthma medication users in the U.S. Food and Drug Administration's Sentinel System.

Methods: We conducted a retrospective cohort study and identified two ICS-based asthma medication user cohorts in Sentinel from January 2008 to July 2019, including: 1) ICS monotherapy and 2) ICS/long-acting beta-agonist fixed dose combination therapy (ICS/LABA). Cohort entry was defined by National Drug Codes, indexing on the first qualifying ICS-based dispensing. We selected users aged ≥18 years with continuous enrollment in health plans and an asthma ICD-9/10-CM diagnosis in the 183 days prior to the index date. Users with other respiratory comorbidities, including chronic obstructive pulmonary disease, in the 183 days prior to and including the index date were excluded. We further excluded users with ≥2 dispensings of other long-acting asthma maintenance medications during the 365 days after and including the index date. We required all users to be continuously enrolled in health plans in the 365 days after the index date to facilitate calculation of dispensings and PDC.

Results: We identified 802,627 ICS monotherapy users (mean age ± SD: 54 ± 16 years; 69% female) and 1,188,694 ICS/LABA users (mean age ± SD: 58 ± 15 years; 66% female). During a fixed one-year follow-up, ICS and ICS/LABA users filled their prescriptions a median of 2 (interquartile range (IQR): 1-4) and 3 (IQR: 2-6) times, respectively. The median PDC was 25% (IQR: 8-47%) for ICS and 33% (IQR: 16-61%) for ICS/LABA.

Conclusions: In our data, ICS/LABA users had a higher median number of dispensings and had a numerically higher PDC compared to ICS users. Over the one-year follow-up, we observed a median PDC ranging from roughly one-quarter to one-third for asthma medications intended for chronic daily use. Real-world data on utilization metrics such as the PDC may reveal inconsistencies between clinical recommendations and proxies of adherence, informing the design of future comparative effectiveness analyses.

4334 | Applicability of renal outcome trials of canagliflozin to the real world: Implications from comparisons of characteristics between trial patients and real-life patients

Ling-Chen Hsu[1], Kai-Cheng Chang[1,2], Shih-Chieh Shao[3,2], Hui-Yu Chen[1], Yuk-Ying Chan[4] and Edward Chia-Cheng Lai[2]

[1]Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]National Cheng Kung University, Tainan, Taiwan; [3]Keelung Chang Gung Memorial Hospital, Keelung, Taiwan; [4]Chang Gung Medical Foundation, Taoyuan, Taiwan

Background: A well-known randomized controlled trial (RCT), CREDENCE, demonstrated patients receiving canagliflozin were

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

associated with lower risk of renal failure in type 2 diabetes patients with diabetic nephropathy. However, the RCT was conducted under ideal conditions and included participants who were highly selected and may differ from real-life patients, leaving the question whether the trial is applicable to the real world.

Objectives: To compare the characteristics between trial participants and real-life patients in order to evaluate the applicability of RCT to the real world.

Methods: We analyzed the data from the Chang Gung Research Database (CGRD), which is a multi-institutional electronic medical records database covering approximately 1.3 million individuals (6% of Taiwan's population). We selected a cohort of patients newly receiving canagliflozin for type 2 diabetes treatment from August 2018 to December 2019 from CGRD. We applied additional inclusion criteria to CGRD patients based on criteria from the CREDENCE trial, and calculated the proportion of patients included for each criterion. The additional criteria were: (1) estimated glomerular filtration rate (eGFR) ranging from 30-90 mL/min/1.73 m^2, (2) urine albumin to creatinine ratio (UACR) ranging from 300-5000 mg/g and (3) treatment with renin-angiotensin system (RAS) blockade.

Results: We identified a cohort of 1,479 type 2 diabetes patients receiving canagliflozin from CGRD. We found the mean age of patients was 60.7 (SD 11.9) and 62.9 (SD 9.2) in the CGRD and CREDENCE trial, respectively. The proportion of female patients was 39.0% in CGRD and 34.6% in the CREDENCE trial. When we applied all criteria from the CREDENCE trial, only 5.4% of patients from the CGRD qualified for inclusion. We found 64.1% of CGRD patients' eGFR ranged from 30-90 mL/min/1.73 m^2; 13.3% of CGRD patients' UACR ranged from 300-5000 mg/g, and 63.9% received RAS blockade.

Conclusions: We found that only a low proportion of type 2 diabetes patients receiving canagliflozin in the real-world practice setting was eligible under the selection criteria for the CREDENCE trial. This finding highlights that careful consideration must be placed on applicability of results from trials to real-life patients.

4343 | Changes in therapeutic strategy in metastatic castration resistant prostate cancer between 2012 and 2014 from the French nationwide claims database

Nicolas H. Thurin[1], Magali Rouyer[1], Jérémy Jové[1], Marine Gross-Goupil[2], Thibaud Haaser[2], Xavier Rebillard[3], Michel Soulié[4], Gérard de Pouvourville[5], Camille Capone[6], Marie Pierrès[6], Stéphanie Lamarque[1], Emmanuelle Bignon[1], Cécile Droz-Perroteau[1], Nicholas Moore[1,2] and Patrick Blin[1]

[1]Bordeaux PharmacoEpi, INSERM CIC1401, Université de Bordeaux, Bordeaux, France; [2]CHU de Bordeaux, Bordeaux, France; [3]Clinique Beau Soleil, Montpellier, France; [4]CHU de Toulouse, Toulouse, France; [5]ESSEC, Cergy-Pontoise, France; [6]Janssen, Issy les Moulineaux, France

Background: Therapeutic strategy in mCRPC has evolved significantly since 2011 in France, when abiraterone acetate and enzalutamide indication were extended to 1st line mCRPC treatment (respectively in 2012 and 2014). France has a National Healthcare System database (SNDS) covering 99% of the population and allowing the assessment of mCRPC management.

Objectives: To describe the evolution of mCRPC management between 2012 and 2014.

Methods: A validated algorithm was used to identify patients in SNDS (2007-2016) and form two cohorts: mCRPC patients initiating a 1st line treatment in 2012, and mCRPC patients initiating a 1st line treatment in 2014. First line treatments considered were abiraterone acetate, docetaxel and enzalutamide. Previous prostate cancer stages before mCRPC status were defined according to the estimated date of castration resistance and 1st metastases management as non-metastatic hormonosensitive prostate cancer (nmHSPC), metastatic hormonosensitive prostate cancer newly diagnosed (NDx mHSPC) or progressive (progressive mHSPC), and non-metastatic castration resistant prostate cancer (nmCRPC).

Results: In France, patients initiating a 1st line treatment were respectively 2 921 out of 11 668 prevalent mCRPC in 2012 vs. 3 949 out of 12 951 mCRPC in 2014. Respectively in 2012 and 2014, previous stage of prostate cancer before mCRPC were: nmHSPC 47% and 52%, NDx mHSPC. 15% and 15%, progressive mHSPC 18% and 15%, nmCRPC 20% and 18%. In the 2012 cohort, abiraterone acetate was the 1st line treatment for 18% of the patients, while docetaxel was used for 81% of patients with few variations according to NDx mHSCP, progressive mHSCP, nmHSCP and nmCRPC stage: 87%, 77%, 80% and 81%, respectively. In the 2014 cohort, the 1st line treatments were abiraterone acetate for 62% of the patients, docetaxel for 31%, and enzalutamide for 5%. Patients coming from progressive mHSCP, nmHSCP and nmCRPC were mostly treated with abiraterone (respectively 61%, 62% and 72%). Patients coming from NDx mHSCP stage were almost equally treated by abiraterone (48%) and docetaxel (46%).

Conclusions: Between 2012 and 2014, the mCRPC 1st line treatment shifted from docetaxel for 4 out of 5 patients to abiraterone acetate for 3 out of 5.

4348 | Global trends in anti-dementia medications consumption in 66 countries/regions from 2008 to 2018

Chengsheng JU

School of Pharmacy, University College London, London, United Kingdom

Background: Worldwide, around 50 million people have dementia, with nearly 60% living in low/middle-income countries. Anti-dementia drugs are widely prescribed for the symptomatic treatment of dementia. Secular trends of anti-dementia drug consumption are important to understand the changes in clinical practice in managing dementia.

Objectives: To determine trends in anti-dementia medications consumption between 2008 and 2018 in 66 countries regions.

Methods: This is a descriptive study nested within the wholesale data from the IQVIA-Multinational Integrated Data Analysis System

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

database on anti-dementia medications sales in 66 countries and regions from 2008 to 2018, stratified by country income level (Low/Middle-income countries (LMICs), *n*=28; High-income countries (HICs), *n*=36; pooled regions, *n*=2). We analysed data on anti-dementia drugs, namely, donepezil, memantine, rivastigmine and galantamine. The consumption per year was estimated from defined daily dose (DDD: WHO defined daily dose, which takes into account the size, strength and form of each pack and reflects average dosing) per 1000 inhabitants per day. Mid-year population estimates and income levels of each country were obtained from the World Bank. Changes over time were quantified as percentage changes and compound annual growth rates (CAGR) in consumption per person. Percentage of each anti-dementia drug consumption over the total anti-dementia drug consumption was used to assess inter-country differences.

Results: Total anti-dementia drug consumption increased from 1.06 to 1.34 DDD per 1000 inhabitants per day between 2008 to 2018 (LMICs: 0.10 to 0.45; HICs: 4.79 to 5.04) with CAGR=2.30%. The increase was mainly driven by the LMICs (CAGR=15.97%) in comparison to the HICs (CAGR=0.51%). The trends varied between countries with the interquartile range (IQR) of CAGR from 5.63% to 18.98%. The overall consumption from 2008 to 2018 increased for rivastigmine (CAGR=6.45%), donepezil (CAGR=2.59%) and memantine (CAGR=1.30%), but decreased for galantamine (CAGR=-0.14%). In 2018, the most commonly used anti-dementia drug globally was donepezil with 49.75% of total sale volume, followed by memantine (32.65%), rivastigmine (11.24%) and galantamine (6.36%),

Conclusions: There was an overall increasing trend in anti-dementia medication consumption globally. The rate of increase was greater in LMICs. The disparity in the use of anti-dementia drugs between countries and regions suggests a need for consistent and evidence-base guidelines guiding optimal treatment for dementia.

4366 | Treatment patterns in people with Parkinson's disease in the United States and the association with cardiovascular disease

Loes C. A. Rutten-Jacobs[1], Spyros Roumpanis[1], Yutong Liu[2] and Preciosa M. Coloma[1]

[1]F. Hoffmann-La Roche Ltd., Basel, Switzerland[2]Genesis Research, Hoboken, NJ

Background: Limited data are available on how comorbidities impact treatment patterns in people with Parkinson's disease (PD). One such important comorbidity is cardiovascular disease (CVD), but its association with PD treatment patterns has not been described.

Objectives: 1) Describe treatment patterns in people with PD; 2) Evaluate the association of CVD with these patterns.

Methods: This retrospective cohort study used Truven MarketScan Commercial and Medicare Supplemental databases, 2007-2018. We identified people with incident PD by selecting those with two PD-diagnosis claims (ICD-9 332.0 and/or ICD-10 G20) and no PD claim or use of any PD medication for ≥12 months beforehand. Treatments of interest were levodopa and levodopa combination therapies (LD), dopamine agonists (DA) and monoamine oxidase B inhibitors (MAO-Bi). CVD included cerebrovascular, peripheral, cardiac and hypertensive diseases. Presence of a CVD claim within 6 months prior and 6 months post the first PD diagnosis claim was summarized. Events of interest were PD treatment initiation and switch-to or add-on of another PD treatment class. Cox proportional hazards analysis was used to evaluate the age and sex-adjusted association of CVD with the occurrence of the events of interest.

Results: The study cohort comprised 38,828 people with incident PD (40.4% women; median [interquartile range (IQR)] age 74 [64-82] years; median [IQR] follow-up time: 2.8 [1.8-4.4] years). 72.5% of people with PD were treated at any time during the follow-up period; LD was the first-line therapy for most (72.0%), followed by DA (14.9%) and MAO-Bi (10.0%). CVD was present in 73.1%. People with PD and concurrent CVD were less likely to initiate treatment during follow-up (hazard ratio (HR) 0.96 (95% CI 0.93-0.99) for LD; HR 0.82 (95%CI 0.79-0.86) for DA; HR 0.67 (95% CI 0.64-0.71) for MAO-Bi). In those with LD as first-line therapy, the 1-year probability to switch or add-on of PD treatment was 14.2% (95% CI 13.8%-14.7%). The corresponding probabilities for DA and MAO-Bi were 33.2% (95% CI 31.8%-34.7%) and 43.5% (95% CI 41.7%-45.4%) respectively. Concurrent CVD was negatively associated with switch-to or add-on another PD treatment class for people with LD as first-line treatment (HR 0.81 (95%CI 0.76-0.86)) or DA (HR 0.79 (95%CI 0.73-0.87)) but not MAO-Bi (HR 0.96 (95% CI 0.87-1.06)).

Conclusions: LD was the most common first-line treatment in newly diagnosed people with PD. Those with concurrent CVD were less likely to initiate treatment during the study period and less likely to switch-to or add-on another treatment if the initial treatment was LD or DA.

4368 | Antihypertensive medicine use in the Baltic states between 2008 and 2018

Indre Treciokiene[1,2], Nomeda Bratcikoviene[3,4], Jolanta Gulbinovic[5], Bjorn Wettermark[6] and Katja Taxis[2]

[1]Vilnius University, Vilnius, Lithuania; [2]University of Groningen, Groningen, Netherlands; [3]Vilnius Gediminas Technical University, Vilnius, Lithuania; [4]Vilnius University, Vilnius, Lithuania; [5]Vilnius University, Vilnius, Lithuania; [6]Uppsala University, Uppsala, Sweden

Background: High blood pressure is an important risk factor for cardiovascular death and disability. High prevalence of hypertension is seen in all three Baltic States, but little is known about use of antihypertensives.

Objectives: The aim of this study is to compare utilization of antihypertensive medicines in Estonia, Latvia and Lithuania over 11-years.

Methods: Wholesale data from the National retail audit IQVIA was used to determine the use of antihypertensive medicines in 2008-2018. The ATC/DDD methodology was used to calculate utilization of renin angiotensin system (RAS) inhibitors, including

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

angiotensin converting enzyme inhibitors -ACEi (C09A and C09B) and angiotensin II receptor blockers - ARBs (C09C and C09D), calcium channel blockers (C08), beta receptor blockers (C07), diuretics (C03) and central acting antihypertensives (C02A). The results were expressed in DDD per thousand inhabitants per day (DDD/TID). Time series analysis was used to analyze trends. ANOVA and Kruskal-Wallis tests were used to test differences between countries.

Results: The total use of antihypertensive drugs was 372.0 DDD/TID in Estonia, 267.0 DDD/TID in Latvia and 379.5 DDD/TID in Lithuania in 2018. The utilization increased by 10.88 DDD/TID (95% CI: 7.13 - 14.63), 8.04 DDD/TID (95% CI: 4.57 - 11.52) and 6.42 DDD/TID (95% CI: 2.44 - 10.41) annually, respectively. The use of all classes increased, except calcium channel blockers. Most frequently used class in 2018 was RAS inhibitors, followed by beta-blockers in all three Baltic countries. The use of central acting antihypertensives was highest in Lithuania, 30.9 DDD/TID, compared to 3.01 DDD/TID in Estonia and 16.17 DDD/TID in Latvia (p=0.000001) in 2018. Use of fixed-dose combinations increased from 30.3 to 94.9, from 33.7 to 87.1 and from 28.2 to 106.6 DDD/TID in Estonia, Latvia and Lithuania, respectively.

Conclusions: The use of antihypertensive medicines increased in the Baltic states, mostly driven by RAS inhibitors, beta-blockers and fixed-dose combinations. Striking differences in low overall use of antihypertensives in Latvia and high use of central acting substances in Lithuania were detected.

4402 | Characterizing real-world patterns of early childhood vaccination

Anne M. Butler[1], Jason G. Newland[2], John M. Sahrmann[1], Caroline A. O'Neil[1], Sena Sayood[1] and Leah J. McGrath[3]

[1]Washington University School of Medicine, St. Louis, MO; [2]Washington University School of Medicine, St. Louis, MO; [3]NoviSci, Durham, NC

Background: Vaccine hesitancy is increasingly common, but knowledge is limited on the effects of delayed vaccine schedules. Prior to performing comparative effectiveness studies, more information is needed on patterns of childhood vaccination.

Objectives: To characterize patterns of vaccine delay among commercially-insured children in the United States.

Methods: Using the IBM® MarketScan® Commercial Database, we identified infants who received first dose of diphtheria-tetanus-acellular pertussis (DTaP) vaccine at 38 to 92 days of age from October 1, 2009 to June 30, 2017. We ascertained injectable and oral vaccine antigens (DTaP, polio, pneumococcal conjugate, rotavirus, Haemophilus influenza type b (Hib), measles, mumps, rubella, and varicella). We used CPT codes to collect vaccine administration history on antigen, formulation, dose, and date. Timely receipt was defined as concomitant administration of the CDC-recommended number of antigens during the following time windows: 2, 4, 6, and 12-15 months of age (grace period: -7, +21 days). We generated heat maps to illustrate age distributions at receipt of specific antigens and doses. We created Sankey diagrams to illustrate the number of antigens received concomitantly during each time window and depict transitions to different states over time (e.g., no vaccine delay to vaccine delay). For each antigen and dose, we estimated the cumulative incidence of receipt using inverse probability of censoring weights.

Results: Among 1,066,216 eligible infants, the majority (84%) concomitantly received all 5 CDC-recommended antigens at 2 months of age while others only received 1 (1%), 2 (2%), 3 (4%), or 4 (9%) antigens. Many vaccinations were delayed - 30% of children did not receive all recommended antigens concomitantly at 4 months, and 39% did not at 6 months. The heat map shows wide variation in age at vaccination. For several antigens including Hib, measles, mumps, rotavirus, rubella, and varicella, the cumulative incidence increased steeply at ≥2 time points, suggesting vaccine delay for some infants. For example, the first dose of Hib was administered to 85% of infants by 2 months of age, with subsequent small but distinct increases at 4, 6, 12, and 15 months of age.

Conclusions: Using real-world data to study early childhood vaccination patterns, we observed evidence of substantial deviation from the CDC-recommended schedule, consistent with reports of increasing vaccine hesitancy. These results expand current knowledge on the magnitude and timing of antigen- and dose-specific vaccine delay on a population level.

4405 | Prescribing trends of antidepressants and coprescription with other psychotropic medications for children and adolescents in primary care in the United Kingdom, 2000-2018

Dai Cao[1], Lara Fraga[2], Emma Fergusson[3], Sophie Dell'Aniello[4], Hui Yin[4], Soham Rej[5], Laurent Azoulay[1,4,6] and Christel Renoux[1,4,7]

[1]McGill University, Montreal, QC, Canada; [2]Universidade Nove de Julho (UNINOVE), Sao Paolo, Brazil; [3]Oxford University, Oxford, United Kingdom; [4]Centre for Clinical Epidemiology, Jewish General Hospital, Montreal, QC, Canada; [5]McGill University, Montreal, QC, Canada; [6]McGill University, Montreal, QC, Canada; [7]McGill University, Montreal, QC, Canada

Background: An increase in antidepressant prescriptions in children and adolescents has been documented in the United Kingdom (UK) since the 2000s but no information is available on recent trends. Moreover, little is known about the coprescription with other psychotropic medications.

Objectives: To describe time trends in antidepressant prescriptions and coprescription with other psychotropic medications in UK children and adolescents between 2000 and 2018.

Methods: Using the Clinical Practice Research Datalink, we defined a cohort of all patients aged 5-17 years between 1 January 2000 and 31 December 2018. Using Poisson regression, we estimated the yearly rates of patients newly treated with antidepressants from the following classes: selective serotonin reuptake inhibitors (SSRIs), other second-generation antidepressants, and tricyclic antidepressants (TCAs). We also estimated the rate ratio (RR) of patients newly treated

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with antidepressants over the last 10 years. Finally, we calculated the percentage of patients with a same-day coprescription with other psychotropic medications (antipsychotics, mood stabilizers, anxiolytics, and stimulants).

Results: After a 42% decline from 2000 to 2005 (399.3 to 230.7 per 100,000 person-years), the rate of children and adolescents newly prescribed antidepressants increased from 2006 onwards. From 2008 to 2018, the rate increased from 254.3 to 471.2 per 100,000 person-years (RR 1.97, 95% confidence interval 1.96-1.99). The rate was higher in girls and in adolescents aged 15 to 17 years during the entire study period. SSRIs were the most commonly prescribed antidepressant class (70% of all antidepressant prescriptions), followed by TCAs (28%). In 2018, 81% of prescriptions were for SSRIs, 17% for TCAs and 2% for other antidepressants. Overall, 5% of new users of antidepressants had at least one same-day coprescription for another psychotropic medication during the study period, 51% of which had no previous prescription for a psychotropic medication. The percentage of patients with a coprescription rose from 2.6% of patients in 2000 to 6.4% in 2018. In 2018, coprescription was mostly for anxiolytics (62%) and antipsychotics (25%), and 93% of patients had only one psychotropic drug prescribed with the antidepressant.

Conclusions: Antidepressant prescriptions increased steadily for more than a decade in children and adolescents, accompanied by a rise in coprescription for other psychotropic medications. Further research is needed to offer potential explanations for the trends observed.

4431 | Trends and characteristics in cough prescription use in ambulatory care settings in the United States: 2003-2016

Seonkyeong Yang, Juan M. Hincapie-Castillo, Ching-Yuan Chang, Debbie L. Wilson and Jenny Lo-Ciganic
University of Florida, Gainesville, FL

Background: In response to the US opioid epidemic, numerous policies have been implemented to reduce inappropriate opioid prescribing in recent years. Gabapentin, a prescription with emerging safety concerns due to its potential abuse and risk of overdose, is recommended by the 2015 American College of Chest Physicians guidelines as a treatment option for unexplained chronic cough. It is often used off-label. Little is known of the prescription cough medication utilization patterns over time in light of these factors.

Objectives: To examine the trends, patient and prescriber characteristics in the use of antitussives containing opioids and gabapentinoids in US ambulatory care settings.

Methods: This cross-sectional study used 2003-2016 National Ambulatory Medical Care Survey data. We included adult (≥18 years) visits with infection or non-infection related cough as a visit reason (hereafter cough-related visits). We excluded visits with any cancer or benign respiratory tumor diagnoses. Among cough-related visits, we used logistic regression to examine the trends in the use of antitussives containing codeine or hydrocodone, and gabapentinoids (i.e., gabapentin and pregabalin).

Results: Of 385 million cough-related visits from 2013 to 2016, 24.6% were infection-related. The total number of cough-related visits declined from 42.3/1000 visits in 2003 to 31.6/1000 visits in 2016. Among cough-related visits, the prescribing prevalence was 5.5% for codeine, 4.4% for hydrocodone, and 1.6% for gabapentinoids. Cough-related visits with gabapentinoid prescriptions were more likely in patients aged ≥65 years (codeine: 20.4%; hydrocodone: 21.5%; gabapentinoid: 44.0%) and patients having ≥2 chronic conditions (codeine: 35.0%; hydrocodone: 25.4%; gabapentinoid: 62.2%). Over 60% of cough-related visits with codeine or hydrocodone prescriptions were paid by commercial insurance, and 60% of cough-related visits with gabapentinoid prescriptions were paid by public insurance. Primary care physicians were the major prescribers (>80%) of cough medications in the cough-related visits. The number of cough-related visits where hydrocodone was prescribed substantially decreased (6.0% to 1.7% from 2003 to 2016; P_{trend} =0.003), while codeine use remained stable (5.5% to 5.8%; P_{trend} =0.89) and gabapentinoid use increased significantly (0.6% to 2.4%; P_{trend} =0.003).

Conclusions: Among cough-related office-based ambulatory care visits in the US, antitussive containing hydrocodone prescribing substantially decreased from 2003 to 2016, while gabapentinoid prescribing quadrupled.

4448 | Trends in consumption of psychiatric drugs among patients attended in primary healthcare in Brazil: An ecological time-series study

Julia RasoFerreira de Oliveira[1], Iahel Manonde Lima Ferreira[1], Marcela Jirón Aliste[2], Manuela Roque Siani-Morello[1], Fabiana Rossi Varallo[1] and Leonardo RegisLeira Pereira[1]
[1]*School of Pharmaceutical Sciences of Ribeirão Preto, University of Sao Paulo, Ribeirão Preto, Brazil;* [2]*School of Pharmaceutical Sciences, Universidad de Chile, Santiago, Chile*

Background: Trends in consumption of psychiatric drugs may be a tool to screening adverse drug reactions. The monitoring contributes for patient safety and appropriate use.

Objectives: Characterize the consumption of psychiatric drugs among patients attended in primary healthcare of Ribeirão Preto -São Paulo (Brazil).

Methods: Design: An ecological time series analysis was carried out from 2008 to 2012 to analyze the electronic registration of dispensing of essential psychiatric drugs. Setting: Electronic database contains registries of drugs dispensing for all patients attended in public healthcare facilities. During the period of the study. The municipality had, on average, 591.602 inhabitants. Exposures: All patients who had at least one registry of psychiatric drug dispensing from any primary health unit of Ribeirão Preto were eligible. Main outcome measures: Defined Daily Dose/1,000 inhabitants-day (DDD/1,000PD) and prescribed daily dose (PDD). The variables extracted were psychiatric drug, amount dispensing, sex and age of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients [pediatrics (0-19 years old); adults (20-59 years old) and elderly (above 60 years old)]. Statistical analysis: The Mann-Whitney test was applied to compare the population growth rate with the rate of consumption of psychiatric drugs. To verify the correlation between increasing age and the use of drugs, simple linear regression was performed.

Results: There were 1,577,241 patients with at least one registry of drug dispensation, of those 287,356 (18.2%) used psychiatric(s) drug(s). The majority were female [203,094/287,356 (70.7%)] and adults [185,929/287,356 (64.7%)]. There was an increase in the total consumption of psychiatric drugs. PDDs of lithium carbonate, fluoxetine, haloperidol, naltrexone, nitrazepam phenobarbital, and sertraline were higher than DDD assigned by World Health Organization. Only the consumption rates of sertraline (p=0,0304) and clonazepam (p=0,0304) were higher than population growth rate. There was a correlation with advancing age and consumption.

Conclusions: One out of five inhabitants of Ribeirão Preto consumes psychiatric drugs, being most women. Trends in consumption are related to population growth rate, except for sertraline and clonazepam. Despite of the discrepancies among DDD/1,000PD and PDD, the monitoring of consumption with these metrics may be a strategy to screening patients eligible for pharmaceutical care to early detect drug-related problems.

4451 | Recent trends in first-line glucose-lowering treatment choice for type 2 diabetes in younger and older adults in the U.S.

Hojin Shin[1,2], Sebastian Schneeweiss[2], Robert Glynn[2] and Elisabetta Patorno[2]

[1]Harvard T.H. Chan School of Public Health, Boston, MA; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Background: Although metformin is the accepted first-line treatment for type 2 diabetes (T2D), antidiabetic drugs that have demonstrated cardiovascular benefits in recent clinical trials, i.e., GLP-1 receptor agonists (GLP-1RA) and SGLT2 inhibitors (SGLT2i), could be increasingly considered as a first-line treatment, in particular for patients with cardiovascular disease (CVD).

Objectives: To evaluate recent trends in first-line glucose-lowering treatment choice for T2D among patients aged ≤65 versus >65, and to assess the impact of CVD on the initial treatment choice.

Methods: Using claims from two US commercial insurance databases (Optum Clinformatics and IBM MarketScan) and Medicare fee-for-service, we identified T2D patients aged ≥ 18 years (>65 in Medicare), who initiated any antidiabetic treatment from 1/2013 through 12/2017. We restricted to patients without any diabetes treatment in the prior 365 days (or more, depending on data availability). Patients were categorized by the class of their first antidiabetic drug prescription fill within age strata (≤65 versus >65), and results were pooled across databases. Trends in first-line T2D treatment initiation were plotted overall and stratified by baseline CVD and tested by the Cox and Stuart Trend test.

Results: Overall, we identified 409,546 T2D first-line initiators aged ≤65 and 427,483 initiators aged >65. Metformin was the most frequently initiated treatment with increasing trends from 1Q-2013 to 4Q-2017 (adults ≤65: 82.0% to 86.2% (P=.014), adults >65: 69.7% to 79.3% (P=.014)), followed by sulfonylureas, though with decreasing trends (adults ≤65: 6.9% to 3.9% (P=.014), adults >65: 14.4% to 8.6% (P=.014)). Compared to patients ≤65, patients >65 had lower metformin use (79.3% vs 86.2%) but higher sulfonylurea use (8.6% vs 3.9%), at the most recent assessment, i.e., Q4-2017. The initiation of GLP-1RA and SGLT2i increased over time, though their uptake remained low (for GLP-1RA, adults ≤65: 1.3% to 2.9% (P=.014), adults >65: 0.6% to 1.1% (P=.014); for SGLT2i, adults ≤65: 0.3% to 1.1% (P=.289), adults >65: 0.04% to 1.0% (P=.008)). In both age groups, patients with CVD were less likely to initiate metformin but more likely to initiate sulfonylureas, compared to patients without CVD; the uptake of GLP-1RA and SGLT2i did not differ by CVD.

Conclusions: Metformin was the most frequently initiated first-line treatment for T2D, consistent with current treatment guidelines, though sulfonylureas remained frequent among patients aged >65 or with baseline CVD. The uptake of GLP1-RA and SGLT2 inhibitors was low and did not differ by baseline CVD.

4487 | In-hospital post-operative analgesic use in patients undergoing primary total hip or knee replacement: A drug utilization study within the capital region of Denmark

Astrid Blicher Schelde[1], Anne Mette Skov Sørensen[1], Martin Erik Nyeland[1], Anders Odgaard[2] and Espen Jimenez-Solem[1,3]

[1]Department of Clinical Pharmacology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen, Denmark; [2]Department of Orthopaedic Surgery, Copenhagen University Hospital, Herlev and Gentofte, Copenhagen, Denmark; [3]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Background: Total hip and knee replacement (THR and TKR) are common surgical procedures associated with post-operative pain, which can be managed with post-operative analgesics. The in-hospital post-operative analgesic use in THR and TKR patients has to our knowledge not previously been examined in a large Danish setting. This is though important in order to identify patients at risk of potentially inappropriate pharmacotherapy and to ensure rational pharmacotherapy.

Objectives: To explore the pharmacological in-hospital post-operative analgesic use in patients undergoing primary THR and TKR.

Methods: The cohort included all patients with a primary THR or TKR in the Capital Region of Denmark, January 2012 to December 2015. Using a regionwide registry based on electronic health records, we obtained information on patient characteristics and in-hospital post-operative analgesic use, including paracetamol, Non-Steroidal Anti-Inflammatory Drugs (NSAIDs), opioids, and gabapentinoids. For each surgical procedure (THR and TKR), we calculated the prevalence of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients having each of these analgesic drugs prescribed and administered during their post-operative in-hospital stay.

Results: We identified a total of 15,164 patients having a primary THR (n=7,724, mean age=69 years, 39% males) or TKR (n=7,440, mean age=68 years, 38% males) performed during the study period. The prevalence of THR and TKR patients having post-operative analgesics administered in-hospital was 99.1% and 99.0% for paracetamol, 24.5% and 72.7% for NSAIDs, 43.6% and 76.0% for opioids, and 50.1% and 58.9% for gabapentinoids, respectively.

Conclusions: We observed differences in the in-hospital use of NSAIDs and opioids between THR and TKR patients. It is of note that half of all patients were administered gabapentinoids. The results call for studies analyzing whether these treatment patterns raise any short- and long-term safety concerns for the patients.

4488 | Patterns of triptan use by gender in tuscany region, Italy

Giulia Hyeraci[1], Rosa Gini[1], Silvia Benemei[2], Francesco De Cesaris[2], Chiara Lupi[2], Pierangelo Geppetti[2] and Giuseppe Roberto[1]
[1]*Regional Agency for Healthcare Services of Tuscany, Florence, Italy;* [2]*Headache Centre, Careggi University Hospital, Department of Health Sciences, University of Florence, Florence, Italy*

Background: Triptans are the most commonly used anti-migraine drugs in clinical practice. However, the potential increased risk of acute cardiovascular events (ACE) related to their vasoconstrictive effect, and the possible occurrence of medication overuse headache (MOH) secondary to an excessive triptan intake, represent the main limitations to their use. Although triptan utilization has been extensively investigated, evidence on the influence of gender on their patterns of use in clinical practice is still poor.

Objectives: To describe the patterns of triptan utilization by gender in the general population of Tuscany, Italy, in 2017.

Methods: The population-based regional administrative database of Tuscany was used. For each subject active into the database at 1 January 2017, demographic information were linked to hospital discharge records and outpatient drugs dispensings. Prevalent triptan users (PU) were subject ≥1 dispensing during 2017. PU with no dispensing before 2017 were new users (NU). Prevalence and incidence of use by age classes were observed. Utilization patterns were categorized as: sporadic (1 dosage unit), occasional (≥1 dosage unit with ≤3 months between 2 dispensings), regular (≥1 dosage unit with ≥3 months between 2 dispensings), and overuse (≥20 dosage units per month for ≥3 consecutive months). Users with prior ACE were identified. All analyses were stratified by gender.

Results: PU were a total of 4109 men and 15400 women, of which NU were 37.7% in men and 29.9% in women. Prevalence (2.1%) and incidence (0.6%) of use showed a peak between 45 and 54 years and 35-44 years, respectively, in both sexes. Elderly users accounted for 1.1% of PU users and 0.39% of NU. The percentage of patients with previous ACE was 7.6% in NU and 5.5% in PU. NU with ACE were 5.5% in men and 2.1% in women. Among NU, sporadic (67.3% vs 63.6%) and occasional (11.7% vs 8.6%) use was slightly higher in men while regular use was more frequent in women (21.0% vs 27.7%). Overusers were 0.1% among NU in both genders, while among PU they were 2.1% of men and 1.5% of women.

Conclusions: Women used triptans more regularly than men. Overusers possibly affected by MOH increased after first year of treatment in both genders. The non-negligible use of triptans in non-recommended populations like elderly and patients with previous ACE warrants analytical studies on triptan safety.

4510 | Trends in truvada (emtricitabine and tenofovir) utilization among HIV positive and HIV negative persons in the U.S. 2011 - 2016

Carter McCormick and Dima Qato
University of Illinois at Chicago, Chicago, IL

Background: Despite its importance in HIV treatment and prevention, there is limited information on trends in Truvada utilization overall and since FDA approval for pre-exposure prophylaxis (PrEP) in HIV-patients.

Objectives: To describe the trends of Truvada usage in the United States from 2011 - 2016.

Methods: This descriptive observational study used a nationally representative sample from IQVIAs LifeLink (LRx) data from 2011 - 2016. Patients using Truvada without the use of another HIV medication were included as HIV- PrEP users and all other Truvada users concurrently using another HIV medication were included as HIV+ treatment users. We examine the share of users overall and by age and gender.

Results: Overall, the percent of HIV+ persons using Truvada decreased from 94% to 61%, and this decrease was most pronounced in men ages 45-49 (19%-8.5%). Among Truvada users, the share of HIV+ users has declined while the share of HIV negative users increased from 6% to 39%. Men are have the most pronounced increase, from 3% to 36%. Women during this time consistently remained between 2 - 3%. When HIV- users are broken into age groups, men age 25 - 39 (2% - 21%) have profound increases while men 24 years and younger have more minimal increases (0.2% to 3.2%). Women across all age groups see minimal to no change, consistently remaining under 1%.

Conclusions: These findings indicate the use of Truvada is increasingly being used as PrEP in HIV-persons. Older men are the group driving the increase in utilization for PrEP, while young men and pediatric users have much lower increases in utilization. In contrast to men, women's use of Truvada, especially among young women, has not changed during this time. With young women and men being at higher risk for HIV, it is important to address these age and gender disparity through targeted interventions and policies to increase utilization among these important risk groups.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

4528 | Trends in buprenorphine prescribing among medicare part D providers, 2013-2017

Kristin Shiue[1,2], Mary Figgatt[1,2] and Yvonne Golightly[1,3]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: While opioid prescribing has recently declined in the United States, prescription opioid overdose rates have increased among adults >65 years of age. To treat opioid use disorder, there has been significant uptake of buprenorphine nationwide, particularly after the publication of *SAMHSA Federal Guidelines for Opioid Treatment Programs* in 2015. Buprenorphine is covered under Medicare Part D, but little is known about prescribing patterns in Part D beneficiaries, most of whom are older adults.

Objectives: Characterize trends in buprenorphine prescribing among Medicare Part D providers over time, by prescriber specialty, and by state.

Methods: Data from the Medicare Part D Prescriber Public Use Files for 2013-2017 were used for descriptive analyses (n=1404428 unique providers). Providers with >10 claims for buprenorphine were classified as buprenorphine prescribers, with prescribing assessed among all providers, as well as specifically among opioid prescribers (defined as providers with >10 claims for any opioids).

Results: Buprenorphine prescribing increased steadily from 2013-2017, with the number of Part D providers nearly doubling from approximately 9000 to more than 16000 per year. Among opioid prescribers in 2017, <2% were buprenorphine prescribers, of which the majority (75%) had ≤10 beneficiaries receiving buprenorphine. Buprenorphine prescribers were primarily in family practice (25%) and internal medicine (16%), though the percent of providers prescribing buprenorphine within these specialties remained relatively low over time (1%-4%). Neuropsychiatry, pain management, psychiatry, and anesthesiology had the greatest increases in buprenorphine prescribers from 2013-2017 (10% to 13% absolute increase among providers who were opioid prescribers), with pain management and anesthesiology as the top specialties in 2017 with regard to percent of all providers that were buprenorphine prescribers (30% and 11%, respectively). The percent of providers prescribing buprenorphine varied between <1% to 5% during the study, with the greatest increases observed in Maine, Vermont, and West Virginia (1% to 2% absolute change among all providers).

Conclusions: Despite the growing number of buprenorphine prescribers from 2013-2017, the overall proportion of providers regularly prescribing buprenorphine to Medicare Part D beneficiaries remains low. To mitigate a further increase in prescription opioid overdose rates among older adults, further exploration of specialty and state-level differences among Part D providers is warranted to guide efforts to encourage buprenorphine use in this population.

4553 | Sex differences in patterns of systemic agents' use among individuals with psoriasis

Raymond Milan[1], Jacques LeLorier[2], Ivan Litvinov[1] and Elham Rahme[1]
[1]McGill University, Montreal, QC, Canada; [2]Université de Montréal, Montreal, QC, Canada

Background: Psoriasis severity differs between males and females. However, it is not clear if psoriasis management also differs by sex. Severe psoriasis is treated with conventional systemic agents (CSA) and/or biologic agents when CSA are ineffective or inappropriate.

Objectives: We assessed sex differences in the utilization patterns of CSA and switches to biologic agents among individuals with psoriasis.

Methods: We conducted a retrospective cohort study using Quebec health administrative databases (1997 - 2015). Individuals ages ≥ 20 years were included if they received a first psoriasis diagnosis and at least one CSA. Individuals were followed for two years. For each treatment claim, a 60-day grace period between the end of the supply period of the last prescription fill and the beginning of a new prescription fill was considered. Treatment switch occurred when a patient filled a prescription for a different CSA or a biologic agent during the supply or grace period of the initial CSA. Treatment discontinuation occurred when the patient did not have a supply for any systemic agent for a period exceeding 60 days. Analyses were stratified by sex. Multivariate Cox proportional hazard models were conducted to determine the risk of switch to a biologic agent. Multinomial logistic regression models were conducted to identify predictors of treatment switch and discontinuation.

Results: We included 1,272 individuals with psoriasis (55% females). Most individuals were initiated on methotrexate (MTX, 56%), followed by acitretin (37%). During the follow-up, 364 (29%) were persistent, 688 (54%) discontinued and 220 (17%) switched (75% to another CSA and 25% to a biologic agent). Most patients switching to a biologic agent received adalimumab (41%) and infliximab (27%). Compared to females, males tended to switch more to a biologic agent (44/1000 person-years vs 27/1000 person-years, HR=1.66, 95% CI: 0.96-3.03). When compared to persistent patients, males and females who switched were more likely to be younger and initiated on acitretin and sulfasalazine (vs MTX). Initiating on these agents was also associated with treatment discontinuation among male, but not among female individuals. Males with psoriatic arthritis and females with rheumatoid arthritis were less likely to discontinue their initial CSA (OR=0.49, 95% CI: 0.26-0.90 and 0.40, 0.21-0.71 respectively).

Conclusions: MTX was the CSA treatment of choice for both sexes in the management of psoriasis. Persistence on CSA was lower among males and younger psoriasis patients, and higher among those with other inflammatory diseases.

4560 | Injectable paliperidone palmitate showed a higher adherence rate compared to oral atypical antipsychotics in Japan

Ting Zhang[1], Hsingwen Chung[2], Tao Wu[1], Yongjing Zhang[3], Yanfang Liu[4] and Hong Qiu[2]
[1]*Janssen Research and Development, China, Beijing, China;* [2]*Janssen Research and Development, USA, Titusville, NJ;* [3]*Janssen Research and Development, China, Shanghai, China;* [4]*Janssen Research and Development, Singapore, Singapore, Singapore*

Background: Long acting injectable paliperidone palmitate (PP1M) may improve adherence in schizophrenia patients.
Objectives: To compare persistence and adherence of PP1M vs oral atypical antipsychotics (OAAs) for schizophrenia treatment in Japan.
Methods: This was a retrospective cohort study utilizing the Japanese Medical Data Center (JMDC) claims database. The study period was between 2013 and 2018. The overall cohort included patients who were a) diagnosed with schizophrenia, b) with at least one prescription of PP1M or OAAs, c) with continuous care (≥ 3 consecutive visits with at least 7 days in-between visits and no gap > 45 days), and d) ≥ 18 years old. The index date was defined as the date of the first prescription of PP1M or any OAAs. The study cohort included all PP1M patients and 1:1 matched OAAs patients using a propensity score, which was created using baseline characteristics including age, gender, diagnosis, medication usage, and hospital visits. Persistence and adherence were compared between the PP1M and OAAs groups. Persistence was defined as days to first discontinuation (a gap between two consecutive PP1M or OAAs prescriptions ≥ 45 days) plus 28 days (as days' supply of the prescribed drug) within 1-year post-index. A Cox proportional hazards model was used to estimate the hazard ratio (HR) for 1-year persistence. Adherence was assessed by the proportion of days covered (PDC), which was calculated as the number of non-overlapping days covered by PP1M or OAAs divided by total days up to 1-year post-index or first discontinuation, if it happened. Patients with PDC ≥ 80% were considered adherent. A logistic regression model was used to estimate the odds ratio (OR) for adherence.
Results: There were 249 patients in the PP1M group and 40,058 patients in the OAAs group overall. After propensity score matching, 249 patients in OAAs group were matched. In the PP1M group, mean (SD) age was 39.5 (11.4) years, and 39.8% (99 patients) were males. The mean (SD) persistence of the PP1M group was 235.0 (139.2) days; in the matched OAAs group, the corresponding result was 197.6 (151.6) days. PP1M was associated with better persistence, with 21% lower risk of discontinuation compared to OAAs (adjusted HR=0.79, 95% CI=0.66-0.95). 66% of patients in the PP1M group were adherent as indicated by PDC, while 54% patients in the matched OAAs group were adherent. PP1M was associated with better adherence, adjusted OR=1.66 (95% CI=1.14-2.42).
Conclusions: Overall, persistence and adherence of PP1M and OAAs in Japanese schizophrenia patients were high, and persistence and adherence of PP1M were better than OAAs in Japan.

4593 | Influencing factors for medications in patients with stroke in a nationally representative sample of older Chinese: Results from CHARLS

Jingnan Feng, Shengfeng Wang and Siyan Zhan
Peking University, Beijing, China

Background: Stroke is the first cause of death among Chinese residents, effective medication after stroke can reduce the functional disability and complications in patients. Thus, accelerate the rehabilitation process and save social resources.
Objectives: To explore the medication rate and its influencing factors in the elderly stroke population in China.
Methods: Data were collected from China Health and Retirement Longitudinal Study (CHARLS) over the period from 2011 to 2015. We analyzed the prevalence of stroke and drug treatment and compared demographic, health status and functioning data between non- medication and medication groups. Influencing factors were estimated by using Logistic regression.
Results: In 2015, a total of 10,162 participants aged 60 years and older were included in this study. The prevalence of stroke slightly increased from 3.57% to 4.91%. As for medication for stroke, more than 28.21% patients didn't take any treatments in the 5 years. Although western medicine was the preferred medication (over 50%), the percentage of patients using Chinese traditional medicine and acupuncture increased by 2% between 2011 and 2015. Compared with medication group, non- medication group showed higher proportion of smoking and memory-related diseases (P<0.05). Logistic regression analysis showed that the major risk factors included drinking (OR=1.46,95%CI:1.02-2.08) and memory-related diseases (OR=1.71,95%CI:1.20-2.45), while heart attack (OR=0.29,95% CI:0.12-0.74) was the protective factor.
Conclusions: As the prevalence of stroke increased, the proportion of taking medication in elderly stroke patients was relatively low in China. Intervention and education should be strengthened for patients without medication, special attention needs to be paid on patients with multiple comorbidities and unhealthy lifestyles.

4610 | Differential prescription patterns of drospirenone-containing combined oral contraceptives in Eastern Europe and North America: Insights from the INAS-FOCUS Study

Clare Barnett, Thai Do Minh, Suzanne Reed and Klaas Heinemann
ZEG Berlin, Berlin, Germany

Background: Combined oral contraceptives (COCs) are a commonly prescribed method of birth control in North America and Eastern Europe; prescription practices and user populations are considered to be homogenous across continents. Using baseline data from the INAS-FOCUS study, we explored whether the drug utilization patterns were similar in North America and Eastern Europe and why differences seen, if any, might exist.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Objectives: To describe differences in prescription patterns and user demographics in an all-comer, observational, active-surveillance registry.

Methods: Large, prospective, controlled, non-interventional, long-term cohort registry following users of DRSP/EE+ and oCOC for up to seven years. The registry did not interfere with the physicians' prescribing behavior and no medical inclusion/exclusion criteria were applied. Participants were recruited via a network of COC-prescribing physicians in Russia, Ukraine, Canada and the United States of America (US). Demographics, medical and gynecological history were collected at baseline. Follow-up included collection of contraceptive utilization history and identification of adverse events every 6-12 months via an active surveillance approach employing self-administered questionnaires. Patient-reported clinical outcomes of interest were validated via health care professionals.

Results: The registry included 82,780 women, comprising 7,649 users of DRSP/EE+, 13,034 users of DRSP/EE- (DRSP/EE without folate) and 62,098 users of oCOC-. Prescription patterns in eastern Europe showed little overlap with North America. In Russia/Ukraine, DRSP/EE+ users comprised 17.4% of the baseline study population, compared to only 4.1% in the US/Canada. North American study participants tended to be prescribed COCs containing Norethindrone (NETA)- (47.0%), Norgestimate (NGM)- (20.5%) and Levonorgestrel (LNG)- (8.3%), whereas the most commonly prescribed progestogens in eastern Europe were DRSP (53.7%), oCOC (44.5%, mostly DNG) and LNG- (1.8%).

Conclusions: INAS-FOCUS was a long-term, active surveillance registry based on primary data collection methods. Results showed a large discrepancy in COC utilization patterns between eastern Europe and North America; despite LNG being recommended as first-line therapy, only 8.3% of North American study participants and 1.8% of eastern European study participants were prescribed an LNG-containing COC. NETA, NGM (North America) and DRSP (eastern Europe) were more commonly prescribed.

4631 | Nationwide patterns of long-term ranitidine use and its associated factors in Korea

Myo-Song Kim[1], Seung-Hun You[1], Min-Taek Lee[1], Ye-Jin Kang[1], Ye-Jee Kim[2], Joongyub Lee[3] and Sun-Young Jung[1]

[1]*College of Pharmacy, Chung-Ang University, Seoul, Republic of Korea;* [2]*Asan Medical Center, Seoul, Republic of Korea;* [3]*Inha University Hospital, Incheon, Republic of Korea*

Background: Ranitidine, a histamine H2-receptor antagonist, has recently been recalled due to contamination with N-nitroso-dimethylamine. Because ranitidine is used for both for treatment of gastrointestinal disorders and for gastroprotection in long-term NSAIDs use in some chronic diseases, it is necessary to identify the nationwide patterns of long-term use.

Objectives: To assess patterns of long-term ranitidine use and factors affecting the long-term prescribing in the Korean population.

Methods: We analyzed prescribing patterns of ranitidine and characteristics of long-term users using Korea Health Insurance Review and Assessment database between 2007 and 2018. We calculated the annual number of patients who received ranitidine, and each patient's total prescription days and doses for 12 years. Long-term prescription was defined as prescription for more than 365 days considering the distribution of total prescription days in study population. We identified patient's comorbid status including upper gastrointestinal (UGI) disease (ICD-10, K20-K31), rheumatic diseases (M05.x, M06.x, M31.5, M32.x-M34.x, M35.1, M35.3, M36.0), or musculoskeletal diseases (M07-M99 except for the codes included in rheumatic diseases). We categorized patients' type of insurance as medical insurance, medical aid, and veterans. We applied multivariable logistic regression model to examine factors associated with long-term prescription of ranitidine.

Results: A total of 42,311,376 patients received ranitidine prescription between 2007 and 2018 in Korea (51.8% female; mean age 41.7 (±19.1) years), which accounting for approximately 82% of the Korean population. The number of patients has increased steadily from 5,466,816 in 2007 to 19,571,060 in 2018. Of these, 2,300,403 (5.4%) were long-term users. In the multivariable analysis, increased age (OR=1.822; 95% CI 1.820-1.824, 10-year increments), comorbid rheumatic disease (OR=4.37; 95% CI 4.34-4.40), UGI disease (OR=3.54; 95% CI 3.53-3.56), musculoskeletal diseases (OR=2.85; 95% CI 2.84-2.86), medical aid (OR=2.79; 95% CI 2.78-2.81), and veterans (OR=4.45; 95% CI 4.28-4.61) were associated with long-term prescription of ranitidine.

Conclusions: Long-term prescription of ranitidine was associated with increased age, socioeconomic status, and specific comorbidities of patients. Patient characteristics associated with the long-term prescription of ranitidine could aid identifying at-risk patients, and provide information for designing further research assessing cancer risk associated with chronic exposure to ranitidine.

4642 | Overall quality of antibiotic consumption in a middle-income developing country over 16 Years

Maryam Taghizadeh-Ghehi[1], Fatemeh Rezaei[1], Aarefeh Jafarzadeh-Kohneloo[2] and Mona Kargar[1]

[1]*Research Center for Rational Use of Drugs, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran;* [2]*Department of Epidemiology and Biostatistics, Faculty of Health, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran*

Background: Resistance to antibiotics is a global health challenge that mainly resulted from inappropriate antibiotic use. A comprehensive picture from quantity and quality of antibiotic consumption at national level would be necessary to detect irrational use and overcome consequent problems.

Objectives: Our aim was to study trend and pattern of antibiotic consumption considering WHO Access, Watch, Reserve ("AWaRe") categories of antibacterials, over 16 years in Iran.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: 1. Design: This cross-sectional observational study was conducted using data recorded from 2000 to 2016.2. Setting: National pharmaceutical wholesale data in Iran were used.3. Exposures: In according to WHO ATC/DDD system (2018), systemic antibacterial agents in J01 group were targeted. Consumption data of antibiotics were extracted, cleaned, and converted into WHO defined daily doses (DDDs).4. Main outcome measures: DDDs per 1000 inhabitant per day (DID)) was calculated annually for every single antibiotic and summed up for WHO AWaRe categories (2019). Antibiotics from AWaRe categories constituted 90% of consumption (DU-90%) were also determined. Statistical Analysis: Joinpoint regression (Joinpoint, version 4.7.0.0) was used to analyze the trends.

Results: Antibiotic consumption increased over 16 years (β=1.28, P-value=0.000). The share of "Access" antibiotics from annual consumption decreased from 92.63% in 2000 to 59.76% in 2016. However, net DIDs of the "Access" antibiotics did not change significantly (P-value=0.49). Amoxicillin was the most commonly used antibiotic, with DIDs of 45.22 in 2000 and 32.74 in 2016. Consumption of antibiotics in "Watch" category increased significantly (β=1.34, P-value=0.000). The share of "Watch" antibiotics from annual consumption increased from 7.36% in 2000 to 40.22% in 2016. DU-90% comprised median (Min-Max) 9 (8-10) antibiotics. Among nine and 8 DU-90% antibiotics in 2000 and 2016, none and 3 medications were from "Watch" category, respectively. Cefixime, ciprofloxacin, and azithromycin were consistent representatives of "Watch" category among DU-90% antibiotics from 2006 onwards and cefixime remained at the second place of annual antibiotic use in our country, since 2007.

Conclusions: Systemic antibacterial use have increased significantly during past decades in Iran. Although the "Access" antibiotics are still comprised nearly 60% of total antibiotic consumption in our country, high amount of antibiotic consumption, ascending trend and gradual shift of use to "Watch" agents could ring the bells for health policy-makers in our country.

4643 | Increasing tramadol utilisation under strict regulations for opioid prescribing: A Cross-sectional study in Taiwan

Teng-Chou Chen[1], Ting-Chun Wang[2], Chih-Peng Lin[3], Kerina Bonar[4], Darren M. Ashcroft[1,5,6], K. Arnold Chan[2] and Li-Chia Chen[1]

[1]Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom; [2]Health Data Research Center, National Taiwan University, Taipei, Taiwan; [3]Department of Anesthesiology, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan; [4]Mundipharma Research Limited, Cambridge, United Kingdom; [5]NIHR Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom; [6]NIHR Greater Manchester Patient Safety Translational Research Centre, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom

Background: Tramadol has been classified as a controlled medicine in several countries due to safety concerns and rising utilisation. Although opioid prescribing to patients with non-cancer pain is strictly regulated in Taiwan, tramadol is not included in the controlled regulation for chronic opioid prescribing.

Objectives: This study aims to identify the utilisation trend of prescription tramadol and other opioid analgesics and investigate the influence of drug regulation on opioids prescribed for managing cancer or non-cancer pain in Taiwan.

Methods: This cross-sectional study used the Taiwan National Health Insurance claims records and the Taiwan cancer registry from 2001 to 2016. Opioid analgesics commonly prescribed for pain relief were identified from prescribing records from outpatient clinic visits, emergency department visits or during inpatient hospitalisations. The annual number of adult opioid users, annual opioid utilisation (Defined Daily Doses [DDDs]/1000 registrants) and the number of supply days were enumerated for each calendar year and further stratified into cancer and non-cancer patients. Descriptive statistics were used to report the trend of outcome measures in each calendar year.

Results: Overall, the annual number of opioids users increased from 606,457 to 1,226,935, and 7,551,250 opioid users were identified between 2002 and 2016. There was a marked increase in the annual opioid utilisation (55.6 to 578.1 DDD/1000 registrants) and mean supply days (from 6.4±14.5 to 28.7±57.9 days) from 2002 to 2016. Taiwan regulations strictly limited chronic opioids prescribed to patients with non-cancer pain, of which only a small proportion of non-cancer fentanyl (20%) and morphine users (<2%) were prescribed with an annual number of supply days greater than 28 days. The annual utilisation of morphine (6.4 to 53.5 vs. 1.1 to 9.6 DDD/1000 registrants) and fentanyl (8.3 to 37.0 vs. 0.16 to 1.8 DDD/1000 registrants) to patients with cancer was consistently higher than patients without cancer. However, in contrast to morphine and fentanyl, the utilisation of tramadol prescribed to patients without cancer increased 92.2-fold (3.7 to 341.2 DDD/1000 registrants) from 2002 to 2016.

Conclusions: Opioid utilisation increased ten-fold due to the increasing number of opioid users and chronic prescribing of tramadol to patients with non-cancer pain. The strict regulation of prescribing potent opioids for patients with non-cancer pain may result in sub-optimal pain management, and the prominent substitution of tramadol for other opioids also raises safety concerns in Taiwan.

4649 | Adherence and persistence of once versus twice-daily direct oral anticoagulants

Claudia Bartolini[1], Rosa Gini[1], Tania Schink[2], Elisabeth Smith[3], Eline Houben[3], Fernie JA Penning- van Beest[3], Georgios Spentzouris[4] and Ron MC Herings[3]

[1]Agenzia regionale di sanità della Toscana, Florence, Italy; [2]Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany; [3]PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands; [4]Daiichi Sankyo Europe GmbH, Munich, Germany

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Direct oral anticoagulants (DOACs) are available for atrial fibrillation (AF) patients as once-daily (QD) (edoxaban and rivaroxaban) or twice-daily (BID) (apixaban and dabigatran) regimens.
Objectives: To compare adherence and persistence of QD vs. BID dosage regimens (DR) in AF patients.
Methods: A cohort study was conducted in 3 databases in Germany (DE), Italy (IT) and the Netherlands (NL). AF patients starting DOACs between approval date and 2018 were included. The index date (ID) was the date of first dispensing. We restricted to patients aged ≥18, ≥1 year database history and ≥1 year follow-up. Adherence to treatment was defined over the first year of follow-up based on the proportion of days covered≥80% during the exposure period. The exposure period was defined as the number of days between ID and date of the last drug dispensing with the index DR in the first year of follow-up. Persistence at one year was defined as absence of a gap between dispensings of the index DR before the end of the first treatment year. The gap was defined as half the duration of the previous dispensing, or 7 days if shorter. Switch between DRs was assessed during the whole exposure period from first to last dispensing in all available follow-up.
Results: 167,445, 32,260 and 6,068 patients were included from DE, IT and NL, respectively. 61%, 40% and 31% were QD users, respectively, and mean age among the two groups was the same in all sites (i.e. 74, 77 and 70 years respectively). Patients with a previous record of vitamin K antagonist treatment were 25%, 43% and 31%, respectively. Mean exposure period of QD/BID users was 23/21, 25/29 and 23/25 months, respectively. Among QD/BID users, patients with≥10 dispensings during the exposure period were 35/43%, 82/86% and 52/54%, respectively. Among QD/BID users, 82/62%, 89/88% and 94/91%, respectively were adherent during the first year. Persistence rates at one year in QD/BID users were 46/31%, 13/14% and 60/59%, respectively, but, based on high adherence, treatment discontinuation was temporary. During the exposure period, switches to the other DR occurred in 13/10%, 5/6% and 8/7% of QD/BID users in DE, IT and NL.
Conclusions: Adherence to treatment was high everywhere, and markedly higher in QD users compared to BID users in DE. Persistence was low, and markedly lower in BID users versus QD users in DE, but discontinuation was temporary. The comparison among sites was biased by different duration of a dispensing period, probably linked to differences in the local regulations regarding number of pills allowed in a single dispensing package, which is lower in IT. Switching between DRs was rare among both QD and BID users.

4651 | A Multidatabase study of trajectories of antidepressant use in Italy

Ippazio Cosimo Antonazzo[1], Olga Paoletti[2], Claudia Bartolini[2], Giuseppe Roberto[2], Valdo Ricca[3], Giovanni Castellini[3], Marco Menchetti[4], Elisabetta Poluzzi[5], Elisa Sangiorgi[6], Giampiero Mazzaglia[1] and Rosa Gini[2]

[1]Center for Public Health Research (CESP), University of Milan – Bicocca, Milan, Italy; [2]Epidemiology Unit, Regional Agency for Healthcare Services of Tuscany, Florence, Italy; [3]Psychiatric Unit, Department of Health Sciences, University of Florence, Florence, Italy; [4]Psychiatric Unit, Department of Biomedical and NeuroMotor Science (DIBINEM), University of Bologna, Bologna, Italy; [5]Pharmacology Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [6]AUSL di Bologna-Dipartimento Farmaceutico, Bologna, Italy

Background: Tuscany (TUS) is the Italian region with the highest consumption of antidepressants (AD): 62 Defined Daily Dose (DDD)/1000 inhabitants/day were recorded in 2018. In the neighboring region Emilia-Romagna (ER), similar to TUS in demographics, socio-economic conditions, and regional healthcare system, consumption in 2018 was 52 DDD/1000 inhabitants/day.
Objectives: To investigate reasons for observed difference in consumption, based on patterns of AD use.
Methods: An observational retrospective cohort study was carried out using administrative data from Florence (FLO) and Bologna (BO), two large, similar areas respectively from TUS and ER. All inhabitants with ≥1 AD pharmacy claim from 2009 to 2013 and without AD claims during the previous 5 years were selected and incidence rate of use (IR) was computed in FLO and BO as well as incidence ratio (IRR) between FLO and BO. Users with ≥5 years of follow-up were included in the next analysis. Gender, age and type of index AD (iAD) were observed. Twenty binary variables were defined, each indicating whether≥1 AD claim was recorded in the corresponding trimester (TRI). Trajectories were clustered and comparison of occurrence of clusters was conducted across area, gender, age and iAD.
Results: The study cohort included 219,393 individuals with ≥1 AD claim: 149,285 in FLO (IR: 2.12/100 person-years) and 70,108 in BO (IR: 1.92/100 person-years), with IRR 1.11 (CI 95%: 1.10-1.12). The majority of the 178,633 individuals with ≥5 years of follow-up were female (64%) and aged between 65 and 84 years (32%), but in FLO patients aged ≤45 were more common (30% vs 28%) and iAD were more commonly selective serotonin reuptake inhibitors (SSRi) (75% vs 72%). 6 clusters of trajectories were identified: (1) 38% were treated for 1 TRI only; (2) 12% had repeated short cycles (1 TRI); (3) 15% had ≥1 cycle of ≥2 after the first 1 TRI; (4) 9% had longer cycles during the first 2 years and then discontinued; (5) 18% had long cycles (between 8 and 19 TRI); and (6) 4% were continuously treated for 5 years. Clusters were distributed similarly across areas, although clusters 5 and 6 were slightly more common in FLO. Clusters 5 and 6 were also more frequent among older individuals and SSRIs users, and more so in FLO.
Conclusions: In FLO higher incidence of new AD users was observed, and slightly higher occurrence of younger patients and SSRi treatments. This may indicate a higher propension in FLO clinicians to prescribe AD for anxiety disorders, more prevalent among younger patients and more commonly treated with SSRi. Lower reluctance in FLO both to initiate and to withdraw from therapy may be due to higher acceptability of AD in the population.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4665 | Channelling bias of initiating fixed ratio combination (FRC) therapy in adults with type 2 diabetes (T2D): A retrospective observational US study

Robert Lubwama, Anders Boss, and Alka Shaunik
Sanofi, Bridgewater, NJ

Background: Channelling bias is a form of confounding that occurs when a drug is preferentially prescribed to patients with different baseline characteristics, and the observed response may not be related to the drug or cannot be generalised to patient populations. Early data on FRC (basal insulin + GLP-1 receptor agonist [GLP-1 RA]) use among people with T2D in the US indicate that channelling bias may be present.
Objectives: To investigate differences in baseline demographic and clinical characteristics in adults with T2D initiating FRCs (iGlarLixi or IDegLira) compared with those initiating GLP-1 RAs or sodium-glucose linked transporter-2 inhibitors (SGLT-2is).
Methods: Data from the US Optum Humedica electronic health records database were captured from January 1, 2017 to June 30, 2018. Adults with T2D initiating FRCs were compared with those initiating GLP-1 RAs and SGLT-2is. Baseline characteristics and clinical variables were extracted using ICD-9-CM/ICD-10-CM and prescription codes. Multivariate logistic regression analyses adjusting for age, sex, number of oral antidiabetic medications and comorbidities in the baseline period were used to estimate odds ratios (OR).
Results: The clinical profile of people initiating FRC treatment (n=3003) differed from those initiating therapy with GLP-1 RAs (n=49,935) and SGLT-2is (n=44,895). When compared with adults initiating GLP-1 RAs, those initiating FRCs were more likely to have a lower body mass index (≥35 kg/m^2; OR = 0.70, p<0.001), be older (age 55-64 years; OR = 1.24, p<0.001) or have serious hyperglycaemia (OR = 1.32, p<0.05) or HbA_{1c} ≥9 % (OR = 1.44, p<0.001). When compared with adults initiating SGLT-2i, those initiating FRCs were less likely to be male (OR 0.73, p<0.01), or more likely to have HbA_{1c} ≥9 % (OR 1.87, p<0.001), serious hyperglycaemia (OR = 1.81, p<0.01), nephropathy (OR = 1.61, p<0.001) or neuropathy (OR = 1.29, p<0.05). When reviewed by the prescribing physician, FRC prescriptions were more likely than GLP-1 RA prescriptions to be written by specialists (OR = 1.50, p<0.001).
Conclusions: The differences observed between the baseline characteristics of adults initiating FRCs and those initiating GLP-1 RAs and SGLT-2is are prognostic factors and confounders for diabetes therapy response and may influence short- and long-term disease outcomes. Therefore, it is important to apply appropriate statistical methods to control for the confounding in comparative-effectiveness observational studies when analysing data from electronic medical or claims databases for people initiating FRC therapies.

4680 | Trend and contributing factors of prescribing antidepressants in primary care in England: 2013-2019

Xinchun Gu, Tehreem Fatima Ahmed, Teng-Chou Chen, Douglas Steinke and Li-Chia Chen
Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom

Background: Patients with chronic pain were commonly prescribed with antidepressants and opioids in primary care settings in England. The increase of antidepressants prescribed in primary care ascribes to multiple factors, e.g. socioeconomic status (SES) or strategies for deprescribing opioids, but the trend in utilisation and the associated factors have not been fully studied.
Objectives: This study aimed to categorise the trend of antidepressants prescribed in primary care in England and assess factors associated with the prescribing.
Methods: This cross-sectional study used monthly practice-level prescribing data and publicly available statistics in England from the United Kingdom National Health Service Digital and Office for National Statistics between April 2013 and March 2019. Antidepressants were categorised into selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs), monoamine oxidase inhibitors (MAOIs) and others based on the British National Formulary. The annual and quarterly utilisation of antidepressants were measured by Defined Daily Dose (DDD)/1000 registrants. Practices were grouped by a trajectory model analysing their quarterly utilisation between April 2013 and March 2019. Multilevel mixed-effect regression was used to assess the association between one-year utilisation (April 2018 to March 2019) and contributing factors (i.e. demographic characteristics, prevalences of diseases, and SES) after adjusting the cluster-effect of Clinical Commissioning Groups.
Results: The annual utilisation of antidepressants increased from 29484 to 39723 DDD/1000 registrants from 2013 to 2019. Of the five antidepressant categories, SSRIs had the largest increase from 20522 to 28272 DDD/1000 registrants, while the annual utilisation of TCA and MAOIs decreased slightly. Of the 5 utilisation trajectories identified from 8054 general practices, only one (16.9% practices) presented a decreasing utilisation. The greater annual utilisation was associated with a higher proportion of female, elderly, mental health illness, palliative care, depression, smoking, obesity and deprived SES in a practice.
Conclusions: Most practices in England increasingly prescribed antidepressants in the recent 6 years, and the rising utilisation was dominated by the increasing prescribing of SSRIs. SES was one of the factors ascribe to antidepressant utilisation. Further study is needed to identify social determinants and potential harms of the increased antidepressant prescribing.

4681 | Trends in nationwide metamizole utilization in Turkey

Caner Vizdiklar, Volkan Aydin and Ahmet Akici
Marmara University School of Medicine, Istanbul, Turkey

Background: Use of metamizole (dipyrone) is controversial, especially due to serious adverse events, which is more pronounced for use in

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

outpatient setting and via parenteral route. While the drug has been withdrawn or unapproved in several countries, it is still in use in some countries including Turkey.

Objectives: This study aimed to evaluate nine-year nationwide metamizole consumption trend in Turkey.

Methods: In this retrospective descriptive study, we obtained nationwide metamizole consumption data between 2010 and 2018 from IQVIA Turkey. Drug utilization was measured by DDD (defined daily dose)/1000 inhabitants/day (DID) unit.

Results: Overall metamizole utilization decreased from 1.13 to 0.94 DID during the study period. Enteral route (71.2-86.6%) and outpatient setting (87.6-95%) were mostly preferred. Percentage of enteral preparations raised from 78.1% to 83.6%, whereas the share of outpatient preparations remained relatively stable, changing from 93.1% to 92.3%. Outpatient parenteral use showed a mostly steady decline (0.18 to 0.08). Inpatient parenteral consumption levels fluctuated through years (range: 0.04-0.14), yet remained almost unchanged in 2018 compared to 2010 (0.07 DID). Outpatient enteral DID peaked in 2014 (1.52), then lessened to lower than previous levels (0.87 in 2010 and 0.78 in 2018). Inpatient enteral consumption decreased to approximately one-seventh (0.007 to 0.001).

Conclusions: During the nine-year period, metamizole utilization decreased in Turkey mostly regardless of setting and route of administration. More prominent decline in use via parenteral route and outpatient setting might deserve designation of further studies that aim to explore the association of such trend to safety concerns.

4683 | Prescription opioids dispensed in Romania during 2017-2018

Irina Cazacu[1], Camelia Denisa Bucsa[2], Cristina Pop[1], Anamaria Cristina[1], Bogdan Apan[3] and Cristina Mogosan[1]

[1]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania; [3]University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania

Background: Opioids provide essential therapeutic options in bringing moderate-to-severe pain relief. Unfortunately, even if published data from different European countries show an increase in opioid use, data pertaining to it are currently very scarce in Romania.

Objectives: To characterize the consumption of prescription opioids (PO) in Romania.

Methods: We retrospectively analyzed data provided by IQVIA Romania, which included prescriptions dispensed from retail pharmacies, originating from all 41 Romanian counties and the municipality of Bucharest, during 2017-2018, for morphine (oral and injectable), fentanyl (cutaneous and sublingual), oxycodone (oral), dihydrocodeine (oral), pethidine (injectable), tramadol (oral, injectable and intrarectal), tramadol+paracetamol (oral).

Results: Total PO consumption, expressed in DDD/1000people/day, was 0.321 in 2017 and 0.359 in 2018. Tramadol+paracetamol (0.186 in 2017 and 0.223 in 2018, respectively) and tramadol (0.085, 0.086), followed by morphine (0.017, 0.015), fentanyl (0.012, 0.014) and dihydrocodeine (0.011, 0.010), were the most dispensed opioids. For both years, tramadol+paracetamol (72.8%) and tramadol (20.9%) had also the highest number of prescriptions, followed by fentanyl (2.7%), morphine (1.7%) and dihydrocodeine (0.9%). The two main indications for tramadol+paracetamol and *tramadol use* were polyarthrosis (7.0% and 8.3%, respectively) and dorsalgia (6.7%, 6.0%), followed by *intervertebral disc disease (6.0%) for* tramadol+paracetamol and gonarthrosis (4.9%) for tramadol. Morphine, fentanyl and dihydrocodeine were mostly prescribed for pain relief in case of lung cancer (13.1%, 11.1% and 13.4%, respectively), breast cancer (10.4%, 10.5%, 11.9%) and prostate cancer (6.9%, 7.1%, 8.7%). The highest regional opioid consumption, during 2017-2018, was in Bucharest (9.2%), followed by the counties Prahova (8%), Hunedoara (7.6%), Constanta (5.4%) and Mures (5.1%).

Conclusions: Tramadol in association with paracetamol or alone was the main PO dispensed in Romania during 2017-2018, and it was mainly indicated for pain management in case of rheumatic diseases. Regarding lung, breast or prostate cancer, morphine was the main opioid prescribed to provide analgesia. Continuous education on opioid use, to ensure safe and effective treatment of painful conditions, is a justified necessity at present in Romania.

4685 | Impact of changes in controlled drugs legislation on benzodiazepine and Z-drug prescribing in Ireland

Cathal A. Cadogan[1], Colin P. Bradley[2] and Kathleen Bennett[1]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]University College Cork, Cork, Ireland

Background: In May 2017, new controlled drugs legislation targeting benzodiazepines and Z-drugs was implemented in Ireland over concerns relating to diversion of valid prescriptions and drug misuse. The legislation introduced additional prescribing requirements and possession of these medications without a prescription is now a criminal offence.

Objectives: The objective was to examine the impact of the Misuse of Drugs Regulations 2017 on benzodiazepine and Z-drug prescribing in Ireland using national pharmacy claims data.

Methods: A repeated cross-sectional analysis was conducted using publically available monthly dispensing data from the General Medical Services (GMS) pharmacy claims database, the largest public health scheme, maintained by the Primary Care Reimbursement Services. The study population comprised all GMS-eligible individuals aged ≥16 years from January 2016 to September 2019. Monthly prevalence (%) was calculated as the number of patients in receipt of at least one of the medicines divided by the GMS eligible population and trends were examined over time. Segmented regression analyses were used to examine changes in the slope before and after introduction of the legislation stratified by gender and age groups. Odds ratios

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(OR) and 95% confidence intervals (CIs) for monthly change are presented.

Results: The prevalence of benzodiazepine and Z-drug prescriptions issued on the GMS in January 2016 was 8.3% and 6.0%, respectively. Prior to the legislation (January 2016 to April 2017), there was a significant monthly decline in benzodiazepine prescribing (OR 0.998; 95% CI 0.998, 0.999; p<0.001) but no significant change in Z-drug prescribing (OR 1.00; 95% CI 1.000, 1.000; p=0.66). Following introduction of the legislation (May 2017 to September 2019), the decline in benzodiazepine prescribing was not sustained (OR 1.001; 95% CI 1.001, 1.002; p<0.001) and a marginal increase was observed in Z-drug prescribing (OR 1.002; 95% CI 1.001, 1.002; p<0.001). However, there were differences in the youngest and oldest age groups, with significant increases in benzodiazepine and Z-drug prescriptions issued to the youngest subgroup (16-44 years) for both genders and significant decreases post-legislation in the oldest age group (≥65 years) for both genders.

Conclusions: This study indicates that the introduction of new legalisation had limited impact on benzodiazepine and Z-drug prescriptions issued on the main public health scheme in Ireland. Interventions targeting specific population subgroups may be needed if sustained reductions in prescribing are to be achieved.

4692 | Antidepressant use and concurrent psychopathology in Danish children, adolescents and young adults

Rikke Wesselhoeft[1], Peter B. Jensen[1], Lotte Rasmussen[1], Johan Reutfors[2], Lena Brandt[2], Kari Furu[3], Svetlana Skurtveit[4], Randi Selmer[3], Per Damkier[5], Anton Pottegård[1] and Mette Bliddal[6]
[1]University of Southern Denmark, Odense, Denmark; [2]Karolinska Institute, Stockholm, Sweden; [3]Norwegian Institute of Public Health, Oslo, Norway; [4]Norwegian Institute of Public Health, Oslo, Norway; [5]University of Southern Denmark, Odense, Denmark; [6]University of Southern Denmark, Odense, Denmark

Background: The use of antidepressants in children and young adults varies widely between the Scandinavian countries in spite of similar health care systems and medication guidelines.

Objectives: To describe antidepressant use among young Danes, providing information for future comparisons of utilization patterns between the Scandinavian countries.

Methods: Population-based study design including all Danish individuals aged 5-24 years, who filled an antidepressant prescription during 1997-2018. Incidence rates were determined by sex and age groups. Treatment duration was calculated from 2012-2018 using a Kaplan-Meier curve. Concurrent psychiatric disorders were defined as a diagnosis assigned at mental health clinics ± one year of filled antidepressant prescription.

Results: We identified 175,393 antidepressant users. The incident antidepressant use increased from 3 to 10 users/1,000 inhabitants from 1997-2010 and decreased to 6 users/1,000 inhabitants in 2018. New use of selective serotonin reuptake inhibitors (SSRI) was the main driver for the increase in antidepressant use, reaching a peak of 9/1,000 in 2010. Individuals aged 15-19 and 20-24 years constituted the largest user groups, with 9 and 12 female users/1,000, and 4 and 7 male users/1,000, respectively in 2018. Female/male ratios were 2.3 at age 15-19 years and 1.7 at age 20-24 years. Among 10-14-year-old users, 66% and 39% continuously filled antidepressant prescriptions after 12 and 24 months respectively, which was markedly higher than other age groups (42-50% and 21-25%, respectively). Within a two-year time window, 40% of new antidepressant users were assigned with a psychiatric disorder diagnosis. Non-internalizing disorders were the most common diagnoses (21%), followed by any anxiety disorder (20%) and depression (16%).

Conclusions: The incidence of antidepressant use peaked in 2010, and 15-24-year-old females were approximately twice as likely to start antidepressant treatment than males. Somewhat surprisingly, treatment duration was longest for 10-14-year-old individuals. Also, less than half of new users were assigned with a concurrent psychiatric disorder, whereof non-internalizing disorders were the most frequent group. These findings suggest that antidepressant use in young Danes is often initiated without licensed indications. This study will be followed by similar analyses of Swedish and Norwegian data by our group.

4694 | Spatial exploration of deprivation driven inequalities in opioids prescribing in English primary care: A cross sectional analysis

Magdalena Nowakowska, Salwa Zghebi, Rosa Parisi, Li-Chia Chen, Darren M Ashcroft and Evangelos Kontopantelis
University of Manchester, Manchester, United Kingdom

Background: Over 23 million opioid prescription items were dispensed in English primary care in 2018/19. The levels of prescribing are not distributed equally across regions and populations. A greater understanding of the geographical differences and social drivers of opioid prescribing is needed to guide policy responses and interventions.

Objectives: To explore regional variations in opioid prescribing in England and the role of socio-economic deprivation in driving inequalities in opioid prescribing.

Methods: Cross-sectional study using national primary care prescription data. The prescribing of opioids in each general practice was quantified by Defined Daily Doses (DDD) and attributed to 32,844 Lower Layer Super Output Areas (LSOA), geographical units representing approximately 1,500 people. Linear regression was used to model the effect of socio-economic deprivation, measured by the Index of Multiple Deprivation 2019 quantiles, on levels of prescribing. The model accounted for the proportion of females and people over 65 year old, rurality/urbanity of the area, and prevalence of cancer, palliative care, depression, severe mental illness (SMI), rheumatoid arthritis, and obesity. Within higher organisational areas (Clinical

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Commissioning Groups, CCG), adjusted DDD were estimated and compared at each deprivation level.

Results: In total, 5,350,151,699 DDD of opioids were prescribed. Prescribing of opioids, measured by DDD/1000 populations/day, was not distributed randomly between LSOA and varied between 4 and 1,905 DDD/1000 population/day. On average, 93.8 (SD: 1.9, $p < 0.001$) more DDD/1000 population/day were prescribed in the most deprived compared to the least deprived areas. Prevalence of cancer and SMI were negatively associated with opioid prescribing, and the remaining conditions had a positive association. Smaller LSOA and LSOA with a smaller proportion of females prescribed fewer opioids. A higher proportion of population over 65 was associated with higher prescribing. On average, opioid prescribing was 33.6 DDD/1000 populations/day (SD: 2.2, $p < 0.001$) higher in urban compared to rural areas. Within individual CCGs, the difference between prescribing in the least and most deprived areas varied by up to 200%.

Conclusions: Even after adjusting for differences in population structure, opioid prescribing practices differ significantly across the country, and geospatial deprivation is a key prescribing driver. Future policies and interventions should focus on high-prescribing low-geography areas and on tackling deprivation driven inequalities.

4719 | Trends of use of opioids in the period 2010 to 2018: Findings from a real-world cohort of 2 million patients in Spain

Isabel Hurtado, Gabriel Sanfelix-Gimeno, Salvador Peiro and Anibal Garcia-Sempere
FISABIO, Valencia, Spain

Background: the opioid epidemic has been well documented in the USA and Canada, but fewer data are available for Europe.

Objectives: to describe the trends of opioid use -volume of prescription, dosing and patients treated - in a European population with more than 4,2 million inhabitants 18 years and older.

Methods: we included all patients aged 18 and over who had at least one opioid prescription (including morphine, codeine, tramadol, buprenorphine, fentanyl, hydromorphone, oxycodone, petidine and tapentadol) in the region of Valencia, Spain, between 2010 and 2018. We described the trends of number of prescriptions, doses prescribed in Morphine Milligram Equivalents (MME) per inhabitant and volume of patients treated.

Results: more than 36 million treatments were prescribed in the whole period, and the number of treatments per year grew by twofold, from 2,597,727 prescriptions in 2010 to 5,115,498 in 2018. Tramadol use increased from 45.5 prescriptions/100h/year in 2010 to 76.2 in 2018 (84.2% of prescriptions in combination with paracetamol). Fentanyl figures rose from 4.7 to 17 prescriptions/100h/year; tapentadol was launched in 2011 and accounted for 8.5 prescriptions/100h/year in 2018. Total MME per inhabitant grew from 224.5 in 2010 to 644.9 in 2018, almost a threefold increase. Fentanyl MME/h more than tripled in the period (and accounted for 37% of the total MME/h in 2018), while morphine and tramadol increased by twofold. Oxycodone MME/h showed a tenfold increase and tapentadol showed the highest growth figures, overtaking tramadol at the end of the period. The number of patients receiving an opioid prescription every year more than doubled, with 336.193 having at least one prescription in 2010 versus 726.952 in 2018, for a total of 2.107.756 unique patients receiving at least one prescription in the period.

Conclusions: Opioid use increased by twofold from 2010 to 2018, as did the number of unique patients treated per year, while MME/h prescribed tripled in the period. Even if proportions seem still far from epidemic, urgent research is warranted on the appropriateness and health outcomes associated to these observed trends, especially for higher use and higher strength drugs.

4721 | Use of low-dose aspirin for primary prevention from 1998 to 2018: A nationwide danish cohort study

Espen Jimenez-Solem[1], Mikkel B Christensen[1], Erik L Grove[2], Morten Schmidt[3], Martin T Ernst[4] and Anton Pottegård[4]
[1]Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark; [2]Aarhus University Hospital, Aarhus, Denmark; [3]Aarhus University Hospital, Aarhus, Denmark; [4]University of Southern Denmark, Odense, Denmark

Background: Evidence suggests that low-dose aspirin for primary prevention of atherosclerotic cardiovascular disease (ASCVD) has an unfavorable benefit-risk balance.

Objectives: To assess the nationwide use of low-dose aspirin for primary prevention of ASCVD in Danish adults during the past two decades.

Methods: We identified all Danish adults redeeming low-dose aspirin prescriptions 1998-2018 and linked these data with hospital diagnoses of ASCVD. We estimated the incidence and prevalence over time of aspirin use for primary prevention defined as patients without a diagnosis of ASCVD. We also investigated age and co-medications adding to bleeding risk, including other platelet inhibitors, oral anticoagulants, and systemic glucocorticoids.

Results: We identified 1.1 million adults using aspirin during the 20-year study period. Low-dose aspirin was used by 4.1% (1998), 8.3% (2008), and 5.1% (2018) of the adult Danish population. Use for primary prevention was 3.1% (1998), 6.1% (2010), and 3.6% (2018), thus accounting for 70-77% of the total aspirin use. Aspirin use for primary prevention showed a strong age dependency, reaching more than 20% among those aged at least 80 years. Simultaneous use of at least one drug known to increase the risk of gastrointestinal bleeding events was fairly stable over the study period and amounted to 40% in 2018.

Conclusions: Low-dose aspirin use for primary prevention is common and increases with age reaching more than 20% among elderly >80 years. These data suggest a considerable potential for discontinuation of unnecessary aspirin treatment.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

4741 | Prescription patterns of denosumab in Spain: A population-based cohort study

Mar Martín-Pérez, Patricia García Poza, Belén Castillo Cano and Elisa Martín-Merino

Spanish Agency for Medicines and Medical Devices (AEMPS), Madrid, Spain

Background: Denosumab (Prolia®) is a human monoclonal antibody for osteoporosis in postmenopausal women and in men at increased risk of fractures. Long-term data on the prescription patterns of denosumab is scarce.

Objectives: To estimate the incident use of denosumab since 2011 and to describe the characteristics of new users.

Methods: A retrospective cohort study was performed in the Spanish Database for Pharmacoepidemiological Research in Primary Care (BIFAP). Patients ≥18 years, from 2011-2018 and ≥1 year of data, were followed until a first ever paper-based prescription or dispensation (for electronic prescriptions) for denosumab 60 mg/ml subcutaneous injection (Prolia®), death, loss to follow-up or end of study period. Incidence rates (IR) of denosumab prescriptions per 10,000 person-years (py) were computed overall, by age and sex and by calendar year. Characteristics of patients were ascertained any time prior or on the date of denosumab first prescription. Potential indications were explored among recorded diagnoses/treatments.

Results: Out of 8.4 million patients in the study population, 62,445 received a first prescription of denosumab. The resulting overall IR of denosumab prescription was 12.3/10,000 py, much higher in women (22.1/10,000 py) than in men (1.6/10,000 py) and peaked in women aged 70-79 years (69.9/10,000 py) and in men at 80-89 years (9.0/10,000py). IR increased from 0.3/10,000 py in 2011 to 16.5 in 2017 and decreased slightly thereafter until 15.4 in 2018. The majority of patients with denosumab prescriptions (93.7%) were women and the mean age was 71.3 (SD ± 10.7). Over 75% of patients had osteoporosis diagnosis recorded, 43.4% a history of fracture (nearly a third being vertebral fractures) and 6.7% osteopenia. Also, 41.8% of patients had glucocorticoids prescribed, 7.0% had breast cancer (of whom 50.3% had prescriptions of aromatase inhibitors) and 0.8% prostate cancer diagnosis (26% with recorded hormone therapy). Most patients (70.3%) had previously received therapy for osteoporosis (80% oral bisphosphonates), with 45.7% having used ≥2 different medications, and 90.4% had been prescribed calcium-vitamin D supplements.

Conclusions: Since its approval in 2011 the uptake of denosumab in Spain has been fast; in the first seven years the prescription rate increased steadily, but the rate observed in 2018 pointed to a negative trend that needs confirmation. As expected, use in women was much greater than in men and the main indication was osteoporosis. The majority of patients with denosumab prescriptions were not naïve to antiosteoporotic medications (mostly oral bisphosphonates).

4745 | Prescribing trend and factors associated with prescribing benzodiazepines in primary care in England: 2013-2019

Xinchun Gu, Laura Hayward, Teng-Chou Chen, Douglas Steinke and Li-Chia Chen

Centre for Pharmacoepidemiology and Drug Safety, Division of Pharmacy and Optometry, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom

Background: Benzodiazepines (BZDs) are commonly prescribed sedatives in primary care settings in England. The prescribing of BZDs ascribes to multiple factors such as deprivation and deprescribing policy. However, change in utilisation and factors influencing the prescribing of BZDs in general practices have not been fully studied.

Objectives: This study aimed to categorise the longitudinal trend of prescribing BZDs in England and investigate factors that may influence the prescribing of BZDs.

Methods: This cross-sectional study used monthly practice-level prescribing data and publicly available statistics in England between April 2013 and March 2019 from the United Kingdom National Health Service Digital and Office for National Statistics. The utilisation of prescribed BZDs was quantified as Defined Daily Dose (DDD)/1000 registrants. Descriptive statistics were used to report the annual utilisation of BZDs from 2013 to 2019. General practices were categorised by the trajectory model based on their quarterly utilisation of BZDs from April 2013 to March 2019. Mixed-effect multi-level regression was used to associate one-year utilisation of BZDs (April 2018 to March 2019) with contributing factors, i.e. demographic characteristics, the prevalence of diseases, lifestyle indicators and socio-economic status (Index of Multiple Deprivation [IMD] decile) by adjusting for the cluster-effect of Clinical Commission Groups.

Results: Overall, the annual utilisation of BZDs profoundly decreased from 2620 to 1810 DDD/1000 registrants between 2013 and 2019. Of the 5 decreasing trajectories categorised from the utilisation trends of 8050 general practices, quarterly utilisation of BZDs in the trajectory with the largest decrease (13% practices) dropped from 1327 to 856 DDD/1000 registrants from 2013 to 2019. The utilisation of BZDs in the most recent year was associated with the proportion of female or elderly, the prevalence of diseases and socioeconomic status in the practice. For every increase in IMD decile (less deprived), there was a significant decrease in the annual utilisation of BZDs of 26 DDD/1000 registrants.

Conclusions: Prescribed BZDs in primary care decreased from 2013 to 2019 in England, and there was variation in the longitudinal trajectory of prescribing BZDs. Multiple factors, including socioeconomic status, were associated with the prescribing of benzodiazepines. Further study will investigate the prescribing trends between BZDs and other medicines, such as opioids and the potential harms related to the concurrent prescribing.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4752 | Prescribing patterns of antidepressants in Slovenia: A nationwide database study

Nanca Cebron Lipovec, Andrej Anderlic and Igor Locatelli
University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia

Background: Antidepressants use is believed to be increasing, however the actual prevalence and incidence is not well known.
Objectives: To evaluate the prevalence and incidence of antidepressants use and antidepressants prescribing patterns between 2008 and 2018.
Methods: This retrospective cross-sectional study analyzed health claims data of all dispensed outpatient antidepressant prescriptions between 2008 and 2018. Data detailing the health claims of medications prescribed and dispensed to outpatients in Slovenia were obtained from a national database held by the Health Insurance Institute of Slovenia. Incidence was calculated based on the number of patients who received their first antidepressants prescription after at least 5 years without antidepressants treatment. Furthermore, we explored the course of treatment in this patient cohort and followed them until 2018.
Results: In 2018, a total of 147,000 patients (7.1% of inhabitants) received antidepressants prescriptions. The average patient age was 60 years and 69% were females. The prevalence was highest among the oldest patients (20% of inhabitants ≥80 years, 13% of inhabitants between 65 and 80 years). In the last decade, the prevalence increased most considerably among the oldest patients (25% increase) and was constant among patients below 50 years of age. The overall prevalence increased for 18%; however, applying the standardised age structure from 2008, the 10-year increase in antidepressants prescribing fell to 8%. The most frequently prescribed antidepressants belonged to selective serotonin reuptake inhibitors (SSRI, 60% share), namely sertraline and escitalopram. A steady increase in the share of duloxetine (11% in 2018, 5% in 2008) as well as mirtazapine (8% in 2018, 4.5% in 2008) has been observed. Similarly, increased shares have been observed for newer antidepressants (eg. agomelatin and vortioxetine), whereas older antidepressants are disappearing from the market. The incidence of antidepressant prescribing was approximately 26,000 patients (in 2013). Of these, almost half patients received up to two consecutive prescriptions and did not continue treatment. Amongst patients who received more than 2 consecutive prescriptions, approximately 40% patients discontinued treatment within the first 6 months.
Conclusions: The prevalence of patients receiving antidepressants is steadily increasing in the last decade, mainly due to the aging of the population. Two thirds of patients with newly prescribed antidepressants discontinue treatment within the first 6 months.

4763 | Trends in the use of systemic anti-inflammatory biologics in Denmark: A nationwide drug utilization study

Mette Reilev[1], Alexander Egeberg[2], Lene Dreyer[3], Jesper Hallas[1], Tine Jess[4] and Anton Pottegård[1]

[1]University of Southern Denmark, Odense C, Denmark; [2]Copenhagen University Hospital Gentofte, Gentofte, Denmark; [3]Aalborg University, Aalborg, Denmark; [4]Statens Serum Institut, Copenhagen, Denmark

Background: The introduction of biological therapy has had a profound effect on the treatment of inflammatory diseases. It is, however, expensive compared to traditional treatment. To promote appropriate, safe and effective use of these drugs, continued monitoring of utilization patterns is necessary.
Objectives: To provide an overview of utilization patterns of systemic anti-inflammatory biologics in Denmark.
Methods: Using nationwide Danish health registries, we investigated use patterns of systemic anti-inflammatory biologics during 2004-2018 among all Danish individuals and in cohorts of individuals treated for inflammatory bowel disease, inflammatory arthritis, or inflammatory skin disease separately. We described incidence rates, prevalence proportions as well as persistence to therapy.
Results: We included 37,961 Danish adults having 960,008 dispensing of a systemic anti-inflammatory biologic during 2004-2018. The study population were 42% male and the median age at receiving the first treatment series of a biologic was 45 years [IQR 31-58]. The assumed indication for receiving biologics were inflammatory arthritis (45% of the study population), followed by inflammatory bowel disease (28%), inflammatory skin diseases (8%), and other indications (19%). The rate of new users of any biologics increased from 0.4 per 10,000 person-years in 2004 to 8.4 per 10,000 person-years in 2018. Concurrently, the point prevalence proportion of any biologics increased markedly from 0.3 to 36 users per 10,000 persons in 2018. The trends in incident and prevalent use was mainly driven by an increasing use of TNF-alfa inhibitors and was evident across all disease entities. Within inflammatory arthritis, we observed the highest prevalent use of biologics with 13% of individuals with a hospital diagnosis of the disease receiving a biologic in 2018. This was followed by inflammatory bowel disease (8% in 2018) and inflammatory skin disease (5% in 2018). Within all disease entities, persistence to therapy was highest among users of TNF-alpha inhibitors, with 35%, 45%, and 47% of individuals with inflammatory bowel disease, inflammatory arthritis and inflammatory skin disease, respectively, being covered by therapy 2 years after initiation.
Conclusions: We document an extensive increase in the use of biologics, both overall and within specific disease entities. Underlying drug use patterns including a detailed evaluation of persistence and switching patterns, and predictors hereof should be investigated.

4765 | Inventory of biological and biosimilar medicine data sources in Europe at a national and hospital level: The EU-inbiobase initiative

Carla Sans[1,2,3], Lina Leguízamo[1,2,3], Judit Riera[1,2,3], Elena Ballarín[1,3], Mònica Sabaté[1,2,3], Alethea Charlton[4,5], Alessia Bonora[6], Xavier Vidal[1,2,3] and Luisa Ibanez[1,2,3]

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

[1]Clinical Pharmacology, Vall d'Hebron University Hospital, Barcelona, Spain; [2]Autonomous University of Barcelona, Barcelona, Spain; [3]Catalan Institute of Pharmacology Foundation, Barcelona, Spain; [4]Institute for Medical Information Processing, Biometry and Epidemiology - IBE, LMU Munich, Munich, Germany; [5]Pettenkofer School of Public Health, Munich, Germany; [6]Clinical Pharmacy, S.Orsola-Malpighi University Hospital, Bologna, Italy

Background: The heterogeneity of data sources for biologic/biosimilar medicines, together with a lack of standardization for recording data, contribute to challenges in undertaking cross-national biologic/biosimilar utilization studies.

Objectives: We aim to produce an inventory of databases (DB) containing biologic/biosimilar information at a national and hospital level in European university hospitals including the University Hospital Alliance (EUHA), thus facilitating further cross-national drug utilization studies.

Methods: The characteristics of national DB containing biologic/biosimilar medicines will be identified through literature review. Specific questionnaires will be sent to university hospitals in order to identify and describe such sources. Characteristics of both national and hospital DB, including administrative and clinical databases/registries will be collected: type of drug data, accessibility, anonymized patient data, medicine-related data, population coverage, and the possibility of linkage with other data sources. The internal and external DB validity will also be assessed.

Results: The questionnaire has been piloted in two third-level university hospitals (Spain, Italy). Its main limitations were the duration of completion and the difficulty finding information about the population coverage, validity and clinical/drug registries. These issues have been resolved and a new contact with the responders was set up to facilitate the search for the information in question. Moreover, information on national databases has been collected for the countries included in the EUHA (Austria, Belgium, France, Germany, Italy, Netherlands, Spain, Sweden, United Kingdom). The project proposal has been sent to the EUHA and the questionnaire will be presented at the EuroDURG 2020 Conference.

Conclusions: This inventory is a first step to ease the process of undertaking cross-national biologic/biosimilar utilization studies in Europe at national and hospital levels through developing a network of European hospitals to enhance research activities involving these medicines.

4782 | The role of high-deductible health plans on the use of lenalidomide

Shelley A. Jazowski[1], Lauren Wilson[2], Stacie B. Dusetzina[3], Yousuf Zafar[4] and Leah L. Zullig[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Duke University School of Medicine, Durham, NC; [3]Vanderbilt University School of Medicine, Nashville, TN;[4]Duke Cancer Institute, Durham, NC

Background: High-deductible health plans (HDHPs) have become one of the preferred forms of coverage in the United States. However, significant upfront out-of-pocket costs have been associated with patients forgoing or delaying orally-administered anticancer therapy. The role of HDHP enrollment on lenalidomide use in patients with multiple myeloma remains unknown.

Objectives: To compare the use of and costs associated with lenalidomide between patients with multiple myeloma who are enrolled in HDHPs or non-HDHPs.

Methods: We used MarketScan Commercial Claims and Encounters data from 2013 to 2017 to identify two cohorts: patients who were either enrolled in HDHPs or non-HDHPs in every month of the calendar year. Eligible patients were adults (aged 18 to 64) diagnosed with multiple myeloma (International Classification of Diseases, version 9 [ICD-9] code 203.00; ICD-10 code C90.0); and who had continuous prescription coverage for the full calendar year in which diagnosis occurred. We used descriptive statistics and Cochran-Armitage tests to examine trends in the annual use of and costs (adjusted to 2017 dollars) associated with lenalidomide, and log-binomial regression models to evaluate the association between HDHP enrollment and use of and $0 out-of-pocket costs for lenalidomide in a calendar year.

Results: Among patients enrolled in HDHPs, the rate of lenalidomide use increased from 26.4% in 2013 to 38.8% in 2017 (p<0.001). Similarly, lenalidomide use increased from 28.8% in 2013 to 36.4% in 2017 (p<0.001) among non-HDHP enrollees. There was no significant association between HDHP enrollment and lenalidomide use in a calendar year (RR: 1.06, 95% CI: 1.00-1.12). Mean lenalidomide costs significantly increased among both HDHP and non-HDHP enrollees, with average spending equaling $114,556 (SD: $55,099) and $107,315 (SD: $60,675) in 2017, respectively. Mean out-of-pocket costs for lenalidomide increased from 2013 ($280, SD: $923) to 2014 ($367, SD: $1,002), but remained consistent through 2017 among non-HDHP enrollees (p=0.013). Compared to patients covered by non-HDHPs, HDHP enrollees were 44% more likely to have $0 out-of-pocket costs for lenalidomide in a calendar year (RR: 1.44, 95% CI: 1.34-1.55).

Conclusions: Lenalidomide use and mean costs significantly increased among HDHP and non-HDHP enrollees. However, HDHP enrollees were more likely to have $0 out-of-pocket costs, which indicates that enrollees reached their deductible and out-of-pocket maximum before initiating or in early treatment with lenalidomide.

4800 | Trends in the prevalence of polypharmacy and potentially inappropriate medication among people with type 2 diabetes

Monika P. Oktora[1], Sofa D. Alfian[2,3], Catharina C. M. Schuiling-Veninga[2], Jens H. J. Bos[2], Katja Taxis[2], Eelko Hak[2] and Petra Denig[1]

[1]University of Groningen, University Medical Center Groningen (UMCG), Groningen, Netherlands; [2]University of Groningen, Groningen, Netherlands; [3]Universitas Padjajaran, Jatinangor, Indonesia

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Although increasing trends in the prevalence of polypharmacy are of concern, not all polypharmacy is considered inappropriate. People with type 2 diabetes (T2D) often need at least 5 medications to treat multiple risk factors and prevent complications, but they may also receive potentially inappropriate medication (PIM).

Objectives: We aimed to assess trends in polypharmacy among T2D patients, stratified by age groups. Furthermore, we assessed trends in PIMs among elderly T2D patients with polypharmacy.

Methods: We conducted a repeated cross-sectional study over 5 years (2012-2016) using the Dutch University Groningen prescription database IADB.nl, with a study population of T2D patients aged ≥45 years. Polypharmacy was defined as the dispensing of ≥5 chronic drugs, and age was stratified in groups of 45-54 years, 55-64 years, and ≥65 years. PIMs were determined by applying the Beers Criteria for patients ≥65 years with polypharmacy. There were 24 PIMs criteria that could be defined in IADB database, including 11 at therapeutic class level and 13 individual drug substances. A sumscore of the number of PIMs per patient was calculated and linear-by-linear chi-square tests were conducted to explore trends in PIMs

Results: The prevalence of polypharmacy increased from 41.3% in 2012 to 43.7% in 2016, with a peak of 44.3% in 2015. The absolute increase over the study period was 1.3% in the 45-54 years old, 2.3% in the 55-64 years old, and 2.1% in the ≥65 years old. The highest prevalence in 2016 was seen in oldest age group (52.0%), whereas this was 34.6% (55-64 years) and 23.3% (45-54 years) in the younger age groups. In this oldest age group with polypharmacy, preliminary results show the highest prevalence of PIMs for benzodiazepines (13%), antidepressants (8%), and dipyridamole (6%). The percentage of older patients with at least 1 PIM decreased from 29.6% in 2012 to 27.5% in 2016. The decreasing trend in the number of PIMs per patient was statistically significant.

Conclusions: Polypharmacy is common in T2D patients with a slight increase in the study period, particularly in patients of 55 years and older. In older patients this increase may not be inappropriate, since the number of PIMs per patient slightly decreased in this period.

4814 | Prescribing patterns in patients with type 2 diabetes in slovenia: A nationwide pharmacoepidemiological study

Spela Zerovnik, Mitja Kos and Igor Locatelli
University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia

Background: Metformin is recommended as a first-line therapy according to the national guidelines on type 2 diabetes management in Slovenia. Currently, it is not clear whether the initiation of antidiabetic therapy follows the guidelines and how it affects the management of diabetes.

Objectives: To explore prescribing patterns of antidiabetic medicines in patients with type 2 diabetes in Slovenia.

Methods: We performed a nationwide pharmacoepidemiological study using health claims data on prescription drugs from 2005 to 2018 obtained from the Health Insurance Institute of Slovenia. We evaluated the incidence of type 2 diabetes based on dispensed prescriptions for antidiabetic medicines. Incidence was calculated on the basis of patients, who received their first prescription for antidiabetic medicine over the period of 3 years, excluding patients under 45 years of age that received insulin as first-line therapy. Furthermore, we explored course of treatment in patients with type 2 diabetes who received first prescription for antidiabetic medicine in 2014. Patients were followed until the end of 2018. The risk for change in antidiabetic therapy (switch or add-on therapy) was evaluated using Cox regression model with age, sex, region and concomitant therapy as covariates.

Results: The incidence of type 2 diabetes was highest in 2009 (n=10,055) and lowest in 2018 (n=8,427). The majority of patients started treatment with metformin monotherapy; however, the percentage of those patients has increased over the years from 50% in 2008 to 66% in 2018. On the other hand, the percentage of patients who started treatment with sulphonylurea monotherapy has decreased over the years from 24% to 7%. The percentage of patients who started treatment with combination of metformin and sulphonylurea remained relatively constant over the years (around 14%). From a cohort of patients who initiated therapy with metformin or sulphonylurea in 2014, 27% discontinued and 31% changed their therapy during the follow-up period. When compared to metformin, sulphonylurea was associated with 29% higher risk for change in antidiabetic therapy [HR 1.29 (95% CI 1.21-1.49)]. Patients under 65 years of age were more likely to change their therapy [HR 1.31 (95% CI 1.16-1.48)] compared to patients aged 65 or more.

Conclusions: Initiation of diabetes treatment with metformin monotherapy is increasing, while initiation with sulphonylurea monotherapy is decreasing. Patients who initiated treatment with sulphonylurea were more likely to change their antidiabetic therapy compared to patients who initiated therapy with metformin.

4839 | Prescribing trends of antihypertensive drugs in the United Kingdom: A 30-year assessment

Julie Rouette[1,2], James M Brophy[1,3], Tibor Schuster[1] and Laurent Azoulay[1,2]
[1]McGill University, Montreal, QC, Canada; [2]Jewish General Hospital, Montreal, QC, Canada; [3]McGill University Health Centre Research Institute, Montreal, QC, Canada

Background: Antihypertensive drugs are among the oldest and most commonly prescribed drugs among adults. To date, however, few studies have described how these drugs are being prescribed in the natural setting of clinical practice.

Objectives: To describe the incidence and prevalence of antihypertensive drugs over a 30-year period in primary care practices in the United Kingdom (UK).

Methods: We used the UK Clinical Practice Research Datalink to identify all patients at least 18 years of age with ≥1 antihypertensive drug prescription between January 1, 1989 and December 31, 2018.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

These included thiazide diuretics, other diuretics, angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), calcium channel blockers (CCBs), beta blockers, and other drugs (vasodilators, centrally acting agents, ganglion blockers, and renin inhibitors). We calculated annual incidence rates (IRs) of patients with any new antihypertensive drug prescription over the total number of person-time at risk for each calendar year. We also calculated the annual prevalence of use for each antihypertensive drug class.

Results: A total of 2.7 million patients were issued 287 million antihypertensive drug prescriptions over the 30-year period. The mean age of patients newly treated with an antihypertensive drug was 55.7 years (standard deviation: 17.1) and female patients were more prevalent (54.4%). In 1989, most patients initiated their antihypertensive treatment with thiazide diuretics (IR: 20 per 100 person-years), with a slight decline by 2018 (IR: 17 per 100 person-years). In contrast, between 1989 and 2018, initiation rates for ACE inhibitors rose from 7 to 42 per 100 person-years and represented the majority of antihypertensive drugs initiated in 2018. Patients initiating ARBs also rose over time, from 0.1 per 100 person-years in 1995 (when ARBs became available) to 18 per 100 person-years in 2018. CCBs initiation rates increased from 19 per 100 person-years in 1989 to 40 per 100 person-years in 2018. Finally, the initiation of beta-blockers remained relatively stable during the 30-year period, with initiation rates of 32 per 100 person-years in 1989 to 38 per 100 person-years in 2018. In terms of prevalence of use, thiazide diuretics have seen the largest decrease of all antihypertensive drugs during the 30-year period, from a prevalence of 16% in 1989 to 9% in 2018.

Conclusions: While the initiation of thiazide diuretics slightly decreased in the last thirty years, its prevalence of use has seen the largest decrease among all antihypertensive drugs. This is likely due to the increased utilization of ACE inhibitors and CCBs.

4866 | Using the web 2.0 to inform on drug utilisation worldwide

Alessandra Spanu[1], Roman Keller[1], Milo Alan Puhan[1], Antoine Flahault[2], Christian Lovis[3], Margot Muetsch[1] and Raphaelle Beau-Lejdstrom[1]

[1]University of Zurich, Zurich, Switzerland; [2]Université de Genève, Genève, Switzerland; [3]Université de Genève, Genève, Switzerland

Background: Real-world drug utilization is often difficult to assess through traditional data sources (e.g. drug sales, prescription volumes or Electronic Health Records EHR). The appropriate use of the web 2.0 or online user-generated content could provide an easier and timely access to information on medication's utilization.

Objectives: We aim to assess characteristics of studies comparing drug utilization extracted from the WEB 2.0 to other sources.

Methods: We searched Medline, Embase, Web of Science and Scopus until November 25th, 2019. All studies assessing the utilization of any medications, vaccines, vitamins, prescription drugs and nicotine alternatives using Google trends/Insight, Facebook, Twitter and Instagram and comparing it to other data sources on drug utilization were included.

Results: Of 6,563 deduplicated publications retrieved, 16 matched our inclusion criteria. A total of nine studies found significant correlations in drug utilization between web data and comparative data for all drugs investigated, whereas two studies found correlations only for some of the drugs included. The remaining five studies used other analysis methods to evaluate the association between the two sources. Vaccines (n=5) and antibiotics (n=3) represented the two most frequently investigated drug categories. Social media and websites targeted to retrieve drug utilization data comprised Google Trends (n=10), Twitter (n=3) and other Google Search services (n=3).

Conclusions: Our results indicate the emerging potential of web data used as an alternative method to collect drug utilization data in nearly real-time without requiring expensive and time-consuming investigations.

4882 | Discontinuation and switching rates among women of childbearing age taking oral hormonal contraceptives: A retrospective cohort study in the United States

Sebastian Jugl[1,2], Amie Goodin[1,2], Carl Henriksen[1], Almut G Winterstein[1,2] and Joshua Brown[1,2]

[1]University of Florida, Gainesville, FL; [2]Center for Drug Evaluation and Safety (CoDES), Gainesville, FL

Background: Women may discontinue or switch contraceptive methods because they are dissatisfied with the method, are concerned about potential side effects, or experience side effects. The resultant gap from discontinuation accounts for an estimated 20% of unintended pregnancies.

Objectives: The objective of this study was to describe discontinuation and switching rates for oral contraceptive products in women of childbearing age in the U.S.

Methods: This retrospective cohort study utilized IBM MarketScan commercial claims data from 2005 to 2018. New users of oral contraceptives aged 15-44 were included and 12-months enrollment prior to new contraceptive use was required. Index date was the first oral contraceptive dispensing date, and specific progestin components were noted. Women were followed from index date until they switched from the index contraceptive, discontinued the index contraceptive, 12 months following initiation if maintained use of index contraceptive, end of enrolment, or end of the study period. Switching was defined as: use of a different route of administration, different dose of estrogen, or a different progestin component product. Discontinuation was defined as first 30-day gap in contraceptive use. The combined unadjusted switching and discontinuation rate were compared between progestin products.

Results: During this period, nearly 3.2 million women started an oral contraceptive and met our inclusion/exclusion criteria. The average follow-up time was about 6-months and contributed over 1.6 million

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

person-years of follow-up time. The overall switch/discontinuation (S/D) rate was 1.35 per person-year. Progestin only products, containing levonorgestrel (4.67 per person-year) and norethindrone (1.98) had the highest overall S/D rate as well as the combination product containing an older estrogen component, mestranol+norethindrone (2.22 per person-year). Other combination products of ethinyl estradiol with varying progestin ingredients had rates ranging from 1.14-1.42 and were not significantly different from each other. Discontinuations made up the majority (~80%) of observed events for all products.

Conclusions: Progestin only products and an older generation combination product had higher switching and discontinuation rates while rates of switching and discontinuation between newer generation combination products did not significantly differ. Future work will identify risk factors associated with switching and discontinuation, such as additional medication information and patient characteristics.

4912 | Comparing drug expenditures in the Scandinavian capitals

Martin Erik Nyeland[1], Love Linner[2], Kristine Olsen[3], Espen Jimenez-Solem[1], Gustaf Befrits[2] and Björn Wettermark[4]

[1]Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen, Denmark; [2]Region Stockholm, Stockholm, Sweden; [3]Norwegian Institute of Public Health, Oslo, Norway[4]Uppsala University, Uppsala, Sweden

Background: Pharmaceutical expenditure has been rising rapidly in most countries, partly attributed to the introduction of new expensive medicines. In recent years the drug market has changed with an increasing number of medicines introduced in the hospital setting. Cross national comparative studies on drug utilization are valuable tools to identify areas for improvement, few such studies have been conducted in the hospital setting.

Objectives: To compare drug expenditures between three Scandinavian capital regions in the hospital setting, to identify areas for improvement.

Methods: In this cross-sectional study, we compared the top substances (ATC4th and ATC5th level) by pharmaceutical expenditure 2017-2019 between the three Scandinavian capital regions of Copenhagen (1.8 million inhabitants), Oslo (0.7 million inhabitants) and Stockholm (2.4 million inhabitants). All analyses were based on sales data including all medicines used in hospitals and dispensed medicine in ambulatory care. Comparisons at 4th level ATC included refunds and rebates for all regions.

Results: In 2019, specialist medicines administered or prescribed in the hospital setting, dominated the top-15 medicines by expenditure in all three regions. However, there were differences in the rank and volume of most of these medicines. The specialist drugs accounting for the highest spending were aflibercept, coagulation factor VIII and adalimumab in Copenhagen, Oslo and Stockholm, respectively. Comparisons on the 4th ATC level revealed that Stockholm overall had higher relative net costs for TNF-inhibitors than the two other regions.

Conclusions: The drug market has changed with specialist medicines administered or prescribed in hospitals dominating expenditure in all the three Scandinavian capitals. However, there are substantial differences between regions in rank order and expenditure. Cross national comparative studies may therefore be used to identify areas for improvement.

4917 | Antidepressant use and adherence among breast cancer patients using tamoxifen

Sara Dejene, Jihye Park, Sophie E. Mayer, Alan Kinlaw, Hazel B. Nichols, Michele Jonsson-Funk, Virginia Pate, Eliza M. Park, Katherine E. Reeder-Hayes and Jennifer L. Lund

University of North Carolina Chapel Hill, Chapel Hill, NC

Background: Tamoxifen is a selective estrogen receptor modulator that is widely used for the treatment of early and advanced stage, ER- and PR-positive breast cancer. Antidepressants may also be prescribed to manage depressive or menopausal symptoms that arise after a breast cancer diagnosis or due to anti-neoplastic treatments, including tamoxifen. While results from existing literature are conflicting, some evidence suggests that certain antidepressants may inhibit CYP2D6, an enzyme involved in tamoxifen metabolic activation, thus reducing its effectiveness.

Objectives: To characterize use of antidepressants among tamoxifen users - particularly paroxetine, fluoxetine, and bupropion, which may inhibit metabolism of tamoxifen.

Methods: Using the IBM Watson Health MarketScan databases (2000-2018), we identified women ages 18-64 with ≥1 tamoxifen prescription fill followed by ≥1 fill of an antidepressant within the next 12 months. We further required ≥1 year of continuous enrollment before and after the first antidepressant fill date. We estimated the proportion of SSRI and CYP2D6-inhibitor use in this cohort. We estimated 1-year adherence to antidepressant medications by calculating proportion of days covered (PDC) by a prescription fill, where adherence was defined using a threshold of 80%. We examined prevalence of mental health diagnoses in the year prior to the index antidepressant fill.

Results: We identified a total of 13,240 antidepressant initiators with at least one tamoxifen fill in the prior year. Median age at antidepressant initiation was 51 years (IQR: 46-55). Overall, 25.6% had a diagnosis code for depressive, anxiety, or adjustment disorder in the year prior to antidepressant initiation. SSRIs were most common class used in this population, with 41.4% receiving ≥1 fill and 36.4% whose index antidepressant was an SSRI. The most common CYP2D6 inhibitor received was bupropion (7.3%), followed by paroxetine (5.7%) and fluoxetine (5.1%). In this population, 35.3% of patients had a 1-year PDC of ≥80% for their index antidepressant, with adherence fluctuating slightly over time (32.0% in 2001, 38.7% in 2012).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: In this large commercial claims analysis, a large proportion of tamoxifen users with an antidepressant prescription had ≥1 prescription fill for an SSRI, and 17% had ≥1 fill for a known strong or moderate CYP2D6 inhibitor. Approximately one-third of patients remained adherent to their antidepressant, but further work is needed to determine whether adherence to these medications is related to concomitant use of tamoxifen among users of certain antidepressants.

4936 | Off-label gabapentin utilization for psychiatric indications using the food and drug administration adverse event reporting system database from 1993-2019

Brianna Costales, Joshua D. Brown, Carl Henriksen and Amie J Goodin
University of Florida, Gainesville, FL

Background: Gabapentin was approved in 1993 and has two narrowly defined FDA-approved indications. However, off-label gabapentin utilization is rising for a variety of conditions, most prominently for pain and psychiatric disorders. There are case reports of suicidal behavior associated with off-label gabapentin use in psychiatric disorders, but comprehensive safety evidence is limited.
Objectives: This study aimed to quantify on- and off-label utilization of gabapentin, and to examine adverse drug events (ADEs) among off-label utilization for psychiatric indications.
Methods: Combined data from the Legacy Adverse Event Reporting System and FDA Adverse Event Reporting System (FAERS) were analyzed from 1993 to 2019 Q3. Generic and brand names (Neurontin, Horizant and Gralise) were used to extract cases in which gabapentin only (i.e. combination products excluded) was reported. Cases of on-label indications (postherpetic neuralgia and partial onset seizures) were aggregated in total using Medical Dictionary for Regulatory Activities (MedDRA) preferred terms. Cases of off-label indications were aggregated in total with MedDRA high level group terms, as were ADEs, with stratification by indication and ADE type.
Results: After de-duplication, there were 8,074,989 unique ADE cases for the study period, of which 21,874 cases identified gabapentin as the primary suspect drug. Of gabapentin-primary cases, 92.9% had an off-label indication, of which 6.8% (n=1,491) were for off-label treatment of a psychiatric disorder. The top three psychiatric indications were manic and bipolar mood disorders/disturbances (n=449), anxiety disorders/symptoms (n=299), and depressed mood disorders/disturbances (n=259). Across these psychiatric indications, the most frequent ADEs were suicidal and self-injurious behaviors (18.2%) followed by therapeutic and nontherapeutic responses (6.7%).
Conclusions: Most gabapentin-associated cases in FAERS were for off-label uses, and off-label treatment for psychiatric conditions accounted for more than 1 in 20 ADEs. Gabapentin use for the top three identified psychiatric indications are not supported by evidence; no clinical trials have demonstrated gabapentin's efficacy for bipolar disorder, anxiety disorders, or depressive disorders. The most frequent ADE of suicidal behaviors echoes concerns raised by case and media reports, which warrants further investigation into the association of off-label gabapentin use with suicidality outcomes in order to improve drug safety.

4980 | Identification of opioids use disorder related emergency department visits from recently collected data of the national hospital care survey, 2016

Adewumi Adegboye
US Food and Drug Administration, Silver Spring, MD

Background: Opioid use disorders (OUD), associated with both illegal and legal prescription drugs such as heroin, oxycodone, hydrocodone, and morphine, continue to be a significant problem in the United States (U.S.). Counting and studying ED visits provides a way to better understand the morbidity associated with the problem so that we can appropriately care for these patients and plan interventions. In 2018, it is estimated that 10.3 million people, aged 12 years or older, reported having misused opioids in the past year (2). Hospital ED treatment for OUD has increased. From 2005 to 2014, it is estimated that the national estimates of OUD ED visits increased by 99% (1). The National Hospital Care Survey (NHCS) provides the opportunity to study patients' episodes of care related to OUD in hospital settings. NHCS collects all ED visits from a sample of hospitals in the U.S. The data include information on diagnoses, services received, discharge status, and patient demographics. Additionally, NHCS collects patient identifiers, providing the opportunity to link patients' episodes of care across hospital settings and to additional data sources such as the National Death Index (NDI). Although, not nationally representative, NHCS yields large datasets that permit the in-depth study of OUD ED visits.
Objectives: To use the 2016 NHCS to examine OUD related ED visits and examine other diagnosis records on these OUD related visits.
Methods: Participating NHCS hospitals submit visit information from administrative claims (UB-04) or electronic health records (EHR). This study defines OUD as any-listed diagnosis of ICD-10-CM code F11.10 to F11.99. OUD ED encounters will be examined by age, sex, and associated characteristics (e.g., current smoking status, other substances involved in the visit, and mental health disorders).
Results: In 2016, 124 NHCS hospitals submitted ED data, comprising approximately 7 million ED encounters. Of these ED encounters, 21,422 (0.3%) were identified as relating to OUD. Approximately 47% of OUD encounters were patients between the ages of 16-34. Patients between the ages of 35-54 accounted for 38% of OUD encounters and 15% were patients aged 55 and over.
Conclusions: Although NHCS data are not nationally representative, they still contain a large volume of records, and can be used to demonstrate the analytic capacity to effectively identify OUD ED visits. In addition, these data contain patient identifiable information that provide the ability to identify multiple episodes of care for a unique patient and to link to other data sources such as the NDI.

4991 | Comparison of new oral anticoagulants use in atrial fibrillation patients from pivotal clinical trials vs southern Italian real-world setting

Ylenia Ingrasciotta[1], Andrea Fontana[2], Valentina Ientile[1], Maurizio Pastorello[3] and Gianluca Trifirò[1,4]

[1]*University of Messina, Messina, Italy;* [2]*Fondazione Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy;* [3]*Palermo Local Health Unit, Palermo, Italy;* [4]*A.O.U. Policlinico "G. Martino", Messina, Italy*

Background: Patients enrolled into pivotal randomized controlled trials (RCTs) may differ from real-world (RW) patients.

Objectives: To explore the generalizability of findings from NOACs pivotal RCTs to a RW setting with atrial fibrillation (AF) from Southern Italy.

Methods: Fully anonymized data were extracted from the claims database of Palermo Local Health Unit from 2013 to 2017. In line with RCTs, incident NOAC users (washout >1 year) with AF were grouped based on the dispensed NOAC (low/high dose dabigatran/edoxaban, any dose of apixaban/rivaroxaban). The baseline characteristics of enrolled patients in NOAC pivotal RCTs were identified from the original publications and compared with those of RW setting. Individual-level RW setting data were propensity score matched 1:1 on simulated RCT patients' data by age, sex and CHADS2 score. RCT pseudo-data were generated and matched 1,000 times on the basis of RCTs descriptive statistics. At each iteration, both effectiveness (e.g. stroke/myocardial infarction) and safety (e.g. major bleeding, including gastrointestinal (GI)/intracranial bleeding (ICH)) outcomes were assessed within the matched population setting (edoxaban users excluded).

Results: Overall, 42,336 NOAC users with AF were enrolled in the pivotal RCTs in 2005-2013 vs. 7,092 incident NOACs users with AF from the RW setting in 2013-2017. In RW setting, female-male ratio was in favor of females (1.1) and patients were older (mean age: 76.0 ±8.6 yrs) than RCT population (70.7±9.2 yrs); 34.2% of these were >80 years old. After the matching, 545 (68.6%), 458 (72.1%), 1,432 (47.3%) and 1,005 (47.6%) incident NOAC RW users of low- and high-dose dabigatran, rivaroxaban and apixaban, respectively, had overlapping characteristics with pivotal RCTs population. During the follow-up, rate of ischemic stroke (IS) events was lower in high-dose dabigatran users than in low-dose dabigatran users, both from RCTs/matched RW setting. In particular, compared to RCT population, rate of IS events was lower in RW users of high-dose dabigatran (0.1 vs. 0.9 per 100 PYs; P-value=0.010). As found in RCTs, rate of GI bleeding events was higher than rate of ICH events in RW setting. However, rates of GI bleeding events were lower in RW setting than those observed in RCT setting (P-value<0.001).

Conclusions: Characteristics of AF patients treated with NOAC in RW setting are substantially different from patients enrolled in pivotal trials (e.g. much higher proportion of very old patients and females). Heterogeneity of effectiveness and safety outcomes in the RW population was observed.

4997 | Ambulatory treatment of type 2 diabetes in the United States, 2013-2019

James Heyward[1], Sudipa Sarkar[2], Jacob Christopher[1], Rita Kalyani[2] and Caleb Alexander[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Johns Hopkins School of Medicine, Baltimore, MD*

Background: Type 2 diabetes afflicts more than 30 million U.S. adults and causes significant morbidity and mortality. The landscape of non-insulin antihyperglycemic therapy in the U.S. has transformed in recent years, but changes in prescribing patterns have not been studied.

Objectives: To examine trends in the pattern of non-insulin drug treatment of type 2 diabetes, including first- and second-line therapy, from 2013 to 2019.

Methods: We conducted a descriptive analysis of cross-sectional data using the IQVIA National Disease and Therapeutic Index (NDTI), a nationally representative audit of ambulatory physician practices in the U.S. We focused on visits for type 2 diabetes among patients age 35 and older in which one or more drugs were prescribed ("treatment visits"). We assessed both first- and second-line prescribing of non-insulin antihyperglycemic therapy for type 2 diabetes between September 2013 - March 2019.

Results: Ambulatory diabetes visits decreased from 33.5 million (M) treatment visits in 2014 to 31.8M treatment visits in 2018. Overall, metformin treatment visits declined from a total of 17.5M in 2014 to 16.1M in 2018; dipeptidyl peptidase 4 inhibitor (DPP-4i) visits declined from 6.0M to 5.1M; and sulfonylureas declined from 5.1M to 3.9M. During the same time period, use of sodium-glucose cotransporter-2 inhibitors (SGLT-2i) increased from 1.5M to 3.9M treatment visits and use of glucagon-like peptide-1 receptor agonists (GLP1-RA) increased from 1.2M to 1.8M. Among treatment visits where a single drug was prescribed, use of metformin declined from 70.0% of monotherapy in 2013 to 61.3% of monotherapy in 2019, while during the same period the share of monotherapy by GLP-1-RA increased from 2.9% to 10.4% and the share by SGLT-2i increased from 3.1% to 10.2%. Among treatment visits where metformin plus another drug was prescribed, the share of second line therapy accounted for by DPP-4i decreased from 40.5% of treatment visits in 2013 to 36.6% of treatment visits in 2019; sulfonylurea use declined from 38.8% to 21.4%; and use of SGLT-2i increased from 2.9% to 28.7%, while use of GLP1-RA increased from 6.5% to 9.2%.

Conclusions: During the past seven years, significant changes in the landscape of ambulatory care for type 2 diabetes have taken place, including modest declines in metformin monotherapy, moderate declines in second-line sulfonylurea use, and large increases in GLP1-RA and SGLT-2i use. These changes underscore the dynamic nature of drug utilization for diabetes in the U.S., and reflect life-cycle drivers including emerging evidence, evolving clinical guidelines and regulatory and payment policies.

5000 | Trends in gabapentin utilization in the United States, 2004-2016

Abisola Olopoenia, Sean Fleming and Linda Simoni-Wastila
University of Maryland, Baltimore, MD

Background: Off label use of gabapentin within the United States is currently estimated to range from 83 to 95%. Little is known about the trends in gabapentin utilization, especially among those with pain and mental health conditions.

Objectives: Our goal was to characterize the utilization of gabapentin among US adults overall, and among specific demographic (age, insurance) and clinical (chronic pain [CP], non-chronic pain [NCP], mental health disorder [MHD], neuropathic pain and opioid/benzodiazepine users) subgroups.

Methods: We conducted a retrospective longitudinal analysis using 2004-2016 Medical Expenditure Panel Survey (MEPS) data. We included all adults aged 18 and older. Clinical conditions were defined based on a diagnosis of CP (back, neck, joint, head or chronic pain), MHD (anxiety, depression, substance use disorders, personality disorders, mood disorders, adjustment disorders, and attention deficit hyperactive disorders), NCP (sprains, strains, fractures, and other connective tissue disorders) and neuropathic pain. Opioid/benzodiazepine utilization was defined as ≥1 prescription for either medication in each calendar year. We compared the annual prevalence of gabapentin utilization overall, and among demographic and clinical subgroups. Logistic regression was used to test trends over time.

Results: The study included 305,130 adults between 2004 and 2016. The annual prevalence of gabapentin users increased over the study period. The percentage of individuals who utilized gabapentin increased from 0.02% (95%CI, 0.02-0.03) in 2004 to 0.26% (95%CI, 0.24-0.28) in 2016 (p <.0001), an increase of 915.4%. All subgroups experienced increased gabapentin utilization; however, the increase in gabapentin utilization was highest among adults ≥65 (0.05% to 0.59%), publicly-insured individuals (0.04% to 0.43%), and those with CP (0.30% to 0.71%), MHD (0.04% to 0.69%), NCP (0.03% to 0.68%) and opioid/benzodiazepine users (0.08% to 0.78%.) When compared to 2004, gabapentin users in 2016 were significantly more likely to be female, publicly-insured, and diagnosed with CP, NCP, and/or MHD (p<.0001).

Conclusions: Gabapentin utilization has increased significantly over the years, especially among individuals with pain and mental health conditions. Given emerging evidence concerning gabapentin's association with respiratory depression and overdose, it is essential we comprehensively examine its ongoing utilization, especially among those who may be potentially more vulnerable to these adverse effects

5007 | Investigation of opioid analgesic use in primary care

Ömer Ataç[1], Volkan Aydın[2] and Ahmet Akıcı[2]
[1]*Department of Public Health, School of Medicine, Istanbul Medipol University, Istanbul, Turkey*; [2]*Department of Medical Pharmacology, School of Medicine, Marmara University, Istanbul, Turkey*

Background: Opioid use has been consistently reported to increase in various countries. It could be a matter of concern when it involves potent opioids due to their potential harm for the community.

Objectives: We aimed to describe utilization of opioid analgesics in the prescriptions of primary care physicians.

Methods: We analyzed all opioid-containing prescriptions of family physicians selected by systematic sampling in Istanbul in 2016. The prescriptions were included only if they contained single diagnosis to assess appropriateness of the particular indication. Drug groups were further compared by age group and gender.

Results: We identified 7,063 opioid prescriptions, where women constituted 60.9% of patients and the mean age was 49.3 ± 17.2 years. Around one in five (20.1%) of the patients who received opioid was ≥65 years old. The most common indication (12.5%) for an opioid prescription was "M79-other soft tissue disorders", followed by "R52-unclassified pain" (9.3%) and "M54-dorsalgia" (7.3%). Hypertension and gastroesophageal reflux disease (GERD) were identified among the top ten frequent conditions for opioid prescriptions (4.0% and 2.5%, respectively). Opioids were detected to constitute 39.1% (n=7,244) of all 18,540 drugs in opioid prescriptions. At ATC-4 level, "natural opium alkaloids" were the most commonly prescribed medications (81.8%), followed by "other opioids" (14.8%) and "phenylpiperidine derivatives" (3.4%). The vast majority of the prescribed opioids was codeine combinations (80.8%), followed by tramadol (9.9%) and tramadol + paracetamol combination (4.9%). In 18-64-years' age group, women were more likely to receive natural opium alkaloids (86.0%) compared to men (82.9%, p=0.006). On the other hand, men were more likely to be prescribed tramadol than were their female counterparts (56.3% vs 47.0%, respectively; p=0.004).

Conclusions: Primary care physicians seem to prefer weak opioids with a slight tendency of increased tramadol use in young-middle aged male patients. Though mostly used for acute painful conditions as expected, presence of hypertension and GERD among the top indications in encounters implies irrational opioid prescribing behaviors of the primary care physicians.

5020 | Prevalence and trend of opioid use after total knee arthroplasty in electronic health records

Zhenna Huang[1], Deepak Krishnan[2], Chantal Holy[1], Julia Hwang[1] and John Wright[1]
[1]*Johnson and Johnson, New Brunswick, NJ*; [2]*Mu-sigma, Bangalore, India*

Background: The use of opioids in United States has had a significant impact on both patients and society. Americans consume 80% of the global opioid while only having 5% of the world's population. Opioids are commonly used to treat chronic pain due to osteoarthrosis.

Objectives: This study aims to describe the prevalence of opioid use prior to primary total knee arthroplasty (TKA) and estimate the opioids use trend following TKA.

Methods: The Pan-Therapeutic electronic health records (Panther EHR) from the Optum database (2007-2019) were used to identify

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

TKA patients. The EHR data were available for a geographically diverse population of 80 million patients from more than 700 hospitals and 7,000 clinics. Preoperative and postoperative opioid use was measured by the number of opioid administration orders. Patients needed to have at least three-months baseline and one-year follow-up to be eligibly included. A multivariable logistic regression was developed to investigate the factors associated with opiate use 1-year post surgery.

Results: A total of 207,065 primary TKA were included in this study. Approximately 88.7% of the population had opioid administration three months prior to surgery. The mean number (± standard deviation) of opioid administration orders per patient had increased from 4.5±4.3 (median: 4) in 2007 to 8.8±4.8 (median: 9) in 2018. The percentage of patients who had opioids prior to surgery was 70% in 2007, 84% in 2012 and 93% in 2018. Around 10% of the cohort had opioid administration three months to six months after surgery (8% in 2007, mean: 0.58±3.01 orders, 10% in 2018, mean: 0.73±3.06 orders). Around 9% of the cohort had opioid administration nine months to twelve months after surgery (6% in 2007, mean: 0.44 ±3.35, 11% in 2018, mean: 0.73±2.80). Patients with higher functional comorbidity score, being current smoker and enrollment in Medicaid and Medicare insurance were associated with higher odds of consuming opiate nine months to twelve months after surgery.

Conclusions: Approximately 88% of TKA patients use opioids within the 3 months prior to surgery and this percentage has increased 23% during the study period. From 2007 to 2018, the mean number of opioid administration orders per patient has increased from 4.5 to 8.8 orders three months prior to surgery and 0.44 to 0.73 orders nine months to twelve months after surgery.

5021 | Trends and patient characteristics in concurrent use of opioids with high-risk medications among Arizona medicaid beneficiaries, 2011-2017

Ching-Yuan Chang[1], Juan M Hincapie-Castillo[1,2], Debbie L Wilson[1] and Jenny Lo-Ciganic[1,2]

[1]University of Florida, College of Pharmacy, Gainesville, FL; [2]University of Florida, College of Pharmacy, Gainesville, FL

Background: Concurrent use of opioids with benzodiazepines (BZDs), muscle relaxants, or gabapentinoids (GABs) is associated with an increased risk of opioid overdose. In response to the US opioid epidemic, states have enacted several policies to reduce high-risk opioid prescribing in the past few years. Little is known about recent trends and patient characteristics for concurrent use of opioids with high-risk medications.

Objectives: To examine the trends and patient characteristics of concurrent use of opioids with other high-risk medications in Arizona Medicaid from 2011 to 2017.

Methods: A cross-sectional study included Arizona Medicaid beneficiaries aged 18-64 with ≥1 opioid prescription. We included patients with opioid overdose, opioid use disorder, other substance use disorders, mental health disorders, musculoskeletal pain, HIV/AIDS, or hepatitis-C virus infection diagnoses. We examined patient characteristics and annual prevalence of concurrent use (defined as ≥30 overlapping days) of opioids with BZDs, muscle relaxants, and GABs. Cochran-Armitage tests were used to evaluate trend changes of concurrent use over time. A multivariable logistic regression model was used to identify the patient characteristics associated with the likelihood of concurrent use.

Results: Among 155,382 eligible beneficiaries in 2017 (mean age=40.1±12.7, 64.6% female), 19.0% had concurrent use of an opioid with any high-risk medication. The prevalence of concurrent use increased from 2011 to 2013, and then decreased by 2017 as follows: BZDs 11.6% to 22.7% and to 6.5%; muscle relaxants 11.9% to 26.7% and to 11.0%; GABs 8.0% to 14.7% and to 10.9 % (all P_{trend}<0.0001). Asians (OR=0.43, 95% CI=0.36-0.51), African Americans (OR=0.86, 95 %CI=0.82-0.90), Hispanics (OR=0.84, 95% CI=0.78-0.91), and Native Americans (OR=0.43, 95% CI=0.40-0.46) were associated with decreased odds of concurrent use of opioid with any high-risk medications compared to white beneficiaries. Characteristics significantly associated with concurrent use were married status (OR=1.62, 95% CI=1.56-1.75), being a native English speaker (OR=2.50, 95% CI=2.32-2.69), and higher Elixhauser comorbidity index (OR=1.21, 95% CI=1.20-1.21).

Conclusions: Concurrent use of opioids with other high-risk medications among Arizona Medicaid beneficiaries decreased from 2011 to 2017. However, at the end of the study period, one in five beneficiaries had concurrent use of opioids and other high-risk medications. Our findings suggest efforts to reduce high-risk opioid prescribing continue to be needed.

5023 | Melatonin use among children, adolescents and young adults: A Scandinavian drug utilization study

Rikke Wesselhoeft[1], Peter B. Jensen[1], Poul Jennum[2], Svetlana Skurtveit[3], Randi Selmer[3], Ingeborg Hartz[3], Lotte Rasmussen[1], Johan Reutfors[4], Lena Brandt[4], Lene A. Mølstrøm[5], Mette Bliddal[1] and Anton Pottegård[1]

[1]University of Southern Denmark, Odense C., Denmark; [2]University of Copenhagen, Copenhagen, Denmark; [3]Norwegian Institute of Public Health, Oslo, Norway; [4]Karolinska Institute, Stockholm, Sweden; [5]Mental Health Services in the Region of Southern Denmark, Odense C., Denmark

Background: The use of melatonin in children, adolescents and young adults is increasingly common, although there has been no licensed indication for Scandinavian children and adolescents until this year.

Objectives: We aimed to describe and compare the use of melatonin in the young Scandinavian population from 2012 to 2018.

Methods: Aggregate-level data on melatonin use (ATC code N05CH01) in Denmark, Norway and Sweden was extracted from publicly available data sources. Analyses considered annual prevalence and total use and were performed overall (age 5-24 years) and specified by age category (in 5-year intervals), sex and country. Information

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

about defined daily doses (DDDs) were only available for Denmark and Norway.

Results: The prevalence rates of melatonin use increased in the total Scandinavian population from 2012 (7 users/1,000 inhabitants) to 2018 (20 users/1,000 inhabitants) with no marked sex differences (females: from 6 to 20 users/1,000, and males: from 8 to 21 users/1,000, respectively). Sweden had an almost fourfold increase in prevalence rates (from 7 to 25 users/1,000), whereas prevalence rates doubled in both Denmark (from 6 to 12 users/1,000) and Norway (from 10 to 20 users/1,000). The increase in prevalent melatonin use from 2012 to 2018 was most pronounced for Scandinavian 15-19 year-olds (11 to 32 users/1,000) followed by 10-14-year-olds (9 to 23 users/1,000). Throughout the study period, the total annual amount of DDDs filled by children, adolescents and young adults in Norway and Denmark doubled (from 6.3 mill DDD in 2012 to 12.9 mill DDD in 2018). The intensity of melatonin treatment was higher in Norway compared to Denmark, with 2,860 and 5,520 DDDs/1,000 Norwegians in 2012 and 2018, respectively, compared to 1,936 and 4,114 DDDs/1,000 Danes in 2012 and 2018, respectively. Treatment intensity was highest for 10-14-year-olds in both countries with 8,062 DDDs/1,000 Norwegians and 6,135 DDDs/1,000 Danes in 2018, followed by 15-19-year-olds with 6,933 DDDs/1,000 Norwegians and 5,642 DDDs/1,000 Danes.

Conclusions: The number of young Scandinavian melatonin users (particularly 10-19-year-olds) increased rapidly in the last decade. Furthermore, overall treatment intensity increased and this finding was most pronounced for 10-14-year-olds. The utilization trends are concerning given the lack of licensed indications for melatonin use in children and adolescents and the limited knowledge of its long-term consequences.

5025 | A time series analysis of opioid use in Australian nursing homes from 2014 to 2019

Lisa G. Pont[1], Dung Chun (Lydia) Ko[1] and Gerard Stevens[2]
[1]*University of Technology Sydney, Sydney, Australia;* [2]*Webstercare, Sydney, Australia*

Background: Opioid use among older adults has more than doubled over the past decade globally. Nursing home residents are high medications users and at high risk of medication related harm, yet little is known about the trends in opioid use among nursing home populations.

Objectives: To explore trends in opioid use among Australian nursing home residents from 2014-2019.

Methods: A time series analysis using pharmacy individual resident supply data for residents of 35 Australian nursing homes between April 2014 and March 2019 was conducted. The data source included all medications, both prescribed and over the counter, for all residents of the 35 nursing homes. The rate of opioid use per 100 residents was calculated quarterly for use of any opioid, as well as for individual generic agents. A generalized additive model with polynomial smoothing was fitted to the data. Polynomials of increasing order were fitted, until the model fit (R^2) was maximised. The rate of change, averaged across the entire time period, was determined using linear regression.

Results: The study cohort included 4759 nursing home residents throughout the 5-year period. The average resident age was 81.2 years and 61% of residents in the cohort were female. Opioid use increased by 2.77 residents per 100 residents throughout the study period, increasing from 29.6% of residents in 2014, to 73.9% in 2019. The increasing use was driven primarily by increasing use of oxycodone and morphine.

Conclusions: Opioid use among nursing home residents increased considerably between 2014 and 2019 and appears primarily driven by increasing use of oxycodone and morphine. Future research to determine the appropriateness and harms associated with increasing opioid use in the vulnerable nursing home population is needed.

5036 | The utilization trends of analgesics and proton pump inhibitors in Turkey

Volkan Aydin, Caner Vizdiklar and Ahmet Akici
Marmara University School of Medicine, Istanbul, Turkey

Background: Widespread use of proton pump inhibitors (PPIs) and analgesics, particularly non-steroidal anti-inflammatory drugs (NSAIDs), raises debates about their potential excessive or irrational prescribing.

Objectives: This study aimed to examine utilization trends of analgesics and PPIs in Turkey.

Methods: We obtained nationwide consumption data of analgesics (NSAIDs, opioids, and others) and PPIs between years of 2014-2017 from IQVIA. Drug utilization was measured by DDD (defined daily dose)/1000 inhabitants/day (DID) unit.

Results: During the study period, analgesic utilization increased from 65.7 to 69.7 DID. Most of the consumption was through enteral route (96.2-96.4%) and in outpatient setting (97.9-98.1%). NSAIDs constituted 82.7-84.9% of all analgesic utilization while opioids ranged 1.4-1.7%, and the rest 13.5-15.9%. Consumption of NSAIDs (mean: 57.9 DID), increased by 7.4% (from 54.3 DID in 2014 to 58.4 DID in 2017), compared to a 0.2% reduction in all other analgesics. PPI utilization was found to regularly raise from 51.7 DID in 2014 to 69.9 DID in 2017. Only 0.8-0.9% of the PPIs were used parenterally and 1.3-1.5% in hospital setting. The most frequently consumed PPIs were lansoprazol (32.2%), pantoprazol (29.5%), and esomeprazol (25.7%) in 2014 compared to the reversing of the rank as esomeprazol (30.2%), pantoprazol (28.7%), and lansoprazol (28.3%) in 2017.

Conclusions: Utilization of examined drugs in Turkey exhibit an increasing trend for NSAIDs and a much higher (35%) increment for PPIs. Existing controversies about PPI overutilization occasionally signals excessive NSAID-PPI co-prescription in non-indicated conditions. Our findings might be explained by potential triggering effect of overuse of these drug groups on use of the other.

5041 | Rural variation of the impact of medicaid expansion on naloxone access

Yue Cheng[1], Patricia Freeman[1], Minji Sohn[2], Eugene Shin[1] and Chris Delcher[1]

[1]*University of Kentucky, Lexington, KY;* [2]*Ferris State University, Big Rapids, MI*

Background: The opioid epidemic is a major public health concern in the United States. Naloxone is a life-saving medication to prevent fatal opioid overdoses.

Objectives: This study evaluated the trends in access to naloxone by rural locations over the time as well as pre- and post- Medicaid expansion.

Methods: Naloxone dispensed, payer types, and the mean naloxone prescribing rate per 100,000 population in Medicaid expansion (32 states) and non-expansion states (19 states) over the study period by rurality were evaluated. 3-digit zip codes were classified into rural and non-rural areas. For rural areas, the percentage of the rural population was further stratified into quartiles. Cross-sectional analyses were conducted to describe the trend in naloxone dispensed pre- and post- Medicaid expansion in non-rural vs. rural areas.

Results: Naloxone dispensed in rural and non-rural areas increased notably (from 4.13 to 250.79 and from 4.90 to 468.42 in rural and non-rural areas respectively). The number of naloxone paid by cash decreased over 60% in both rural and non-rural areas, whereas other payers' share increased over time (paid by Medicaid increased by 16.74% and 29.49% in rural and non-rural areas, respectively). As rurality increased, the naloxone dispensing rate increased. The mean differences of naloxone dispensing rates ranged from 0.14 to 0.57 more in rural areas compared to non-rural areas and ranged from 0.69 to 1.79 more in more rural quartile compared to less rural quartile. Visual inspection suggested an immediate effect of Medicaid expansion in rural and non-rural areas. However, higher dispensing rates were sustained in rural areas whereas the rates converged in non-rural areas. The average rate of naloxone dispensed per 100,000 after Medicaid expansion increased more significantly in rural areas compare to non-rural areas.

Conclusions: Rates of naloxone dispensing increased over the study period with higher rates of naloxone dispensing in rural areas. Medicaid expansion may have increased naloxone access, especially in rural areas.

5056 | Methylphenidate adherence and loss to follow-up in ADHD children in a tertiary care psychiatric hospital

Nichaphat Kunacharoensuk[1], Tiwarat Kamjak[1], Nootjaree Kamduang[2] and Penkarn Kanjanarat[1]

[1]*Chiang Mai University, Chiang Mai, Thailand;* [2]*Rajanagarindra Institute of Child Development, Chiang Mai, Thailand*

Background: Methylphenidate is a common and effective medication treatment for ADHD in children. Little is known about long-term methylphenidate adherence and loss to follow up in this population.

Objectives: To determine the rates of methylphenidate adherence and loss-to-follow-up 3 years after the initiation of the treatment and factors associated with methylphenidate adherence.

Methods: We conducted a cross-sectional descriptive study using patient chart review. Children 6-12 years diagnosed with ADHD receiving methylphenidate treatment at a tertiary care psychiatric hospital in Thailand during January 2008-July 2012 were included. Methylphenidate was grouped by immediate-release or extended-release formulation. Adherence, using medication possession ratio (MPR), was measured using 80% cut-off in year 1 to 3. We collected data and tested whether age, gender, IQ, type of health insurance, distance from hospital, and care giver's relationship with the child, marital status, and education were associated with methylphenidate adherence using a binomial logistic regression model. Loss to follow-up of methylphenidate treatment was measured if no hospital visit over 6 months in one year was present.

Results: The study samples (n= 197) was male (84.3%) and diagnosed with ADHD at the age of 6-7 years (57.9%). Most patients were prescribed immediate-release methylphenidate (88.8%). First, second, and third year methylphenidate adherence rates (MPR≥80%) decreased over time (66.5%, 48.7%, and 45.2%, respectively). ADHD patients with care giver with higher education were more likely to adhere to methylphenidate than patients with care giver with less education (4.44, 95% CI, 1.02-19.34). Cumulative loss to follow-up rates were 21.8%, 24.4%, and 37.6% in 3 years.

Conclusions: Methylphenidate adherence in children was suboptimal and declined over 3 years after receiving the treatment. Care giver's education was associated with methylphenidate adherence in the first year of the treatment.

5087 | Opioid agonist therapy as treatment for opioid use disorder: Comparing duration, risks and frequency of healthcare encounters

Nima Tourchian and Mina Tadrous

University of Toronto, Toronto, ON, Canada

Background: Methadone and buprenorphine/naloxone (BUP) are considered first-line treatment options for opioid use disorder (OUD).

Objectives: The objective of this study is to compare duration of treatment, risks of overdose, and the frequency of interactions with healthcare professionals among people newly starting treatment with one of these medications.

Methods: We conducted a population-based propensity-score matched cohort study in Ontario among people newly initiating methadone or BUP between October 1, 2016 and September 30, 2017 using the Ontario Narcotics Monitoring System (NMS) database. The outcome was measured at 1-year follow-up, with reference to the cohort entry date. We excluded individuals under the age of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

18, individuals who had a methadone or BUP prescription in the 180 days prior to cohort entry, and those with missing unique identifiers. Individuals were assigned to two exposure groups; 1) Individuals newly initiating methadone, and 2) Individuals newly initiating buprenorphine/naloxone. We defined ongoing treatment on the basis of successive refills for the same medication within 30 days. The primary outcome was fatal or non-fatal opioid overdose using hospitalization visits and coronial records. Secondary outcomes included number of outpatient visits for OUD, and time to receipt of a 7-day take-home supply. We used Cox Proportional Hazards regression and Poisson models to compare outcomes between treatment groups.

Results: After 1 year, 45.6% of people initiating methadone and 29.6% of those initiating BUP continued treatment. Those initiating BUP had a similar risk of opioid overdose (adjusted Hazard Ratio (aHR) 0.85, 95% CI 0.62-1.17), but a lower risk of opioid overdose while on treatment (aHR 0.59, 95% CI 0.39-0.88). Compared to those starting methadone. Those treated with BUP also had a lower rate of outpatient visits for OUD (adjusted Rate Ratio 0.74, 95% CI 0.72-0.76) and were more likely to receive a weekly take-home dose over follow-up (aHR 2.63, 95% CI 2.43-2.85).

Conclusions: There are important differences in the risk of overdose and requirements for frequent healthcare encounters for people starting treatment with methadone and BUP, that can be explained by their differences pharmacologically, and in their models for delivery.

5098 | Dupilumab treatment trends among patients with atopic dermatitis

Maria Schneeweiss and Sebastian Schneeweiss
Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background: Dupilumab is the first systemic biologic immunomodulating agent specifically approved for the treatment of severe atopic dermatitis (AD) in the US. Its use pattern is unknown.

Objectives: This study sought to characterize systemic treatment patterns among patients with AD since the approval of dupilumab.

Methods: We used longitudinal claims data from commercially insured patients in the US, from January 2017 through July 2019. We identified patients of all ages diagnosed with AD, who escalate treatment to a systemic agent, *i.e.*, dupilumab, methotrexate, mycophenolate, cyclosporine or azathioprine. Cohort entry date was the first use of a systemic treatment for AD defined as not having used any systemic treatment during the 180 days before cohort entry. We excluded patients with the following: (1) less than 180 days of continuous enrollment before cohort entry, (2) less than at least 2 diagnoses of AD within 180 days prior to initiating systemic treatment or (3) a range of non-AD conditions that have an indication for treatment with the systemic agents of interest.

Results: We identified 690 patients with AD who were completely naïve to systemic treatment and started treatment to a systemic agent after March 1, 2017. 61% started on dupilumab, 16 % on methotrexate, 15% on cyclosporine, 5% on mycophenolate, 3% on azathioprine and 0.2% started on cyclosporine plus dupilumab. The first change from the initial systemic agent includes 97% stopped systemic treatment, 1% switched to dupilumab, 2% switched to dupilumab plus either cyclosporine, mycophenolate, or methotrexate. The second change includes 9% stopped systemic treatment, 28% switched to dupilumab, 39% to cyclosporine, 9 % to mycophenolate, 8% to azathioprine, and 6% to methotrexate. 3 months after initial treatment with a systemic treatment 25% of patient had discontinued treatment, 62% used dupilumab, 6% methotrexate, 3% cyclosporine, 2% mycophenolate, 1% azathioprine, 1% used dupilumab plus either cyclosporine, methotrexate, azathioprine, or mycophenolate. After 6 months, 49% of patients had discontinued treatment, 42% used dupilumab and after 1 year, 77% of patients had discontinued treatment, and 20% used dupilumab.

Conclusions: Among those patients with AD who started a systemic treatment the proportion of dupilumab initiators was surprisingly high shortly after its initial marketing. It was also the preferred 2nd and 3rd line treatment although absolute numbers are still small.

5104 | Secular trend and determinants of hydroxyurea use among commercially insured adults with sickle cell disease, 2005-2018

Motomori O. Lewis and Yu-Jung Jenny Wei
University of Florida, Gainesville, FL

Background: Hydroxyurea is the principal disease-modifying therapy to prevent vaso-occlusive crisis (VOC) and acute chest syndrome in patients with sickle cell disease (SCD). For adults with SCD, treatment is often stymied by the transition from childhood to adulthood, which introduces challenges in provider access, healthcare coverage, and disease severity. Though treatment patterns in children have been well studied, limited data exist on recent trends in hydroxyurea uptake in this vulnerable adult population.

Objectives: This study aims to determine the annual prevalence, trend, and determinants of hydroxyurea use among adults with SCD.

Methods: We conducted a multi-year, cross-sectional study using the 2005-2018 IBM MarketScan administrative claims database of a commercially insured US population. The study sample included adults aged 18 to 64 years who had 1) at least one inpatient visit, or 2 outpatient visits at least 30 days apart with an ICD-9/10 diagnosis for SCD; and 2) continuous enrollment in health and drug benefits 6 months before (baseline) and 6 months after (follow-up) the first SCD diagnosis in a given year. We excluded patients with sickle cell trait, malignant cancer, chemotherapy, bone marrow transplant, or solid organ transplant within the baseline period. Hydroxyurea use was measured by at least one prescription fill during follow-up. The trend in prevalence and determinants of hydroxyurea use were evaluated with a multivariable modified Poisson regression model.

Results: We identified 12,155 adults with SCD—62.1% were females and 36.2% were between 18-29 years of age. Of this sample, 14.3% received hydroxyurea. Use of hydroxyurea increased significantly between 2005 and 2018 (adjusted prevalence relative ratio (PRR)

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

= 1.39; 95% confidence interval (CI) = 1.19, 1.62). Females were less likely to receive hydroxyurea than males (PRR = 0.79; 95% CI = 0.73, 0.85). Individuals with at least one hospitalization for VOC in the baseline period were more likely to receive hydroxyurea than those without any hospitalizations for VOC (PRR = 1.99; 95% CI = 1.87, 2.11).

Conclusions: Among US commercially insured adults diagnosed with SCD, hydroxyurea uptake increased over time, but its prevalence remains low. Further studies are warranted to assess the impact of not having hydroxyurea in adults with SCD.

5137 | Prevalence, patterns, and risk factors of psychotropic polypharmacy among individuals with depressive disorder in Mainland China: A cross-sectional analysis based on a National Health Insurance database in 2015

Jingyuan Zhang, Guoxu Wei, Xiaodong Guan and Luwen Shi
Peking University, Beijing, China

Background: Psychotropic polypharmacy is reported common in the practice for individuals with depressive disorder, despite the limited supporting evidence and increased risk for adverse drug reactions and drug-drug interactions. The current status in China is largely unknown.

Objectives: To investigate the prevalence, patterns, and risk factors of psychotropic polypharmacy among individuals with depressive disorder in mainland China.

Methods: A cross-sectional analysis was conducted based on China's National Survey of Medical Service Utilization for Basic Medical Insurance Beneficiaries in 2015. Individual's demographic, diagnostic, and drug utilization information were extracted. International Classification of Diseases 10th Revision (ICD-10) was applied to identify persons with depressive disorder in 2015. According to the Anatomical Therapeutic Chemical classification system 4^{th} level, psychotropic polypharmacy was defined as the receipt of ≥2 psychotropic drugs from different classes in at least one medical encounter in 2015. Logistic regression was employed to determine the risk factors associated with psychotropic polypharmacy.

Results: 2337 (44.5%) out of 5240 individuals with depressive disorder were exposed to multiclass psychotropic polypharmacy in 2015. The most common psychotropic polypharmacy was selective serotonin reuptake inhibitors (SSRI) with benzodiazepines derivatives (21.1%), followed by SSRI with antipsychotics such as diazepines, oxazepines, thiazepines and oxepines (9.3%), other antidepressants with benzodiazepines derivatives (8.3%), and combinations of SSRI with other antidepressants (7.4%). Results of Logistic regression showed that adults (OR 3.61, 95%CI 1.73-7.83) and elderly patients (OR 3.01, 95%CI 1.44-6.57), individuals with inpatient encounters (OR 7.67, 95%CI 6.31-9.36), or those with more than three hospital visits (OR 3.39, 95%CI 2.99-3.85) were far more likely to receive psychotropic polypharmacy, while those who had a job (OR 0.42, 95%CI 0.33-0.53) or with somatic chronic conditions (OR 0.40, 95%CI 0.31-0.53) were less likely to be exposed to psychotropic polypharmacy.

Conclusions: Psychotropic polypharmacy among persons with depressive disorder is common in China, despite limited evidence of risks and benefits. Particular attention is required for adults with more intense, but not optimal medical utilization.

5147 | Utilization patterns of multiple sclerosis medications in Saudi Arabia: A cross-sectional retrospective study

Zakiyah Alkherb, Almaha Alfakhri, Maha Alrasheed and Tariq Alhawassi
College of Pharmacy, King Saud University, Riyadh, Saudi Arabia

Background: Multiple sclerosis (MS) is a chronic disease of the central nervous system. Although there is no cure for MS, several disease-modifying drugs (DMDs) are available. Data on the utilization patterns of DMDs among patients with MS in Saudi Arabia are limited.

Objectives: To describe treatment patterns in patients with MS in Saudi Arabia.

Methods: A cross-sectional retrospective study was conducted in a large tertiary university hospital in Riyadh, Saudi Arabia. Study data were derived from the hospital electronic information system during the period from June 9, 2019 to July 25, 2019. Patients age 18 years and older with a documented MS diagnosis who received at least one of the DMDs during the period from 2016 to 2018 were included. A number of demographic and clinical characteristics were evaluated. DMDs used as initial treatment were evaluated and medication discontinuation or switching were assessed. Comorbid conditions and the use of concomitant medications were identified. Categorical variables were summarized by frequency and percentage. Continuous variables were reported as mean and SD. All analysis was conducted using SPSS version 22.

Results: A total of 422 MS patients were included. The mean age was 34.4±9.40 years and 70.9% were females. The majority of patients (48.8%) had a diagnosis Relapsing-remitting MS subtype, however, 46.2% of patients with no subtype documentation. Interferon was the most commonly prescribed initial treatment in 77.49% of patients, followed by Fingolimod and Natalizumab with (11.84, 6.87%) respectively. More than half of the patients (59.72%) remained on their initial treatment and did not require treatment alteration and were less likely to have comorbid conditions (55.2%). The most common reasons for switching or stopping initial treatment were adverse drug reactions, followed by compliance issues, then disease progression, equally (34.7, 18.82 and 17.06%) respectively. Interferon initiators were more likely to remain on their medication (69.84%) and less likely (80.4%) to have comorbid conditions.

Conclusions: Most MS patients started on interferon and more likely required no treatment alteration. The practice is not based on local guidelines. Comorbidities were treated rather than the MS itself.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. Geriatric Pharmacoepidemiology

55 | Oral anticoagulants and risk of acute liver injury in patients with nonvalvular atrial fibrillation: A propensity-weighted nationwide cohort study

Géric Maura[1], Marc Bardou[2], Cécile Billionnet[1], Alain Weill[3], Jérôme Drouin[3] and Anke Neumann[3]

[1]French National Health Insurance (Caisse Nationale de l'Assurance Maladie/Cnam), Paris, France; [2]Clinical Investigation Center, Clinical Epidemiology/Clinical Trials Unit, Dijon-Bourgogne University Hospital, Dijon, France; [3]EPI-PHARE Epidemiology of Health Products, French National Agency for Medicines and Health Products Safety (ANSM) and French National Health Insurance (Cnam), Saint-Denis, France

Background: Insufficient real-world data on acute liver injury (ALI) risk associated with oral anticoagulants (OACs) exist in patients with nonvalvular atrial fibrillation (NVAF), especially in patients with no prior liver disease (LD) and in those with a history of chronic alcoholism.

Objectives: To compare the 1-year risk of serious ALI between each non-vitamin K antagonist (VKA) oral anticoagulant (NOAC: dabigatran, rivaroxaban, apixaban) and VKAs.

Methods: Using data of the French national healthcare database (Régime Général, 54 million beneficiaries), a propensity-weighted nationwide cohort study was performed in NVAF patients initiating OACs from 2011 to 2016, considering three different populations: patients (i) with no prior LD as main population, (ii) with prior LD, (iii) with a history of chronic alcoholism. A Cox proportional hazards model was used to estimate the hazard ratio (HR) with 95% confidence interval (95%CI) of serious ALI (hospitalised ALI or liver transplantation) for each NOAC versus VKA.

Results: In patients with no prior LD (N=434,015), 218 experienced an ALI. Dabigatran and apixaban new users were not at increased risk of serious ALI compared to VKA initiation (adjusted HR: 1.17 [95%CI 0.79-1.75] and 0.82 [0.53-1.25], respectively) unlike rivaroxaban new users (1.41 [1.05-1.91]). This latter association was no longer observed in the sensitivity analyses (propensity score trimming, weight truncation) as it was mainly due to a very small number of patients treated contrary to the prediction. No increased risk was observed in patients with prior LD (N=12,961; 82 experienced an ALI). In patients with chronic alcoholism history (N=13,173; 68 experienced an ALI), only those initiating dabigatran were at increased risk of serious ALI compared to VKA (2.88 [1.74-4.76]). A control outcome (a proxy for elevation of transaminases) suggested that differential clinical follow-up between groups might partly explain this association (no regular blood monitoring needed for NOAC patients in contrast with VKA patients).

Conclusions: The results of this cohort study do not suggest an increased risk of ALI in NOAC versus VKA patients with NVAF during the first year of treatment.

61 | Population based prevalence of selected high priority prescribing cascades among patients with Alzheimers disease and related dementia

Sonal Singh[1], Noelle Cocoros[2], Kevin Haynes[3], Vinit Nair[4], Inna Dashevsky[5], Thomas Harkins[6], Paula Rochon[7], Richard Platt[8], Sybil Crawford[1], Kathleen Mazor[1], Kathryn Anzuoni[1], Sarah Bloomstone[1] and Jerry Gurwitz[1]

[1]University of Massachusetts Medical School & Meyers Primary Care Institute, Worcester, MA; [2]Harvard Medical School and Harvard Pilgrim Healthcare Institute, Boston, MA; [3]HealthCore, Wilmington, DE; [4]Humana Inc, Louisville, KY; [5]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [6]Humana Healthcare Research Inc, Miami, FL; [7]Women's College Research Institute University of Toronto, Toronto, ON, Canada; [8]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA

Background: Prescribing cascades (PCs) occur when a healthcare provider prescribes a second, potentially unnecessary drug therapy to address the side effect of a drug. Population based estimates of PCs among patients with Alzheimer's disease and related dementias (ADRD) are limited.

Objectives: We estimated the incidence of Calcium channel blocker-diuretic (CCB-diuretic) and antipsychotic/antiemetic-antiparkinsonism drug PC among older adults treated for ADRD in two large US health plans

Methods: We identified members aged 50+ who had been treated with an ADRD drug in the 365 days prior to or on Jan 1, 2017. Participants were enrolled in medical and pharmacy coverage for 1 year before and through cohort entry date, bridging enrollment gaps up to 45-days. We excluded participants with an institutional stay encounter and censored members based on first of: disenrollment from medical or pharmacy coverage, death, or end of data. We identified incident and prevalent CCB use and identified incident diuretic use separately among both incident and prevalent CCB users. Incident diuretic use was defined as diuretic use during day 8 through day 365 of CCB use after a washout period of 183 days. Similar methods were used to identify the antipsychotic/antiemetic-antiparkinsonism PC.

Results: There were 121,538 participants with ADRD eligible for inclusion. Approximately 62% were female, with a mean age of 79.5 (SD ± 8.6). Their Combined comorbidity index, a measure of comorbidity was 3 (SD ± 2.7). The mean number of generic drugs used was 9.2 (SD ± 4.9). Overall 2.1% of the ADRD cohort experienced the CCB-diuretic PC with 1586 incident diuretic users among 36,462 prevalent CCB users (4.3%) and 161 incident diuretic users among 3304 incident CCB users (4.8%). Overall 0.3 % of the ADRD cohort experienced the anti-psychotic/antiemetic-antiparkinsonism PC. There were 306 incident antiparkinsonism drug users among 20,746 prevalent antipsychotic/antiemetic drug users (1.4%); and 36 incident antiparkinsonism drugs users among 4534 incident antiparkinsonism/antiemetic users (0.8%).

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: Among two large nationally representative health plans in the United States, the burden of CCB-diuretic and anti-psychotic/antiemetic-antiparkinsonism PC was low. Administrative databases can be used to determine the burden of prescribing cascades.

131 | Potentially inappropriate use of non-steroidal anti-inflammatory drugs in the general older German population

Thi Ngoc Mai Nguyen[1,2], Dana Clarissa Laetsch[2] and Ben Schöttker[2,1]
[1]*Network Aging Research, University of Heidelberg, Heidelberg, Germany*; [2]*Division of Clinical Epidemiology and Aging Research, German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: Non-steroidal Anti-inflammatory Drugs (NSAIDs) are listed as potentially inappropriate drugs (PIM) for adults aged 65 years and older in all frequently used PIM lists due to their negative risk-benefit profile in this population. However, these lists strongly differ in listed active substances and circumstances, in which NSAIDs could be indicated and thus should not be considered as PIM. So far, few studies compared different PIM lists, and none has focused on NSAIDs.
Objectives: The aims of this study were to compare the differences in the prevalences of NSAIDs - PIM use in a sample of the general older German population according to the recommendations of 5 PIM lists: Beers criteria, PRISCUS list, the EU(7)-PIM list, the STOPP criteria and the FORTA list and to identify the determinants of NSAIDs - PIM use.
Methods: We conducted a cross-sectional survey using the 14-year follow-up data from a population-based cohort study from Germany. Participants aged 65 years or older who reported the use of NSAIDs were included (n=287). Drug data were obtained according to the "brown bag method," which ensures the inclusion of over-the-counter preparations. To detect whether an NSAID is also a PIM, the 2019 Beers criteria, the 2015 STOPP criteria, the EU(7)-PIM list, the PRISCUS list, and the FORTA list were used. Multivariate logistic regression models were used to assess the determinants of NSAIDs-PIM use according to the 5 different PIM lists. Two-sided p-values < 0.05 were considered to be significant.
Results: Prevalence of NSAIDs -PIM use varied greatly among the PIM definitions used: STOPP criteria (54.7%), Beers criteria (45.6%), EU(7)-PIM list (29.6%), FORTA list (21.3%) and PRISCUS list (3.5%). 27% of all NSAIDs -PIM users would be only identified by one list, whereas none of them would be identified by all five lists. Determinants of NSAIDs -PIM use also varied by the PIM list used. For example, for the STOPP criteria, cardiovascular disease (CVD), chronic kidney disease (CKD), gout and peptic ulcer disease (PUD) were statistically significantly associated with the use of NSAIDs - PIM among NSAIDs users (Odds ratios [95% confidence intervals]: 4.91 [2.46, 10.24], 12.51 [5.28, 34.11], 2.22 [1.01, 5.04] and 5.46 [2.16, 15.47], respectively).
Conclusions: The recommendations of currently available PIM lists for NSAIDs highly vary and there is an urgent need for harmonization in order to provide better guidance to physicians for the prescription of NSAIDs for older adults.

2334 | Concomitant use of benzodiazepines and opioids and risk of fractures in older adults with chronic non-cancer pain in South Korea, 2011-2015: A nested case-control study

Ye-Jin Kang, Hyun-Ji Koo, Min-Taek Lee, Seung-Hun You, Myo-Song Kim, Ji-hye Seo and Sun-Young Jung
Chung-Ang University, Seoul, Republic of Korea

Background: Although benzodiazepines (BZDs) and opioids are each associated with an increased risk of fractures, the level of the risk associated with the combined use of these drugs is uncertain.
Objectives: To investigate the relationship between the combined use of BZDs and opioids with the risk of fractures in older patients with chronic non-cancer pain.
Methods: In this nested case-control study, we used the National Health Insurance Service-National Sample Cohort database of Korea from 2002 to 2015. Among osteoarthritis or low back pain patients (>64 years), cases were defined as the incident diagnosis of hip, humerus or forearm fracture between 2011 and 2015. For each case, up to four controls were matched using age (within 5 years), sex, and cohort entry date. We categorized BZDs exposure windows as current, recent and past use and defined current BZDs exposure as use within 30 days before index date, recent BZDs exposure as use within 31-90 days before index date and past BZDs exposure as use within 91-365 days before index date. We categorized each exposure to BZDs with and without opioids. We estimated adjusted odds ratios (aORs) and 95% confidence intervals (CIs) of combined use of BZDs and opioids using conditional logistic regression analysis, adjusting for concomitant diseases and concomitant medications. We also performed subgroup analysis according to age groups, type of fracture, the presence of osteoporosis and an antidepressants prescription.
Results: We identified 3,487 cases and 12,350 controls. Among them, 81.8% of cases and 82.0% of controls were female, and mean ages were 75.2 (±6.5) and 74.7 (±6.0) years respectively. The aORs (95% CIs) for current use of BZDs + opioids and BZDs alone were 1.34 (1.15-1.57) and 1.04 (0.91-1.17), each compared to non-use. In subgroup analysis of hip fracture, aORs for current use of BZDs + opioids and only BZDs were 1.55 (1.16-2.06) and 1.04 (0.82-1.33) respectively. The aORs for current use of BZDs + opioids were 1.25 (1.03-1.51) in patients with osteoporosis, and 1.06 (0.89-1.25) in patients without osteoporosis. Finally, the aORs for current and past use of BZDs + opioids in patients had a prescription of antidepressants were each 1.44 (1.21-1.72) and 1.31 (1.05-1.64). There was no association with these outcomes in patients without a record of antidepressants.
Conclusions: Concomitant use of BZDs and opioids was associated with an increased risk of fractures in older adults with chronic non-cancer pain.

2414 | Nonselective beta-blocker eyedrops and the risk of fall-related injuries: A danish nationwide active comparator, new user propensity score matched cohort study

Sidsel Arnspang Pedersen[1], Mette Reilev[1], Lars Christian Lund[1], Daniel Henriksen[1], Bjarke Viberg[2] and Jesper Ryg[3]
[1]*University of Southern Denmark, Department of Clinical Pharmacology and Pharmacy, Odense, Denmark;* [2]*Lillebælt Hospital, Kolding, Denmark;* [3]*University of Southern Denmark, Department of Clinical Research, Odense, Denmark*

Background: Falls in older patients represent a major public health issue. Risk factors for falls are multifactorial and include the use of commonly prescribed medication such as betablockers. Timolol is a non-selective beta-blocking eye drop agent used in the treatment of glaucoma. Due to high systemic absorption, the use of timolol eye drops may cause alterations in heart rate and rhythm potentially increasing falls risk. However, this has not been investigated in older adults.

Objectives: To investigate the risk of injurious falls in older patients using topical non-selective betablockers compared to prostaglandin analogues.

Methods: We conducted an active comparator, new user cohort study using information on redeemed prescriptions and hospital discharge diagnoses from the Danish nationwide registries. We identified all patients ≥65 years, who initiated either timolol eye drops or topical prostaglandin analogues and matched them in a 1:1 ratio, based on a high-dimensional propensity score. The **primary outcome was injurious falls (defined as** contusion, wounds and fractures other than hand and feet**) within 90 days after a first prescription of either drug. Fall-related fractures was used as a secondary outcome.**

We obtained incidence rate ratios (IRR), incidence rate differences (IRD), and the number needed to treat to harm one additional patient (NNTH) for both unmatched and matched cohorts.

Results: In total, 40,420 older adults were identified as users of timolol and 55,754 as users of prostaglandin analogues. Of these, 43% were male and the median [IQR] age was 75 [70-80] years. For the unmatched cohort, the IRR of injurious falls was 1.20 (95% CI 0.98-1.49), IRD was 4 (0-8) cases per 1000 person years, and NNTH was 1,695 for one year of treatment with timolol compared to prostaglandin analogues. In the propensity score matched cohort we identified 28,431 first users of timolol eye drops and 28,431 users of prostaglandin analogues. The IRR of injurious falls was 0.96 (95%CI 0.73-1.27), IRD -1 (95% CI -6 to 5) per 1000 person years, and a number needed to treat for one year to prevent one additional case of 12,500. For fall-related fractures, the IRR was 1.30 (95% CI 0.96-1.76), IRD of 4 cases per 1000 person years and a NNTH of 252.

Conclusions: We found no increased risk of injurious falls after initiation of timolol eyedrops in an older Danish population.

2536 | Prescription drugs among dementia patients with behavioral disturbance

Wenjun Zhong, Xinyue Liu, Tiffini Voss, Sauzanne Khalilieh, Rezaul Karim Khandker1 Khandker, Edward Bortnichak and Kai-Li Liaw
Merck, North Wales, PA

Background: Behavioral disturbance (BD) in dementia patients is common and requires many healthcare resources, but there have been no FDA approved medications for this indication.

Objectives: This study examined real-world medication use in dementia patients with BD to inform future new drug investigational studies.

Methods: A cross-sectional study was conducted using Truven MarketScan Commercial and Medicare Supplemental database for outpatient medication use in Oct 2015-Dec 2018. Patients with two outpatient or one inpatient dementia diagnosis were identified through ICD-10-CM codes, and the first event of BD (including agitation, aggression, psychosis, delirium, and wandering) at or after the dementia diagnosis was identified through ICD-10-CM codes as the index BD. Medications prescribed before (days' supply should cover BD index date) and after BD index date (within 6 months) were identified through National Drug Code. All the medications used in this population were counted and the frequencies were reported both in therapeutic classes and in generic names.

Results: Among 232,921 patients with dementia during Oct 2015-Dec 2018, 83,024 (36%) had at least one BD event after dementia diagnosis during the same time period. Of these BD patients, the mean (standard deviation) age was 81 (13) years at the time of index BD (90% of the population were >=65 years, and 50% were >=85 years); about 60% were female. Among them, 85% (n=70,481) received prescriptions before or after the index BD event. Top 5 prescription classes were antidepressants (60%), antihyperlipidemic drugs (45%), beta blockers (40%), parasympathomimetic drugs (39%) and tranquilizers/antipsychotic drugs (37%). Top 5 drugs prescribed before BD index event were donepezil (20%), levothyroxine (18%), atorvastatin (16%), memantine (15%), and amlodipine (13%). Top 5 drugs prescribed after BD index event (within 6 months) were donepezil (27%), levothyroxine (21%), memantine (21%), atorvastatin (20%), and quetiapine (19%). Other central nervous system drugs (top 5 CNS) prescribed after BD index event were sertraline (13%), mirtazapine (12%), trazodone (12%), lorazepam (11%) and escitalopram (10%).

Conclusions: Patients with dementia and BD were an older population. A large proportion of them were exposed to prescription medications including CNS drugs such as antidepressants and antipsychotics. There is an unmet medical need in this population since this patient population is susceptible to the side effects of antidepressants and antipsychotics. This study provided real-world medication use data for future new drug investigational studies for dementia patients with BD.

2599 | Anticholinergic and sedative drug load among medicare beneficiaries

Shahar Shmuel[1], Virginia Pate[1], Marc J. Pepin[2], Janine C. Bailey[2], Laura C. Hanson[3,4], Til Stürmer[1], Rebecca B. Naumann[1,5], Yvonne M. Golightly[1,5,6,7], Danijela Gnjidic[8] and Jennifer L. Lund[1]

[1]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Durham Veteran Affairs (VA), Durham, NC; [3]Division of Geriatric Medicine & Palliative Care Program, University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Sheps Center for Health Services Research, University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Injury Prevention Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [7]Division of Physical Therapy, University of North Carolina at Chapel Hill, Chapel Hill, NC; [8]Sydney Pharmacy School, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia

Background: Medications with anticholinergic and sedating properties are widely used among older adults despite strong evidence of their harm. The Drug Burden Index (DBI), a clinical screening tool that incorporates dose and cumulatively measures these properties across drug classes, may identify patients at high risk of physical and cognitive function-related adverse events. However, the DBI has been studied mainly outside the US, and not using US Medicare claims.

Objectives: We developed an updated US-based DBI drug list and operationalized the DBI for Medicare claims, and used this framework to (1) measure the monthly distribution based on mean daily DBI, (2) identify patient-level predictors of high mean daily DBI exposure, and (3) describe temporal trends in the prevalence of several DBI thresholds.

Methods: We screened medications for DBI properties and operationalized the DBI for Medicare claims. We then conducted a retrospective cohort study of a 20% random, nationwide sample of 4,137,384 fee-for-service Medicare beneficiaries aged 66+ years (134,757,039 person-months) from 2013 to 2016. We measured the monthly distribution based on mean daily DBI, categorized as (1) >0 vs. 0 (any use) and (2) 0, 0<DBI<=1, 1<DBI<=2, and DBI>2, and examined temporal trends. We described patient-level factors (e.g., demographics, healthcare use, and health status) associated with high (>2) versus low (0<DBI<=1) DBI exposure.

Results: The person-month distribution of the mean daily DBI was: 58.1% DBI=0, 29.0% 0<DBI<=1, 9.3% 1<DBI<=2, and 3.7% DBI>2. The estimated annual period prevalence of any (>0) DBI exposure decreased slightly over the study period, while the monthly point prevalence was stable. Predictors of high monthly DBI exposure (>2) included certain indicators of increased healthcare use (e.g., high number of drug claims), white race, younger age, low-income subsidy, frailty, and a psychosis diagnosis code.

Conclusions: This study operationalized the DBI in Medicare claims and described patterns of DBI exposure over time. The predictors of high monthly DBI exposure can be used to inform discussions between patients and providers about medication appropriateness and potential de-prescribing. Future studies should assess the association between the DBI and adverse events among Medicare patients.

2611 | The risk of fractures, acute myocardial infarction, atrial fibrillation and ventricular arrhythmia in geriatric patients exposed to promethazine

Maurizio Sessa, Dr[1], Annamaria Mascolo[2], Kim Dalhoff, Dr[3] and Morten Andersen, Dr[1]

[1]University of Copenhagen, Copenhagen, Denmark; [2]University of Campania "L. Vanvitelli", Napoli, Italy[3]Bispebjerg and Frederiksberg University Hospital, Copenhagen, Denmark

Background: The risk of development of adverse drug reactions to first-generation anti-histamine receptors 1 (H1) is increased in the geriatric population due to physiological changes associated with aging and the age-associated high number of potentially interacting medications. From more than two decades, the American Geriatrics Society has recommended that first-generation anti-H1 with enhanced anticholinergic activity (i.e. promethazine) should be avoided in individuals aged 65 or more. However, to date, on an international perspective, evidence helpful for health policy-makers such as studies from routine clinical practice investigating the safety profile of promethazine in comparison to other therapeutic alternatives are scarce and needed. Additionally, it is unknown if the risk of experiencing these clinical outcomes is extended to all geriatric patients independently of their clinical and socio-demographic characteristics or if the risk is circumscribed to specific sub-populations (i.e. patients with a specific set of comorbidities).

Objectives: This study aimed to compare the risk of fractures, acute myocardial infarction, atrial fibrillation, and ventricular arrhythmia among Danish citizens aged ≥ 65 which were new users of promethazine or domperidone, triazolam, loratadine, and betahistine. Secondly, the study aimed to perform a risk stratification to identify the most relevant predictors for the study outcomes.

Methods: The study period was 01/01/2015 to 31/12/2016. The data sources were the Danish registers. Each patient was followed for 90 days. A logistic regression model was used to compute the unadjusted and adjusted odds ratios (OR), and a conditional inference tree was used to identify the most relevant predictors for the study outcomes.

Results: Promethazine had a higher risk of hospitalization for atrial fibrillation than loratadine and betahistine (OR 1.58; 95% CI 1.07-2.63 and OR 3.22; 95% CI 1.69-7.14, respectively). For fractures, acute myocardial infarction, and ventricular arrhythmia hospitalizations, no statistically significant differences were found among drugs under investigation. The medical history of cardiac arrhythmia (OR 4.14; 95% CI 2.94-5.78, p<0.0001) was the most relevant predictor for atrial fibrillation hospitalizations.

Conclusions: This study found an increased risk of atrial fibrillation hospitalization among promethazine users, and the risk was higher among patients with prior cardiac arrhythmia.

2612 | Metoprolol versus carvedilol in patients with heart failure, chronic obstructive pulmonary disease, diabetes mellitus, and renal failure

Maurizio Sessa[1], Daniel B Rasmussen[2], Magnus T Jensen[3], Kristian Kragholm[4], Christian-Torp Pedersen[5] and Morten Andersen[1]
[1]*University of Copenhagen, Copenhagen, Denmark;* [2]*Naestved Hospital, Næstved, Denmark;* [3]*Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark;* [4]*Aalborg University Hospital, Aalborg, Denmark;* [5]*Nordsjaellands Hospital, Hillerød, Denmark*

Background: In heart failure patients, it is not uncommon to find patients with heart failure, chronic obstructive pulmonary disease, and diabetes mellitus, but currently, none of the most authoritative clinical practice guidelines provide recommendations on which β-blocker should be used. A recent study suggested that physicians prefer carvedilol to other β-blockers in this clinical scenario. However, evidence supporting this clinical practice is missing.

Objectives: This study aims to compare the survival and the risk of heart failure, chronic obstructive pulmonary disease, diabetes mellitus, hypoglycemia, and renal failure hospitalizations in geriatric patients with heart failure, chronic obstructive pulmonary disease, and diabetes mellitus exposed to carvedilol or metoprolol. Additionally, this study aims to identify the most import predictors for these study outcomes by using an artificial intelligence technique and to evaluate subpopulations of interest such as patients with concurrent lipid disorder or chronic kidney disease.

Methods: Data sources were Danish administrative registers. Patients aged ≥65 and having heart failure, chronic obstructive pulmonary disease, and diabetes mellitus were followed for 1 year from the first β-blocker prescription redemption. Patients' characteristics were used to 1:1 propensity score match carvedilol and metoprolol users. A Cox regression model was used to compute the hazard ratio (HR) of study outcomes. For statistically significant associations, a conditional inference tree was used to assess predictors most associated with the outcome.

Results: In total, 1,424 patients were included. No statistically significant differences were observed for survival (HR 0.86; 95% confidence interval [CI] 0.67 to 1.11, p = 0.240) between carvedilol/metoprolol users. The same applied to chronic obstructive pulmonary disease (HR 0.88; 95% CI 0.75 to 1.05, p = 0.177), diabetes mellitus (HR 0.95; 95% CI 0.82 to 1.10, p = 0.485), hypoglycemia (HR 0.88; 95% CI 0.47 to 1.67, p = 0.707), and RF (HR 1.25; 95% CI 0.93 to 1.69, p = 0.142) hospitalizations. Carvedilol users had a 38% higher hazard then metoprolol users of heart failure hospitalization during the follow-up period (HR 1.38; 95% CI 1.19 to 1.60, p <0.001). Artificial intelligence identified carvedilol exposure as the most important predictor for heart failure hospitalization.

Conclusions: This study found an increased risk of heart failure hospitalization for carvedilol users compared with metoprolol users with this triad of diseases.

2652 | Identifying frequent drug combinations associated with delirium in older adults: Application of association rules method to a case-time-control design

Prasad Nishtala[1] and Te-yuan Chyou[2]
[1]*University of Bath, Bath, United Kingdom;* [2]*University of Otago, Dunedin, New Zealand*

Background: Older adults are at an increased risk of delirium because of age, polypharmacy, multiple comorbidities and acute illness.

Objectives: The aim of this case-time-control study was to apply association rule analysis to ascertain drug combinations contributing to the risk of delirium in adults aged 65 years and older.

Methods: We sourced a nationwide representative sample of New Zealander's aged ≥65 years from the pharmaceutical collections and hospital discharge information. Prescription records (2005-2015) were obtained from New Zealand pharmaceutical collections (Pharms). Medication exposures were coded as binary variables at the individual drug level. All medications, including antimicrobials, antihistamines, diuretics, opioids, non-steroidal anti-inflammatory medications were considered as drugs of interest. The first-time coded diagnosis of delirium was extracted from the National Minimal Dataset (NMDS). A unique patient identifier linked the prescription dataset to the event dataset, to set up a case-time-control cohort, indexed at the first delirium event. Association rules were then applied to identify frequent drug combinations in the case and the control periods (l-day with a 35-day washout period) that are statistically associated with delirium, and the association was tested by computing a time-trend adjusted matched odds-ratio (MOR) and its 95% confidence interval (CI).

Results: We identified 26343 individuals (mean age 84.3) from 2005 to 2015 with incident delirium and exposed to at least one prescription record. Our combined association rule and case-time-control analysis identified several drug classes including antipsychotics, benzodiazepines and opioids, that are associated with delirium. Our analysis also identified frequently used drug combinations that are associated with delirium. Examples include quetiapine and furosemide (MOR=6.17; 95%CI= [2.05-18.54]), haloperidol (MOR=4.81; 95%CI= [3.16-6.69]), furosemide plus omeprazole plus lorazepam (MOR=3.94; 95%CI= [3.03-5.10]), and fentanyl (MOR=3.46; 95%CI [2.05-9.21]).

Conclusions: Association rules uncovered previously implicated drug classes such as antipsychotics, benzodiazepines and opioids that increase the risk of delirium in older adults. The application of association rule method to a case-time-control design is a novel method to identify chronic effects of medication exposures during the time at risk of an adverse drug event.

3708 | Three strategies to measure frailty and/or complex health needs in real world data: An analysis of UK primary care and hospital linked data

Leena Elhussein, Ying H. E., Danielle E. Robinson, Antonella Delmestri, Victoria Y. Strauss and Daniel Prieto-Alhambra

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Background: Complex health needs and frailty are key confounders in geriatric pharmaco-epidemiology. Although a number of definitions exist, none are formally accepted or adopted in geriatric pharmacoepidemiology. Recent NICE guidelines recommend using primary care electronic health records to identify markers of frailty, including the electronic Frailty Index (eFI). Others have advocated for the measurement of polypharmacy and/or healthcare resource use as alternative methods for the identification of frail patients in routine data.

Objectives: We tested the use of three definitions of frailty, and assessed the overlap between the resulting three cohorts. Sociodemographics, co-morbidity, and common drug/s use were then characterised in the three cohorts.

Methods: All participants aged 65 or older on 1 Jan 2009, registered for 1 year or above were identified from CPRD GOLD, a primary care database including >10 million UK people. Those registered in practices with no linkage to Hospital Episode Statistics (HES) data were excluded. Three cohorts were identified based on the top quintile of three indices measured in the previous year: 1.healthcare resource use defined as the number of unplanned hospital admissions [cohort1], 2.score in electronic frailty index (eFI) [cohort2], and 3.polypharmacy estimated as the number of different drugs prescribed in GP records [cohort3]. Baseline characteristics and overlap between the cohorts were described.

Results: 464,886 participants were eligible for the study, of whom 73,724, 104,885, and 100,965 constituted Cohorts 1, 2 and 3 respectively. 20,741 (4.5%) patients were included in all three cohorts. Mean age (SD) was very similar for all three cohorts (77.0 (7.7), 77.6 (7.4) and 77.2 (7.3) respectively). Cohort 3 had the lowest proportion of males: 38.8% vs. 43.2% in cohort 1 and 41.0% in cohort 2. Preventative medicines, such as, bisphosphonates, statins and diuretics were prescribed to a higher proportion of patients in the three cohorts compared with the background (non-frail) population in the year prior to start (e.g. statins were prescribed to 47.8% in cohort 1 vs. 38.9% in the background population).

Conclusions: All three strategies are feasible for the identification of elderly frail patients in UK data, but the overlap between all three is small. Further research is needed on the best strategy/ies to measure frailty in real world data.

3768 | Negative association between dementia and gout or gout medications using national health insurance service claim database

Kyung Hyun Min, Sang Oh Kang, Ha Rim Yeon and Kyung Eun Lee
Chungbuk National University, Chungchungbugdo, Cheonjusi, Republic of Korea

Background: Uric acid is known to have neuroprotective effect. Gout which is caused by hyperuricemia might have association with dementia.

Objectives: To find out how gout or gout medications affect dementia incidents (overall dementia, Alzheimer's, vascular and others) in elderly Korean patients (≥ 60 years of age).

Methods: We conducted retrospective population-based cohort study using Elderly Cohort from 2002 to 2013 provided by Korean National Health Insurance service (NHIS) claims data. In NHIS-Elderly Cohort, patients with gout were selected as exposure group. In this process, we selected patients with at least two times of gout diagnosis (KCD7 code 'M10') and minimum of 180 days of lag-time between gout and dementia. Index data was assigned as the first date of gout diagnosis. To define as new patients, patients with index date in 2002 were excluded. Non-exposure group was formed by conducting 1 on 5 matching by age and sex. In non-exposure group, index date was assigned randomly between January 1st, 2002 and first diagnosis of dementia or death or end of study. We conducted statistics using cox proportional hazard model. Hazard ratio were adjusted for age, sex, hypertension, diabetes mellitus (type 1&2), dyslipidemia, cardiovascular diseases and Parkinson's disease. To describe the effects of medication (allopurinol, febuxostat and colchicine) regardless of gout itself, we conducted nested case-control study. Dementia patients were selected as case group and 1 on 4 matched non-dementia patients were selected as control group. For statistics, we used multivariate logistic regression. Covariates from analysis above were used for odds ratio adjustment. Primary outcome of this study was adjusted hazard ratio of dementia according to gout status. Secondary outcome was the odds ratio of dementia according to gout medication. All data processing steps and statistics were done using SAS Enterprise Guide 7.1.

Results: Among 558,147 patients registered in NHIS-Senior cohort, 22,718 patients had gout incidents. 20,821 patients out of total 136,308 study population developed any dementia. 2,557 patients (11.26%) and 18,264 patients (16.08%) had dementia incidents for exposure and non-exposure group, respectively. Hazard ratio adjusted by covariates was 0.63 (CI: 0.60-0.66, p<0.0001). Similar tendency is shown for each type of dementia. 7,394 out of 12,784 gout patients (57.8%) were prescribed of gout medication and adjusted odds ratio for dementia was 0.93 (CI: 0.85-1.02, p=0.95).

Conclusions: Gout seems to have negative association with dementia considering covariates.

3784 | The effect of low-dose oral glucocorticoid therapy on osteoporotic fracture risk in patients with rheumatoid arthritis

The Clinical Practice Research Datalink Gold

Frank de Vries[1,2], Annemariek Driessen[1], Andrea Burden[1,3], Patrick Souverein[4], Tjeerd van Staa[2], Joop van den Bergh[5,6] and Shahab Abtahi[1]
[1]*Maastricht University Medical Centre+, Maastricht, Netherlands;* [2]*Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands;* [3]*Institute of Pharmaceutical Sciences, Zurich, Switzerland;* [4]*Utrecht*

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Institute for Pharmaceutical Sciences, Utrecht, Netherlands; [5]Maastricht University Medical Centre+, Maastricht, Netherlands; [6]VieCuri Medical Centre, Venlo, Netherlands

Background: Randomized clinical trials (RCTs) showed that low-dose glucocorticoid (GC) therapy in patients with rheumatoid arthritis (RA) was associated with less bone mineral density (BMD) loss in hand or hip. However, the effect on osteoporotic fractures is not yet clear and observational studies mostly reported contrasting results compared to the BMD studies.

Objectives: To investigate the use of low-dose oral GCs on osteoporotic fracture risk among patients with RA in the UK.

Methods: This was a cohort study including all RA patients aged 50+ from Clinical Practice Research Datalink (CPRD) between 1997-2017. Exposure to oral GCs was stratified into current (<6 months), recent (7-12 months), and past use (>1 year), based on the time since the most recent prescription. Current use was further stratified by average daily and cumulative doses. Time-dependent Cox proportional-hazards models estimated risk of osteoporotic fracture (included hip, vertebrae, humerus, forearm, pelvis, or ribs) in RA patients with current use of low-dose oral GCs (average daily dose ≤7.5mg prednisolone equivalent dose [PED]/d) versus past use. The analyses were statistically adjusted for life-style parameters, comorbidities and co-medications.

Results: Among 15,123 patients with RA (mean age 68.8 years, 68% females), 1,640 osteoporotic fractures occurred. Low-dose oral GC therapy (≤7.5mg PED/d) in RA patients was associated with no increased risk of OP fractures compared with past GC use (adjusted [adj.] hazard ratio (HR) 1.1, 95%CI 0.98-1.3). Only clinical vertebral fractures were associated with low-dose GC therapy (adj. HR 1.6. 95%CI 1.1-2.3). Cumulative GC use ≥1g PED in current users was associated with an increased OP fracture risk (adj. HR 1.2, 95% CI 1.0-1.5). However, low-dose oral GC use (≤7.5mg PED/d) was not associated with an increased risk, regardless of the cumulative dose.

Conclusions: Low-dose GC therapy did not increase the OP fracture risk in RA patients compared with past GC use. Our results are in line with findings from RCTs reporting a similar effect of low-dose GC use on BMD in various anatomical sites. These data does not support additional assessment for OP fracture sites other those of the clinical vertebrae when a RA patient is receiving GCs in low daily doses (≤7.5mg PED/d).

3926 | Potentially inappropriate medication in older adults attended in the emergency department (ED) and their association with ED visits

Marcela Jirón[1], Matías F. Martínez[1] and Luis Herrada[2]

[1]University of Chile, Santiago, Chile; [2]Clinical Hospital at University of Chile, Santiago, Chile

Background: Potentially Inappropriate Medications (PIM) increase the risk of adverse outcomes in older adults. Little is known of the prevalence of PIM according to the 2019 Beers Criteria in older adults attended in the Emergency Department (ED) and their association with ED visits.

Objectives: To determine the prevalence of PIM among older adults attended in the ED and their association with ED visits.

Methods: We conducted a cross-sectional study in a database of randomly selected sample of older adults in an ED at a teaching hospital in Chile from 2015 to 2016. Patients included were aged ≥60 years with a signed informed consent form. Patients with cognitive impairment or severe illness unable to provide informed consent were included only if a caregiver responsible was able to sign in on behalf of the patient. Prevalence of patients with at least one PIM at the admission, during, and at discharge of the ED visit were estimated. An independent pharmacist and an emergency physician assessed potential Adverse Drug Events (ADE) as a cause of ED visit by direct observation. They collected sociodemographic characteristics, clinical and pharmacotherapy profiles of each patient. PIM was defined according to the 2019 Beers Criteria. We identified the association between PIM and ED visits using multiple logistic regression in STATA 15.1.

Results: A total of 298 patients were included. The mean ± SD age was 72.1 ± 8.9 years, 63.8% (n=190) were women, and 45.0% (n=134) of patients were using 5 or more medications (mean 4.6 ± 3.0 drugs/patient). The prevalence of older adults with at least one PIM at the admission, during, and at discharge of the ED visits were 73.2% (95% CI: 68.1-78.2), 51.1% (95%CI: 44.7 - 57.4), and 40.9% (95% CI :33.0 - 48.9), respectively. A 22.6% (95%CI: 21.5 - 30.8) of patients studied were admitted at the ED as a cause of an ADE. PIM according to 2019 Beers Criteria were independently associated with ED visits as a cause of an ADE (adjusted OR 2.2; 95%CI: 1.01 - 4.94; $p<0.05$), controlling by age, sex and number of medications.

Conclusions: PIM is highly prevalent among older adults attended in the studied ED. PIM according to 2019 Beers Criteria are independently associated with ED visits related to an ADR. There is a potential to optimize the older patients' drug safety, and health care utilization by preventing avoidable ADEs.

3951 | Evaluation and comparison of potential over-treatment rates among older adults with type-2 Diabetes in Manitoba using prescription vs dispensation databases

139.1.1. | Sai Krishna Gudi[1], Shawn Bugden[2], Kevin Friesen[1] and Jamie Falk[1]

[1]University of Manitoba, Winnipeg, MB, Canada; [2]Memorial University of Newfoundland, St. John's, NL, Canada

Background: Diabetes is highly prevalent among older adults and significant concerns exist regarding potential over-treatment. Currently, the extent of overtreatment in older adults with type-2 diabetes in Manitoba has not been addressed.

Objectives: To evaluate and compare potential over-treatment related to intensity of glycemic control among older adults with type-2 diabetes across Manitoba using prescription & dispensation data.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: An observational cohort study was conducted using data from Manitoba, Canada from 2010-2017. A cohort extracted from the Manitoba Primary Care Research Network (MaPCReN, a dataset of prescriptions by primary care providers) was linked with corresponding Manitoba Centre for Health Policy (MCHP, a dataset of dispensations of prescriptions by all prescribers) data in order to assess and compare potential over-treatment rates. Patients aged ≥65 years with type-2 diabetes defined by the Canadian Primary Care Sentinel Surveillance Network validated case definition with at least one HbA1c measurement were included. Intensity of glycemic control was assessed in two cross-sectional years (2012, 2016). Over-treatment was defined as an index HbA1c (first recorded HbA1c of the year) of <7% and dispensation of any anti-diabetic medication other than metformin within 3 months before and after index HbA1c. The secondary outcome was contribution of prescriber-type towards the prescription of over-treatment medications in the MCHP database. SAS Version 9.4 was used for all data analyses.

Results: A cohort of 3376 patients (51.8% females, mean age 76.6 years) was identified. Overall rates of potential over-treatment were 10.7% (2012) and 11.1% (2016) (p = 0.67 [95% CI -1.47 to 2.20]), and 20.4% (2012) and 21.5% (2016) (p = 0.37 [95% CI -1.32 to 3.47]), using prescription and dispensation data, respectively. Among potentially over-treated patients, 19.8% in 2012 and 21.5% in 2016 (p = 0.16 [95% CI -0.70 to 4.05]) of over-treatment medications were prescribed by non-general practitioners (i.e., specialists like endocrinologists), using MCHP data.

Conclusions: Rates of potential over-treatment among older adults with type-2 diabetes were found to be remarkably higher in the province of Manitoba using dispensation data (MCHP) compared to provincial primary care prescription data (MaPCReN), with no evidence of rates decreasing over time. Non-GPs contributed to approximately 20% of over-treatment prescriptions which may account for some, of the difference between over-treatment rates between the MCHP and MaPCReN cohorts.

4002 | Systematic review and meta-analysis on the associations of polypharmacy and potentially inappropriate medication with adverse outcomes in older cancer patients

Li-Ju Chen[1,2], Kira Trares[1,2], Dana Clarissa Laetsch[1], Thi Ngoc Mai Nguyen[1,2], Hermann Brenner[1,2] and Ben Schöttker[1,2]

[1]German Cancer Research Center, Heidelberg, Germany; [2]University of Heidelberg, Heidelberg, Germany

Background: Polypharmacy and potentially inappropriate medication (PIM) intake are prevailing in older cancer patients. However, the current evidence regarding their associations with adverse outcomes in older cancer patients has not been summarized.

Objectives: To systematically search, review, appraise, and meta-analyze the currently available evidence from observational studies about associations of polypharmacy and PIM use with all-cause mortality, hospitalization, prolongation of hospitalization, treatment-related toxicity, and postoperative complications.

Methods: A systematic review and a meta-analysis of observational studies reporting associations of polypharmacy or PIM with at least 1 out of 5 pre-defined adverse outcomes in older cancer patients (≥ 60 years) were conducted. PubMed and Web of Science were used to search for relevant studies published between January 1991 and February 2019. Data were pooled by adopting a random-effects model.

Results: 27 publications were included in the systematic review. Meta-analyses could be performed on 23 studies about polypharmacy and 10 studies about PIM. Polypharmacy was found to be significantly associated with all-cause mortality (risk ratio [95% confidence interval]: 1.36 [1.19-1.55]), hospitalization (1.59 [1.18-2.15]), and postoperative complications (1.73 [1.36-2.20]). Associations of polypharmacy with prolongation of hospitalization (1.62 [0.98-2.66]) and treatment-related toxicity (1.25 [0.96-1.64]) were close to statistical significance. In contrast, no statistical significance was found between PIM and any assessed adverse outcome.

Conclusions: Polypharmacy was found to be associated with several adverse outcomes in older cancer patients. However, these results should be interpreted with caution because two-thirds of the studies identified for polypharmacy did not adjust for comorbidity. For PIM, no significant associations were noticed. However, 7 out of 8 included studies applied a prevalent user design and were therefore susceptible to the healthy-user/sick-stopper bias. Further well-designed studies are needed.

4014 | Updated data on potentially inappropriate medications use in older adults in France: A population-based study

Barbara Roux[1,2,3], Pernelle Noize[1,3], Julien Bezin[1,3], Camille Morival[1,3] and Marie-Laure Laroche[2,4]

[1]Bordeaux Population Health Research Center, Team Pharmacoepidemiology, UMR 1219, University of Bordeaux, Bordeaux, France; [2]INSERM UMR 1248, Faculty of Medicine, University of Limoges, Limoges, France; [3]Service de Pharmacologie Médicale, Pôle de Santé Publique, CHU de Bordeaux, Bordeaux, France; [4]Centre of Pharmacovigilance and Pharmacoepidemiology, Department of Pharmacology-Toxicology and Centre of Pharmacovigilance, University Hospital of Limoges, Limoges, France

Background: The use of potentially inappropriate medications (PIM) in the older population remains a public health concern in several countries. Few recently population-based data exists on PIM use in community-dwelling older people in France. Yet their use may be associated with preventable adverse events and significant health costs.

Objectives: To estimate the prevalence and incidence of potentially inappropriate medications (PIM) use in community-dwelling older adults ≥ 65 years in France.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A cross-sectional study was conducted using data from a 1/97th random sample of the French national healthcare reimbursement system (covering 90% of the entire population). Individuals aged ≥ 65 years who were insured between January and December 2016 were included for the estimation of the prevalence of PIM use. Among this population, individuals without PIM dispensing in the previous year were identified for the estimation of the incidence of PIM use. PIM were defined using a revised version of the French Laroche list including medications that should be generally avoided in older adults or that should be avoided depending on dose or duration.

Results: Around half of the 98,568 older adults included (48.4%) were dispensed at least one PIM in 2016. Of these, 60.0% were women, mean age was 76.3 years (SD 8.2) and 82.8% used ≥10 different medications yearly. The most prevalent PIM were proton-pump inhibitors >8 weeks (22.3%), long-acting benzodiazepines (9.2%), anxiolytic benzodiazepines >12 weeks (7.0%), first-generation antihistamines (5.6%), anticholinergic antiemetics (5.1%) and hypnotic benzodiazepines >4 weeks (4.8%). In 2016, 8,743 individuals initiated at least one PIM (8.9% of the total population); 58.1% were women, mean age was 74.4 years (SD 7.6) and 73.5% used ≥10 different medications yearly. The PIM most frequently initiated were proton-pump inhibitors >8 weeks (4.2%), anticholinergic antiemetics (4.0%), first-generation antihistamines (3.4%), loperamide (3.0%), long-acting benzodiazepines (2.7%) and antitussives anticholinergics (2.1%).

Conclusions: PIM use remains common in community-dwelling older adults in France. Effective targeted-interventions should be implemented particularly to prevent PIM initiation and also to promote their deprescribing.

4032 | The epidemiology of polypharmacy in a large cohort with linked health records over 5 years of follow-up in Scotland

Mina Khezrian, Phyo Myint, Chris McNeil, Marjorie Johnston and Alison Murray

University of Aberdeen, Aberdeen, United Kingdom

Background: Most of the outcomes associated with polypharmacy, concomitant use of several drugs, are independently associated with pre-existing multimorbidity. Therefore, our understanding of the potential harm of taking multiple medications in older, multi-morbid populations is limited.

Objectives: We aimed to measure the prevalence of polypharmacy and to model the association of polypharmacy and hospitalization in a large cohort with linked health data over 5 years of follow-up.

Methods: This was a prospective observational cohort study using linked administrative data. Prescription and hospital admission records of the Aberdeen Children of the 1950s Cohort were extracted from the National Health Services Scotland database and linked from 2011-2016. We estimated polypharmacy by measuring monthly drug exposure for 1) total number of prescribed medications and 2) total number of defined daily doses (DDDs). Cox proportional hazard models (adjusted for demographics, socioeconomic circumstances and health conditions) were used to examine the association of polypharmacy and hospitalization.

Results: Prescription records were successfully linked for 8,735 participants. Mean age at baseline was 58.5 years (SD=1.5) and 50% were female. The proportion of cohort with polypharmacy (taking 5+ medications; taking 5+ DDDs) at baseline was 20.9% for counting medications (female=21.4% vs male=20.3%, P=0.179), and 21.9% for counting DDDs (female=20.6% vs male=23.1%, P=0.007). The prevalence of excessive polypharmacy (taking 10+ medications; taking 10+ DDDs) was 6.3% for counting medications (female=6.7% vs male= 6.0%, P=0.219), and 8.6% for counting DDDs (female= 7.9% vs male=9.3%, P=0.030). After adjustment for confounders, the hazard ratio for hospitalization was 1.40 (95 % CI 1.31-1.51) for polypharmacy measured by number of medications and 1.35 (95 % CI 1.26-1.45) for polypharmacy estimated by number of DDDs. Hazard ratios for excessive polypharmacy was 1.54 (95 % CI 1.38-1.71) for count of medications and 1.37 (95 % CI 1.24-1.50) for count of DDDs.

Conclusions: The prevalence of polypharmacy varies in male and female depending on the method used to estimate it in this cohort. Polypharmacy and excessive polypharmacy are independently associated with hospitalization. The extent to which polypharmacy is the proximate cause of poor outcome rather than a marker of the increased risk needs to be confirmed further. More studies are needed to generate evidence-based information for future policy and health services to improve polypharmacy measurement and management.

4052 | Anticholinergic burden and fractures in older adults: Results from a methodological systematic review

Jonas Reinold[1], Wiebke Schäfer[1], Lara Christianson[2], Francesco Barone-Adesi[3], Oliver Riedel[1] and Federica Edith Pisa[1]

[1]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany; [2]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany; [3]University of Eastern Piedmont, Novara, Italy

Background: Medications with anticholinergic activity (MACs) are used to treat many diseases common in older adults. Evidence on the association between high anticholinergic burden and increased risk of fractures is inconsistent.

Objectives: To conduct a systematic review of observational studies addressing the association of anticholinergic burden with fractures and to provide a methodological appraisal.

Methods: We searched MEDLINE, EMBASE, the Science Citation Index, CENTRAL and grey literature combining the terms "anticholinergic" and "fractures" from database inception to 2018. The eligibility criteria were: observational design (excluding cross-sectional studies), anticholinergic burden exposure measured through a scale, fracture of any type as outcome, and reported crude or adjusted measures of effect. No restrictions related to time, language or type of data were applied. The risk of bias was assessed using the Newcastle-Ottawa Quality Assessment Scale and RTI Item Bank.

Results: We included 9 studies with a total population of 610,862 persons, 74% (n=452,659) of which were women, mainly drawn from

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

North America (n=363,723; 60%) and East Asia (n=175,686; 29%). Study participants were mostly older adults aged ≥65 years (N=5 studies). The most commonly used tool to assess exposure was the Anticholinergic Risk Scale (ARS) (N=5 studies). No study used a new-user design. Only (N=3) studies included a longitudinal assessment of exposure. The most common outcome were any fractures (N=4), and hip fractures (N=3). The majority of studies had a low risk of bias. Baseline prevalence of MAC ranged from 8% to 85%; 7 studies reported an increased risk of fractures associated with anticholinergic burden. In studies using the ARS, the adjusted risk of fractures was increased by 2-61% for an ARS score of 1, by 0-97% for an ARS of 2, by 19-84% for an ARS of 3, and by 56-96% for an ARS of ≥4; in two studies the ARS was aggregated with a risk increased by 39% for ARS of 1-2 and by 17% for ARS 2-3, respectively. In the other two studies the risk was no longer increased when factors related to health status and risk factors for fractures were adjusted for.

Conclusions: This systematic review suggests that an increased risk of fractures is associated with anticholinergic burden with possible dose-exposure gradient in studies using the ARS. The low number of studies and heterogeneity of the employed methods calls for the conduct of more studies using consistent methodology.

4060 | Longitudinal trajectories of frailty in older populations: Latent curve models and mortality

Victoria Y. Strauss, Danielle E. Robinson, Antonella Delmestri, Daniel Prieto-Alhambra and Alan Silman

Botnar Research Centre, NDORMS, University of Oxford, Oxford, United Kingdom

Background: A validated frailty index (eFI) based on cumulative deficits in the electronic primary care record has been implemented in the UK NHS primary care. eFI scores categorise people into fit, mild, moderate and severely frail, whilst ignoring transitions between stages.

Objectives: To identify clusters of frailty trajectories over five years; and to examine their association with subsequent mortality.

Methods: A cohort of 270,908 older people, aged 65+ in 2009 and alive in 2013, were identified from UK primary care records (CPRD GOLD) linked to hospital inpatient and mortality data. Each calendar year, eFI index was applied to calculate the cumulative number of deficits. These deficit counts were modelled with latent class growth analyses to identify clusters of people with differential frailty trajectories. Bayesian information criterion (BIC) was used to select the optimal number of clusters and distribution. To illustrate transition between stages over five years, the emerging clusters were retro fitted to predefined frailty stages at each year. Follow up after classification in frailty trajectories went from 1/1/2014 until end of 2018, death, or loss to follow-up, and Cox models used to estimate relative risk of death according to frailty trajectory clusters, adjusted for age and gender.

Results: Overall, mean (SD) eFI changed from 0.11(0.08) to 1.48 (0.09), indicating slow worsening frailty. Five-cluster Poisson models of frailty trajectories had the smallest BIC. Two clusters (C5, 6%, C4, 20%) included fit people remaining fit with zero deficit throughout the 5-year period, and with slowly onset frailty (increasing from 0 to up to 2 deficits over the 5-year period), respectively. One cluster (C3, 37%) could be classified as slow frailty progression from pre to mild frail. Patients in C2 (29%) and C1 (8%) experienced slow accelerating rates of mild and moderate frailty respectively. Patients with slowly onset frailty cluster, C4, and slow frailty progression cluster, C3, were 24% (95% CI: 1.17, 1.31) and 53% (1.46, 1.61), respectively, more likely to die in 5 years compared to C5. The death risk increased to twice for patients in the two clusters of slow acceleration of mild (C2) and moderate (C1) frailty.

Conclusions: Five distinct frailty trajectories are identified in older patients including one cluster experiencing transitions from fit to mild frailty and over 50% higher risk of mortality. Further research is needed, including the validation of the identified clusters in external datasets.

4166 | Associations between patterns of antipsychotic use and mortality among older adults with late-life psychotic disorders

Soham Rej[1] and Dallas Seitz[2]

[1]*McGill University, Montreal, QC, Canada;* [2]*University of Calgary, Calgary, AB, Canada*

Background: Antipsychotic medications (AP) are important in management of individuals with schizophrenia and related psychotic disorders. Concerns about the safety of AP in older adults have been raised largely from studies of individuals with dementia where an increased risk of mortality has been observed. There is little know about whether there is an increased risk of death associated with the use of AP in older adults with late-life psychosis (LLP).

Objectives: 1.) To evaluate the associations between use of APs in older adults with LLP and the subsequent risk of mortality in this population.

Methods: We identified all adults aged 66 years and older who met criteria for a psychotic disorder (schizophrenia or schizoaffective disorder) in Ontario, Canada between 2008 and 2016. A validated algorithm was used to identify individuals with LLP using outpatient physician visits and hospitalization data. AP exposure was assessed in the 5 years preceding and 5 years following cohort entry. Cumulative AP doses were recorded using defined daily doses for both oral and long-acting injectable AP and AP was categorized as atypical monotherapy, typical monotherapy, AP polypharmacy, and by relative different doses of AP based on Olanzapine equivalents. Cox proportional hazards models were used to determine the associations between patterns of cumulative AP exposure and mortality.

Results: A total of 6,498 individuals were included in the study cohort. At baseline, 28% of individuals did not receive any AP in the 120 days preceding cohort entry, 42% received atypical AP monotherapy, 8% received typical AP monotherapy, and 22% received antipsychotic polypharmacy. When compared to no use of AP, there was a reduced risk of mortality in association with exposure to an atypical AP

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

monotherapy (HR: 0.60, 95% CI: 0.52 - 0.69), typical AP monotherapy (HR: 0.71, 95% CI: 0.55 - 0.93), and AP polypharmacy (HR: 0.65, 95% CI: 0.54 - 0.79). These results were consistent in subgroups with and without dementia, after adjustment for baseline differences between AP exposure groups, and in an sensitivity analysis incorporating a grace period for definition of AP discontinuation dates.

Conclusions: In this large population-based cohort study, AP use was associated with a reduced risk of mortality among older adults with LLP, even among those with comorbid dementia. Clinicians should be aware of the specific benefits and risks of AP in older adults which may be different for those with late-life psychosis when compared to other populations of older adults.

4171 | Patterns of rate control, rhythm control and anticoagulant medication use before and after nursing home admission among residents with dysrhythmias

Qiaoxi Chen, Kate Lapane and Matthew Alcusky
University of Massachusetts Medical School, Worcester, MA

Background: Management of dysrhythmias typically includes use of one or more rate control, rhythm control, and anticoagulant medications to address symptoms and reduce the risk of life-threatening cardiac and cerebrovascular events.

Objectives: To describe rate control, rhythm control, and anticoagulant medication use before and after nursing home admission among residents with dysrhythmias.

Methods: Newly admitted long-stay nursing home residents between April 1st, 2011 and September 30th, 2016 were studied using the Minimum Data Set (MDS). The prevalence of atrial fibrillation or other dysrhythmias (MDS item: I0300) was estimated at admission. Use of oral rate-control, rhythm-control, and anticoagulant medications was studied in the 3 months before and 3 months after the admission using Part D claims among those with a diagnosis of dysrhythmia and continuous Medicare fee-for-service enrollment (n=107,769). Rate-control medications were further sub-classified as non-selective beta-blocking agents (BBAs), BBAs indicated for heart failure, other cardio-selective BBAs, calcium channel blockers with cardiac effects, dihydropyridine calcium channel blockers, and cardiac glycosides. Rhythm-control medications included class I and III antiarrhythmic agents. Residents were classified as non-users, discontinuers, initiators, and continuous users of each medication class based on the presence/absence of $\geq$1 claim for a medication in the class before and after admission.

Results: Among 3.4 million newly admitted nursing home residents, 18.9% had a diagnosis of dysrhythmia. The average age of residents with dysrhythmia was 89.5 years; 14.5% had a history of stroke and 34% had heart failure. Use of rate-control (79.0% before vs. 76.9% after), rhythm-control (20.4% before vs. 21.0% after), and anticoagulant medications (44.8% before vs. 43.3% after) was largely consistent after nursing home admission. Before admission, 11.3% used none of these medications and 12.5% used none afterwards. Although 11.4% of anticoagulant users discontinued after admission, 6.6% of non-users initiated anticoagulants. Among residents with heart failure, less than half (46.9%) used BBAs indicated for heart failure after nursing home admission; 19.9% used other cardio-selective and 4.0% used non-selective beta blockers.

Conclusions: Our findings suggest the large majority of newly admitted residents with dysrhythmia continue their outpatient medication regimen in the nursing home setting.

4174 | Barriers and enablers of deprescribing preventive cardiovascular/diabetes medication health care professionals' perspective

Jamila Abou
Amsterdam UMC, Amsterdam, Netherlands

Background: Both the benefits and risks of preventive medication change over time for ageing patients. Not much is known about barriers and enablers for deintensifying preventive medication from the perspective of healthcare professionals (HCPs) in the Netherlands.

Objectives: The aim of this study was to identify barriers to and enablers of deprescribing preventive cardiovascular and diabetes medicines from the perspective of HCP and to explore the role of the pharmacist in deprescribing.

Methods: Three focus groups with in total 5 general practitioners, 8 pharmacists, 3 nurse assistants, 2 geriatricians, 2 elder care physicians were conducted in 3 cities in the Netherlands. Interviews were recorded and transcribed verbatim. Directed content analysis was performed on the basis of the Theoretical Domains Framework (TDF). Two researchers separately coded the data.

Results: Most HCPs agreed that deprescribing in this area is relevant but that barriers include poor communication between the various prescribers, insufficient reimbursement, and lack of knowledge on the subject. Some HCPs feared the deterioration of their patients' health after discontinuation their cardiovascular or diabetes medicines. All HCP stated that adequate patient communication and addressing the patients' priorities enables deprescribing. A guideline could enable the process of deprescribing such medication in elderly patients. Several HCPs stated that pharmacists could enable deprescribing by conducting medication reviews or advising about side effects and drug interactions.

Conclusions: HCPs recognize the importance of deprescribing cardiovascular and diabetes medication as a medical decision that must be well grounded. A multidisciplinary approach including the pharmacist could support deprescribing.

4185 | The association between polypharmacy and frailty in older adults

Deng-Chi Yang[1], Chien-Chou Su[2] and Yea-Huei Kao Yang[2]
[1]Institute of Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [2]Institute of

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background: Polypharmacy and frailty are well-known geriatric syndromes, and both are common in older adults. Although polypharmacy and frailty often coexist and have been researched individually and extensively, the association between polypharmacy and frailty still remains unclear.

Objectives: The objective of this study was to investigate the association between the polypharmacy and frailty in older adults.

Methods: We conducted a cross-sectional study by using the database of Taiwan Longitudinal Study on Aging (TLSA). A total of 2,468 older adults (age ≥65 years) were recruited. Polypharmacy was defined as taking≥5 kinds of medication, and frailty was defined as modified Fried criteria. The geriatric syndromes included a depressive disorder, cognitive impairment, impaired activities of daily living, impaired instrumental activities of daily living, urine incontinence, pain, fall, and polypharmacy. Other characteristics were age, gender, marital status, educational level, self-rated health, and chronic diseases. Univariate analysis and multinominal logistic regression will be performed to explore the relationship between polypharmacy and frailty.

Results: Among 2,468 older adults, there were 1,229 individuals without frailty, 1,078 individuals with pre-frailty, and 161 individuals with frailty. Univariate analysis demonstrated that age, sex, education, marriage, self-rated health, depressive disorder, impaired cognition, dependence in activities of daily living, fall, urine incontinence, pain, and polypharmacy were associated with pre-frailty and frailty. In multinominal logistic regression, there was an increased risk in association between frailty and polypharmacy, but it was not statistically significant.

Conclusions: Our results showed an increased risk in association between frailty and polypharmacy although it was not significant. Owing to the cross-sectional study design, the factor of temporal relationship between polypharmacy and frailty in the older adults was not evaluated. Further longitudinal studies are needed to confirm this relationship.

4224 | Inflammatory bowel disease medication use among community-dwelling persons with and without Alzheimer´s disease

Tuulia Heikkilä, Anna-Maija Tolppanen, Marjaana Koponen, Sirpa Hartikainen and Miia Tiihonen
University of Eastern Finland, Kuopio, Finland

Background: The incidence of inflammatory bowel disease (IBD) has been increasing in western societies and therefore the prevalence is increasing in older population. We hypothesize that more and more people with IBD will get dementia in the future.

Objectives: To determine the prevalence of IBD medications use among community-dwelling IBD persons with and without Alzheimer's disease (AD).

Methods: This study was a part of the nationwide register-based MEDALZ (MEDication use and ALZheimer's disease) study. MEDALZ-data includes all community-dwelling residents of Finland diagnosed with AD during 2005-2011 (n=70 718). For each person with AD, one age-, sex- and region of residence matched comparison person without AD were identified. Persons with AD and IBD were identified from the Special Reimbursement Register. Altogether 416 (0.6%) in the AD and 426 (0.6%) in the non-AD cohort had IBD three years before the index date (date of AD diagnosis). Data on the purchases of IBD medications were obtained from the Prescription Register. Descriptive statistics were carried out using means, standard deviations (SD) and percentages.

Results: The prevalence of IBD medications use was similar in IBD persons with and without AD at the index date. Among persons with IBD 60.3% in AD and 63.6% in non-AD cohort used at least one IBD medication at the index date. The most commonly used IBD medications were mesalazine, corticosteroids, sulfasalazine, azathioprine and methotrexate.

Conclusions: Persons with and without AD used IBD medications in the same frequency and there were no changes before and after the AD diagnosis.

4237 | "I Simply Don't Know Because I Don't Know Which Drugs I Get": A qualitative study of perspectives on deprescribing among nursing home residents and their relatives

Carina Lundby[1], Trine Graabæk[1], Jesper Ryg[1], Jens Søndergaard[2], Anton Pottegård[1] and Dorthe Susanne Nielsen[1]
[1]*Odense University Hospital, Odense C, Denmark;* [2]*University of Southern Denmark, Odense C, Denmark*

Background: Use of medication with questionable benefit is common among nursing home residents. This makes deprescribing particularly relevant. To effectively carry out deprescribing in this population, it is important to understand the perspectives of both residents and relatives.

Objectives: To explore perspectives on deprescribing among nursing home residents and their relatives.

Methods: We conducted a qualitative study using semi-structured face-to-face interviews. Participants were Danish nursing home residents, deemed cognitively able to participate by nursing home staff, and relatives pointed out by the residents themselves. Interviews were audio recorded and transcribed verbatim. Analysis was conducted using systematic text condensation.

Results: Ten nursing home residents (aged 72-96 years; six women) and nine relatives (aged 45-82 years; five women) were interviewed. Three main themes reflecting their perspectives on deprescribing were identified: 1) Wishes and attitudes towards medication, 2) Knowledge and experiences with medication, and 3) Relationship with health care professionals regarding medication.

Medication was generally perceived as a necessity by the residents; however, the majority did not know which drugs they took and why, and would not notice if their medication was changed. Most participants, including both residents and relatives, had not considered the possibility of taking less medication but were open towards

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

deprescribing if proposed by the physician. Despite this, most residents did not find their medication challenging to take, regardless of their daily number of medications. Both residents and relatives generally considered the physician or the nursing home staff as being responsible for the medication; however, they would also like to be involved in or informed about medication decisions to some degree. Lastly, they generally had faith in health care professionals despite limited contact.

Conclusions: Our study suggests that many factors may affect deprescribing in the nursing home population; however, as a starting point, the willingness of nursing home residents and their relatives to try deprescribing is considerable if supported by the physician. To facilitate more deprescribing in this population, it seems that health care professionals need to initiate more discussions about the possibility of taking less medication.

4294 | Identification of dementia diseases in health claims data - Results from the German Pharmacoepidemiological Research database

Oliver Riedel, Malte Braitmaier and Ingo Langner
Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany

Background: Dementia ranks highest among neurodegenerative diseases in the elderly, and it has been estimated that Alzheimer's disease (AD) accounts for approximately 70% of all dementia cases, followed by vascular dementia (VD) with 15%. While the epidemiology of dementia in general has been well investigated, most reported estimates relate to dementia as a group of diseases. Thus, it is unclear how single entities such as AD or VD can be reliably identified in health claims data.

Objectives: To assess the plausibility of different case definitions for detecting AD, VD and other dementia (oD) in health claims data.

Methods: Using data of the year 2016 from the German Pharmacoepidemiological Research Database (GePaRD; health claims of ~17% of the German population), insurants were categorized as having AD, VD or oD based on five algorithms: at least one inpatient/outpatient AD, VD or oD diagnosis (alg. 1); at least one inpatient diagnosis or one outpatient diagnosis by a neurologist (alg. 2) and at least one prescription of antidementives (alg. 3); at least one inpatient/outpatient AD, VD or oD diagnosis and conduct of liquor diagnostics (alg. 4) or at least one inpatient AD, VD or oD diagnosis and conduct of imaging procedures (alg. 5). For algorithms 2-5, the events had to occur within a time frame of 183 days. For each algorithm, the number of detected cases and the proportions of AD/VD/oD among these cases were calculated.

Results: Overall, 215,676 cases with dementia were identified by algorithm 1, of which 23.5% had AD, 23.2% had VD and 53.3% had oD, respectively. Similar proportions were found by algorithm 2 (N=199,033, AD=23.2%, VD=22.9%, oD=53.9%), algorithm 4 (N=3,080, AD=26.3%, VD=20.2%, oD=53.5%), and algorithm 5 (N=3,154, AD=26.1%, VD=19.9%, oD=54.0%). Algorithm 3 identified 48,741 dementia patients with higher proportions of AD (45.0%) and lower proportions of VD (12.1%).

Conclusions: None of the algorithms estimated the expected proportion of 70% of AD cases among all insurants with dementia. Prescriptions and supportive diagnostics were of limited use for the algorithms, since they were rarely carried out in our study sample. Further exploration on how to improve identification of AD in health claims data is needed.

4312 | Incidence and predictors of potentially inappropriate medication use (PIMU) in the elderly population

Ramesh Madhan, Anna George Fenn Archa, Penumarthi Krishna Sai, Johny Rosangkima, Rithika V. R and Sri Harsha Chalasani
JSS College of Pharmacy, Mysuru, India

Background: Aging is an inevitable and irreversible process. With complex medical problems and polypharmacy, elderly are at a higher risk for experiencing drug related problems in hospitals and ambulatory settings.

Objectives: The study aimed to assess the prescribing pattern of drugs, incidence and predictors of Potentially Inappropriate Medication Use (PIMU).

Methods: A prospective observational study was conducted for a period of six months. All the elderly patients admitted to Departments of General Medicine and Surgery were reviewed intensively. All those patients who met the eligibility criteria were enrolled into the study and the collected data were screened to assess the prescribing pattern of drugs. PIMU were assessed by using Beers' Criteria 2015. Bivariate analysis and subsequent Multivariate logistic regression was used to assess the predictors of PIMU.

Results: Of the 656 patients, male [359 (54.72%)] predominance was observed. 75.6% of patients had $\leq$ 3 comorbid conditions and the average length of hospital stay was 6 days. Circulatory system disorders [526 (80.18%)] was commonly observed. The total medications and doses received were 5296 and 5,866 respectively. The alimentary tract and metabolism drugs [1444 (27.26%)] were most commonly used. A total of 266 drug related problems (DRPs) were identified and the most common was drug interactions [124 (46.61%)]. Further, 216 PIMU were identified from 187 patients with a prevalence was 28.5%. Drugs of nervous system [110 (50.92%)] were most frequently implicated in PIMU. Predictors of PIMU were found to be significant for patients having 3 co-morbidities, prescription with more than 8 drugs, duration of hospital stay of 6-10 days and administration of more than 100 doses during hospital stay.

Conclusions: Incidence of PIMU was high among elderly hospitalized patients. Pharmacists can play an important role in detection and prevention of PIMU in elderly patients.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4349 | Polypharmacy as a risk factor for all-cause mortality among older people in England

Yun-Ting Huang[1], Andrew Steptoe[2], Li Wei[3] and Paola Zaninotto[1]
[1]University College London, London, United Kingdom; [2]University College London, London, United Kingdom; [3]University College London, London, United Kingdom

Background: Polypharmacy is a prevalent phenomenon in older people. Both positive and negative outcomes of polypharmacy have been reported, making the role of polypharmacy somewhat uncertain. Most previous studies have found polypharmacy is associated with increased mortality in older people, but the definition of polypharmacy varies widely. Therefore, we tested this relationship by using the most common definition of polypharmacy.

Objectives: To investigate the association between polypharmacy and all-cause mortality among older people.

Methods: Participants were from the English Longitudinal Study of Ageing (ELSA), a nationally representative sample of people aged 50 and older. In 2012/2013, 7729 people participated in the nurse visits, of these, 7727 were followed up for mortality until March 2018. Complete data were available from 6757 people. Polypharmacy was defined as taking five to nine long-term medications a day for chronic diseases or chronic symptoms, while using ten or more medications was categorised as heightened polypharmacy. The presence of illness was defined as either self-reporting conditions or taking specific medications for the condition. Cox proportional hazards model was used in this study.

Results: The age- and sex-adjusted hazard ratios of polypharmacy and heightened polypharmacy were 2.35 and 4.24, respectively, and these effects on all-cause mortality were primarily attenuated when adjusting for chronic conditions such as diabetes, coronary heart diseases, lung diseases and cancer. The effects of polypharmacy and heightened polypharmacy on mortality were further attenuated after adjusting for disability and health behaviours but remained significant. After adjusting for demographics, existing chronic diseases, disability, health behaviours, cognitive function and high-risk medications, people reporting polypharmacy (n=1357) had 1.51 times higher risk of death (95% CI 1.05, 2.19) compared with people not taking any medications (n=1924). People reporting heightened polypharmacy (n=162) also had 2.12 times higher risk of death (95% CI 1.29, 3.50), by contrast, people taking one to four drugs no longer showed a higher risk of death after adjustments.

Conclusions: People reporting polypharmacy and heightened polypharmacy had a higher risk of mortality than people who did not take any medications. The results imply the presence of polypharmacy or heightened polypharmacy could be an indicator of mortality for older people, highlighting the need to ensure the appropriateness of multiple medications.

4381 | Proton pump inhibitors following strongly anticholinergic medications: A novel prescribing cascade

Shanna C. Trenaman[1], Susan K. Bowles[2], Susan Kirkland[3] and Melissa K. Andrew[4]
[1]Dalhousie University, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada; [3]Dalhousie University, Halifax, NS, Canada; [4]Dalhousie University, Halifax, NS, Canada

Background: Anticholinergic medications are associated with gastrointestinal symptoms such as dry mouth and reflux. These symptoms may be treated with proton pump inhibitors (PPI). Use of anticholinergic medications in older adults with dementia may lead to a prescribing cascade as PPI are initiated to manage adverse drug events.

Objectives: To determine prevalence and factors associated with anticholinergic medication leading to PPI prescribing cascade in older adults with dementia.

Methods: This is a retrospective cohort study using administrative claims for Nova Scotia Seniors' Pharmacare Beneficiaries with dementia (NSSPBD). The cohort included beneficiaries who received a diagnosis of dementia according to ICD-9/10 codes from physician billings between April 1, 2008 and March 30, 2015. All NSSPBD prescription claims for medications receiving a score of 3 on the anticholinergic cognitive burden scale and PPI (ATC code A02BC) were collected from April 1, 2009 to March 30, 2015. This allowed a look-back period of 1 year prior to the period of study (April 1, 2010 to March 30, 2015) to ensure PPI did not precede the anticholinergic medication. The prescribing cascade was identified when PPI prescription followed anticholinergic medication prescription by <180 days. To test robustness of the association we reduced the interval to <90, 60 and 30 days. Multivariable logistic regression was used to identify risk factors associated with the prescribing cascade.

Results: The cohort of NSSPBD included 30,703 subjects over the period of study. 9,325 NSSPBD (30.4%) received at least one prescription for an anticholinergic medication (mean age 80.6 years). 10,657 NSSPBD (34.7%) received at least one prescription for a PPI (mean age 80.9 years). 795 cases of the prescribing cascade were identified (2.6%) where the PPI was initiated within 180 days of the anticholinergic medication. Altering the window for the prescribing cascade to 90 days reduced the number of identified cases to 569 (1.9%). At 60 days the number of cases fell to 458 (1.5%). At 30 days the number of cases fell to 313 (1.0%). Logistic regression suggested that younger age (OR -0.021; 95% CI[-0.030, -0.012]) and female sex (OR -0.49; 95% CI[-0.65, -0.32]) were significant risk factors for the prescribing cascade.

Conclusions: Prescription of anticholinergic medications leading to PPI prescription in a population of older adults with dementia represents a novel prescribing cascade. Younger age and female sex was associated with the prescribing cascade. Further investigation of this prescribing cascade in populations without dementia is warranted.

4470 | Identifying fractures in medicare claims before and after the ICD-9-CM to ICD-10-CM transition

Shahar Shmuel[1], Virginia Pate[1], Yvonne Golightly[1,2,3,4], Laura Hanson[5,6], Rebecca B. Naumann[7,2], Til Stürmer[1], Marc Pepin[8], Janine C. Bailey[8], Danijela Gnjidic[9] and Jennifer L. Lund[1]

[1]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Injury Prevention Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Division of Physical Therapy, University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Division of Geriatric Medicine & Palliative Care Program, University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]Sheps Center for Health Services Research, University of North Carolina at Chapel Hill, Chapel Hill, NC; [7]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Carrboro, NC; [8]Durham VA Geriatric Research Education and Clinical Center (GRECC), Durham, NC; [9]Sydney Pharmacy School, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia

Background: Fractures are common, severe physical complications among older adults (aged 65 years+) that often result from unintentional falls and can lead to reduced long-term mobility. Since the Centers for Medicaid and Medicare Services (CMS) transitioned from the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) to the Tenth Revision, Clinical Modification (ICD-10-CM) coding on October 1, 2015, the ICD-9-CM codes used for fracture identification need to be mapped so that trends of this adverse health outcome can be studied in the ICD-10-CM era.

Objectives: We mapped and evaluated the consistency in assessing fracture diagnosis and procedure code frequency before and after the coding transition.

Methods: We graphically compared trends in the monthly prevalence and incidence of fracture diagnoses and procedures from the end of the ICD-9-CM era (January 2013 - October 2015) to the start of the ICD-10-CM era (October 2015 - December 2016) using a 1% nationwide, random sample of US Medicare claims data. Validated ICD-9-CM diagnosis and procedure codes from the algorithm developed by Ray and colleagues were mapped using the CMS General Equivalence Mappings and a forward-backward mapping (FBM) approach. We examined each fracture site (hip, radius/ulna, humerus, rib/sternum, pelvis/sacrum/coccyx, ankle, femoral shaft, hand, tibia/fibula, skull/face, foot, clavicle/scapula, and patella) individually and also a composite outcome of all non-vertebral fracture sites.

Results: The incidence and prevalence of the fracture site diagnosis codes did not have consistent trends in the two eras. For all fracture sites (other than skull/face) and the composite outcome, both measures were lower after the coding transition. For example, hip fracture incidence in December 2013 and 2016 was 0.09% and 0.02%, respectively. Whereas for the skull/face fracture diagnoses, both prevalence and incidence were higher in the ICD-10-CM era (i.e., incidence was 0.04% and 0.08% in December 2013 and 2016, respectively). The incidence and prevalence of the fracture procedure codes across eras were consistent for the humerus, skull/face, and tibia/fibula, but inconsistent for all other sites.

Conclusions: The automated mapping performance was poor for most fracture sites. Careful, manual review is needed to ensure that the relevant codes are captured after mapping.

4516 | Opioid prescribing among medicare part D providers before and after the introduction of national prescribing guidelines in the United States

Mary C. Figgatt, Kristin Y. Shiue and Yvonne M. Golightly

University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC

Background: Opioid therapy is a common pain management strategy in the United States, but prescription opioids are involved in over one-third of all opioid overdose deaths. To date, there is limited evidence of the impact of the 2016 *CDC Guideline for Prescribing Opioids for Chronic Pain* on national prescribing patterns, especially among older adults, This patient group is of particular interest because of a recent increase in opioid overdose rates among older adults and the link of opioid use with an increased risk of falls.

Objectives: To describe temporal trends in opioid prescribing among Medicare Part D providers, overall, by prescriber specialty, and by state.

Methods: Descriptive analyses were conducted using data from the Medicare Part D Prescriber Public Use Files for 2015-2017 (n=1300319 unique providers). Opioid prescribers, defined as providers with >10 claims for any opioids, were evaluated as a percent of all Part D providers. Mean days supply was calculated as the sum of all days supply divided by the total count of opioid claims.

Results: From 2015-2017, the percent of Part D providers prescribing opioids declined from 74% to 71%, representing a decrease of over 4 million claims per year. Nearly all providers (>95%) in pain management, maxillofacial surgery, orthopedic surgery, rheumatology, and emergency medicine were opioid prescribers, though there was a slight decline observed in rheumatologists (2015: 97%, 2017: 94%). The most commonly represented specialties were internal medicine (13%), dentistry (13%), family medicine (12%), emergency medicine (6%), and obstetrics/gynecology (3%). Within these top specialties, the reduction in opioid prescribing was the greatest in obstetrics/gynecology (-5%) and dentistry (-4%), while across all specialties, the greatest absolute decline occurred in cardiology (-12%). By state[GY1] [SKY2], opioid prescribing decreased most notably in the Northeast (-7% to -4%), including New Hampshire, Massachusetts, New York, Maine, Pennsylvania, New Jersey, Vermont, and Connecticut. There were no meaningful changes in mean days supply from 2015-2017 (22 days per claim).

Conclusions: Although we observed slight decreases in the proportion of providers prescribing opioids, the overall mean days supply remained relatively constant[GY1] despite recommendations for

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

clinicians to limit prescriptions for acute pain to ≤7 days. Further research should examine provider prescribing behaviors in relation to existing guidelines, in addition to opioid prescribing trends among populations not served by Medicare Part D.

4557 | Impact of polypharmacy on risk of mortality among older people who received home care: A retrospective longitudinal cohort study

Shih-Tsung Huang[1], Liang-Kung Chen[2] and Fei-Yuan Hsiao[1]
[1]*College of Medicine, National Taiwan University, Taipei, Taiwan;*
[2]*National Yang-Ming University School of Medicine, Taipei, Taiwan*

Background: Older people who need home care are usually characterized by very old age, severe disability, multimorbidity as well as polypharmacy. Although polypharmacy has been identified as one of the modifiable factors to these people, conflicting data has been reported to the association between polypharmacy and clinical adverse events. These discrepancies in previous studies may result from different methodological limitations of existing studies, including small sample size or one-time measurement of polypharmacy status.
Objectives: This study aims to examine the association between polypharmacy and the risk of mortality in older people who need home care by adopting the time-varying (quarterly) measures of polypharmacy status.
Methods: People aged 65 years or older who were newly received home care service between 2008 to 2010 were identified from Taiwan's National Health Insurance Research Database. To prevent protopathic bias and guarantee that the identified participants' prescription records can be fully assessed for the first quarter, patients who died in the first quarter have been excluded. Polypharmacy status were collected on a quarterly basis during the 5 years follow-up period. The chronic use of 0 to 4 medications was consider as non-polypharmacy, 5 to 9 medications as polypharmacy, and 10 medications or more as excessive polypharmacy. All deaths occurring during the 5-year follow up period were identified. Generalized estimating equation model was used to examine the association between distinct polypharmacy status and risk of 1-, 3- and 5-years mortality.
Results: The mean age of 50,210 eligible subjects were 80.5 years, with 52.3% of women, and 78.9% of them have the Charlson's comorbidity index (CCI) scored to 2 and above. The mean follow-up period was 31.2 months. We categorized our study subjects into non-polypharmacy (n=14,198, 28.3%), polypharmacy (n=25,489, 50.8%) and excessive polypharmacy group (n=10,523, 21.0%) according their first quarter of polypharmacy status. After adjustment for age, sex, CCI, and other comorbidities, the GEE models indicated that polypharmacy and excessive polypharmacy group had lower risk of 5-year all-cause mortality than non-polypharmacy group (polypharmacy: adjusted odds ratio [aOR] =0.76, 95% CI=0.74-0.78; excessive polypharmacy: aOR=0.73, 95% CI=0.71-0.76). Similar results were observed at 1- and 3- years of follow-up.
Conclusions: Polypharmacy did not appear to significantly increase the risk of short- and long-tern mortality among home care patients, which deserves further prospective study to clarify.

4589 | Antipsychotics and mortality risk in patients with dementia and comorbidities

Ane Nørgaard Christensen[1], Theresa Wimberley[2], Thomas M. Laursen[3], Kazi Isthiak Ahmed[4,5], Jesper Hastrup Svendsen[6], Christina El-Ali Jensen-Dahm[1], Gunhild Waldemar[1] and Christiane Gasse[4]
[1]*Rigshospitalet, University of Copenhagen, Copenhagen, Denmark;*
[2]*Aarhus University, Aarhus, Denmark;* [3]*Aarhus University, Aarhus, Denmark;* [4]*Aarhus University Hospital Psychiatry, Aarhus University, Aarhus, Denmark;* [5]*University of Copenhagen, Copenhagen, Denmark;*
[6]*Rigshospitalet, University of Copenhagen, Copenhagen, Denmark*

Background: Antipsychotic drugs are commonly used to treat behavioral and psychological symptoms in patients with dementia. Antipsychotics are associated with increased risks of adverse events and death, which may vary in patients with comorbid conditions.
Objectives: To investigate whether cardiovascular and metabolic comorbidities affect the mortality risk associated with the initiation of antipsychotic treatment in patients with dementia.
Methods: We conducted a population-based matched cohort study using nationwide Danish registry data. The study population included all residents aged 65-95 with dementia in 2009-2014. Dementia was identified at a first-time dementia diagnosis registered in the Danish Hospital Registers and/or a first-time prescription for anti-dementia medication. Patients exposed to antipsychotics after dementia diagnosis were matched with up to three unexposed patients on sex, and age at and calendar year of the first-time dementia diagnosis. Patients were followed from the date of the first prescription for an antipsychotic (index date) until death, emigration, or Dec 31, 2015, whichever came first. We estimated hazard ratios (HR) with 95% confidence intervals (CI) using Cox proportional hazards analyses comparing mortality rates within 180 days after the index date in antipsychotic users and non-users. We adjusted for potential confounders, including living status, Charlson Comorbidity Index, psychiatric comorbidity, antidepressant or benzodiazepine use, tested for interactions, and stratified the analyses by diabetes, heart disease, and cerebrovascular disease.
Results: The study cohort included 8,244 exposed patients and 24,730 unexposed patients who were followed for 14,285.6 person-years (PYs). During the first 180 days of follow-up, 5,938 patients died (41.6/100 PYs). Patients exposed to antipsychotics had a crude mortality rate of 56/100 PYs, and a significantly higher risk of death (adjusted HR: 1.35, 95% CI: 1.27-1.43) than unexposed patients. Patients with heart disease and diabetes had overall higher mortality rates/100 PYs compared with patients without, particularly when using antipsychotics (heart disease: 78.2/100PYs (72.9-83.9), diabetes 69.5/100 PYs (62.7-77.0)). HRs within strata were not statistically different from the overall adjusted HRs.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusions: This study adds to the evidence that antipsychotic treatment is associated with an increased mortality. Caution in prescribing antipsychotics should be taken for all patients but most importantly for patients with prior comorbid disease related to the cardiovascular and metabolic systems.

4607 | Incident antiepileptic use and risk of hip fracture among persons with Alzheimer's disease

Federica Pisa[1,2,3], Jonas Reinold[4,2], Piia Lavikainen[5], Marjaana Koponen[5,6], Heidi Taipale[5,7,8], Antti Tanskanen[7,8,9], Jari Tiihonen[7,8,10], Sirpa Hartikainen[5] and Anna-Maija Tolppanen[2]

[1]UCB Pharma, Brussels, Belgium; [2]University of Eastern Finland, Kuopio, Finland; [3]Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Germany; [4]Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Germany; [5]University of Eastern Finland, Kuopio, Finland; [6]Monash University, Melbourne, Australia; [7]Karolinska Institutet, Stockholm, Sweden; [8]Niuvanniemi Hospital, University of Eastern Finland, Kuopio, Finland; [9]National Institute for Health and Welfare, Helsinki, Finland; [10]Center for Psychiatry Research, Stockholm City Council, Stockholm, Sweden

Background: Antiepileptic drugs (AEDs) have been associated with increased risk of hip fractures in adults with epilepsy, but the evidence for older adults with Alzheimer´s disease (AD) is limited.

Objectives: We conducted a matched cohort study to determine the risk of hip fracture in persons with AD who initiated AEDs.

Methods: In the Medication use and AD (MEDALZ) cohort of 70,718 Finnish community dwellers with clinically verified AD diagnosis in 2005-2011, we identified all incident users of AEDs using national Prescription register. Incident users were persons with a first AED dispensation after AD diagnosis without any AED use within 1 year before. AEDs were classified as older (valproate, carbamazepine, clonazepam, phenytoin, levetiracetam, primidone) or newer (pregabalin, gabapentin, oxcarbazepine, lamotrigine, topiramate). We matched each user to 2 non-users by sex, age (±1 year), and time since AD diagnosis (± 183 days) using incidence density sampling without replacement. Incident hip fractures until 2015 were identified from Care register for health care. We calculated age- and sex- adjusted incidence rates (aIRs) of hip fracture and inverse probability of treatment weighted hazard ratio (IPTW HR), using Cox regression.

Results: 5,522 incident users were identified and matched to 11,044 non-users (in both groups, women: 65%; median age: 81 years). 53.3% of users initiated with newer AEDs (pregabalin 79.8%, gabapentin 10.2%) while 46.7% initiated with older AEDs (valproate 67.6%, carbamazepine 13.0%). aIR of hip fracture (/100 person-years) was 1.6 (95% CI 1.5-1.8) in non-users and 1.9 (1.7-2.2) in users. IPTW HR was 1.17 (1.05-1.30) in users compared with non-users; it was 1.28 (1.10-1.49) for short (<14 weeks) and 1.42 (1.22-1.66) for medium (14 to <64 weeks) duration of use, compared with duration ≥64 weeks. Older AEDs had HR of 0.96 (0.77-1.19) compared with newer AEDs.

Conclusions: Higher risk of hip fracture in AED users prompts careful consideration before prescribing AEDs to persons with AD and monitoring of those who need to be treated.

4678 | Network analysis of interacting medication use in elderly persons in Norway

Mohsen Askar and Kristian Svendsen

UiT - The Arctic University of Norway, Tromso, Norway

Background: Co-use of medications is common amongst patients and especially elderly who have more morbidities. This use is often beneficial but it also carries increased risks of drug-drug interactions (DDI) and adverse drug reactions

Objectives: Using network analysis to map and study the comedication of interacting medications in the elderly Norwegian population.

Methods: We used data from the Norwegian Prescription Database (NorPD) from 2012-2014 of dispensed medications among persons 65 years or older. The total population was 765,383 persons with over 62 million prescriptions. Of these our study population consisted of 669,683 persons having at least one prescription dispensed covering the index date of 1.1.2013. The covered days was calculated for each prescription using number of Defined Daily Doses dispensed. Treatment episodes were constructed using Proportion of Days Covered (PDC) and allowing for 80% adherence and a 14 days gap period. Any treatment episodes covering the index date was included and used to create co-medication patterns. Drug-drug interactions (DDI) were found using the National Prescription support database (FEST) from the Norwegian Medicines Agency. Only severe interactions that should be fully avoided was used in this study. This consisted of 57,151 severe interactions in 1699 different drugs. Prescription data from the NorPD was merged with DDI data from FEST using ATC codes and visualized as a network using Gephi 0.9.2

Results: Combining the interaction data with drug utilisation data provided 229 drugs with 662 interactions used by the study population. The data has been visualised as a network to see the pattern of use. Simvastatin in combination with atorvastatin was the most commonly co-used interacting medications with 2320 users representing 0.35% of elderly medication users. Other interesting interactions within the top 10 most used DDI combinations are esomeprazole and clopidogrel, simvastatin and carbamazepine, metoprolol and paroxetine (pharmacokinetic) and metoprolol and verapamil (pharmacodynamic). All of these with a prevalence of between 0.12 and 0.06% of the study population. The network showing all interactions where the medications included has at least 900 (0.13%) users can be seen online here: https://www.dropbox.com/s/8rv782gdh48ro5t

Conclusions: There are many severe interactions occurring in the elderly Norwegian population. None of them are very common, but our results will allow for further research into the use of medications with severe interactions and could be used in research into the role DDIs have in outcomes such as hospital admissions and death.

4718 | The association between medication and alcohol use and the incidence of frailty among older adults: An international retrospective cohort study

Janja Jazbar, Igor Locatelli and Mitja Kos
University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia

Background: Frailty as an age related syndrome is considered one of the most pressing public health challenges as the population is aging worldwide. Understanding potentially modifiable factors that influence the risk of frailty is one of the key concerns in managing frailty.
Objectives: To evaluate the association between medication and alcohol use and the incidence of frailty among older adults.
Methods: This study was a retrospective cohort study on older adult outpatients (≥ 65 years) using the data from the longitudinal Survey of Health, Ageing and Retirement in Europe (SHARE survey, 27 European countries). Data from 2013 (wave 5) and 2015 (wave 6) were used for the analysis. The exposures were medication and alcohol use measured at baseline (in 2013). Medication use was measured as number of concomitant medication classes. Exposure to alcohol was assessed with two variables, namely alcohol use (AUDIT-C) and excessive drinking problems in the past. The outcome measure was the incidence of frailty after two years (in 2015), defined by frailty index. Multiple logistic regression model was used to evaluate the association with adjustment for several potential confounding factors.
Results: Of the 17,489 nonfrail participants at baseline, 2,104 (12.0%) developed frailty syndrome in two years. Participants with more medication classes at baseline had higher incidence of frailty (4.6% in the population without chronic medication compared to 30.7% in the population with 5 or more medication classes). The adjusted odds ratios (95% CI) for the incidence of frailty when taking 1-2, 3-4 and ≥5 concomitant medication classes compared to no medications were 1.74 (1.44-2.09), 2.89 (2.34-3.57), and 4.67 (3.51-6.21), respectively. The adjusted odds ratios (95% CI) of frailty in non-hazardous and hazardous alcohol users compared to no alcohol users were 0.67 (0.59-0.75) and 0.78 (0.67-0.90), respectively. Participants with excessive drinking problem in the past had higher odds ratio for frailty compared to participants with no drinking problem in the past (adjusted OR, 95% CI: 2.20, 1.62-2.99; incidence: 16.4% vs. 10.1%).
Conclusions: The use of higher number of concomitant medication classes is associated with higher incidence of frailty. Hazardous and non-hazardous alcohol use are associated with decreased incidence of frailty compared to no alcohol use, which may be due to reversed causality. Excessive drinking problem in the past is associated with increased incidence of frailty, which supports the literature on harmful effects of alcohol use on frailty syndrome.

4735 | Discharge prescribing in older adults with type 2 diabetes hospitalised for diabetes-related complications

Stephen Wood[1], J. Simon Bell[1,2], Dianna Magliano[3,2] and Jenni Ilomäki[4,2]
[1]Monash University, Melbourne, Australia; [2]Monash University, Melbourne, Australia; [3]Baker Heart and Diabetes Institute, Melbourne, Australia; [4]Monash University, Parkville, Australia

Background: Intensive therapy is often required for the treatment of Type 2 Diabetes (T2D) in order to achieve glycated haemoglobin (HbA_{1C}) targets as the disease progresses. However, this must be balanced against the need to avoid aggressive treatment in vulnerable populations such as older or frail individuals and those with dementia, since stringent glycated haemoglobin targets confer no known benefits to these people.
Objectives: To determine whether age, frailty or dementia are associated with the intensity of anti-hyperglycaemic therapies prescribed for hospitalised patients at discharge.
Methods: A cross-sectional study was completed using discharge prescribing data from Melbourne's Eastern Health (EH) hospital network. We identified 3,067 patients aged 65-99 years with T2D, at least one diabetes related complication and an index discharge between 2012 and 2016. Multinomial Logistic Regression was used to estimate Odds Ratios (ORs) with 95% confidence intervals (CI) for being prescribed insulin, non-insulin anti-hyperglycaemics or a combination of those two compared to no anti-hyperglycaemics. T2D, relevant co-morbidities, diabetes complications, level of frailty and number of co-morbidities, indicated by the Charlson Comorbidities Index (CCI), were identified using International Classification of Diseases-10 (ICD-10) codes. Medications were identified Anatomical Therapeutic Chemical (ATC) codes: insulins (A10A) and non-insulin anti-hyperglycaemics (A10B).
Results: No T2D therapy, insulin, non-insulin T2D therapy, and combinations of insulin and non-insulin therapy respectively, made up 23%, 19%, 39%, 20% of the cohort. People aged >80 were less likely than people aged 65-80 to be discharged with insulin (OR 0.53; 95%CI [0.42-0.68]), non-insulin T2D therapy (OR 0.67; 95%CI [0.55-0.81]), or combinations of these two (OR 0.37; 95%CI [0.30-0.47]), compared to no T2D therapy. Frailty was associated with lower odds of being prescribed insulin (OR 0.64; 95%CI [0.43-0.94]) or non-insulin T2D therapy (OR 0.64; 95% CI [0.46-0.89]), compared to no T2D therapy. People with dementia were less likely to be discharged with insulin and non-insulin combinations (OR 0.56; 95%CI [0.34-0.92]) compared to no T2D medication.
Conclusions: Prescribers are aware that people >80 years and frail individuals require less aggressive treatment targets in T2D compared to older people aged 65-80 years and those who are not frail. People with dementia are also less likely to be prescribed combinations of insulin and non-insulin anti-hyperglycaemics compared to those without dementia.

4749 | Prescription gabapentinoid use and opioid-related adverse events in medicare older adults

Cheng Chen, Almut G. Winterstein, Wei-Hsuan Jenny Lo-Ciganic, Patrick J. Tighe and Yu-Jung Jenny Wei
University of Florida, Gainesville, FL

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Use of prescription gabapentinoids (i.e., gabapentin and pregabalin) in older adults has increased 3-fold from 2002 to 2015. Gabapentinoid use is suspected as a contributor to the rising rates of hospitalizations due to opioid use disorder (OUD) and overdose in this population.

Objectives: To examine the association between gabapentinoid use and opioid-related adverse events among older adults.

Methods: In a case-crossover study using 5% Medicare claims data (2011-2015), we included fee-for-service beneficiaries aged ≥65 years newly diagnosed with an opioid-related adverse event (i.e., OUD or overdose) in the inpatient or outpatient settings. New cases were defined as having no diagnosis of opioid-related adverse events during the 180 days before the first OUD or overdose event (i.e., index event). We excluded beneficiaries who were not continuously enrolled, did not use prescription opioids, had a cancer diagnosis, or used hospice or palliative care services in the 180-day pre-index period. Within each patient, we compared the exposure to gabapentinoids during a 30-day hazard period (i.e., the 1-30 days before the index event) with the exposure during two 30-day control periods (i.e., the 61-90 and 121-150 days before the index event). Conditional logistic regression models were used to estimate the odds ratios (ORs) and 95% confidence intervals (CIs) of gabapentinoid exposure, adjusting for concurrent prescription opioid use and dose and other medication use. To address temporal trends in pain management, we conducted a case-time-control analysis by estimating the OR of gabapentinoid use in a control group without opioid-related adverse events. A trend-adjusted OR was calculated as the ratio of ORs in the cases and controls.

Results: We identified 11,481 older adults newly diagnosed with an opioid-related adverse event (mean age=74±7; female=70%; White=86%). The prevalence of gabapentinoid use during the hazard period (30%) was slightly higher than in the two control periods (28% and 26%). The main analysis showed a positive association between gabapentinoid use and opioid-related adverse events (OR=1.62, 95% CI=1.46-1.80). Case-time-control analysis yielded similar results (trend-adjusted OR=1.37, 95% CI=1.08-1.74). We observed associations in both gabapentin-only (OR=1.69, 95% CI=1.50-1.90) and pregabalin-only users (OR=1.31, 95% CI=1.01-1.70).

Conclusions: Medicare older adults who had an opioid-related adverse event were more likely to have prescription gabapentinoid in the immediate 30 days before the event than in more distant historical control periods.

5043 | The use of preventative treatments (statins, bisphosphates and anti-hypertensives) in older patients with complex health needs: An analysis of UK primary care and linked hospital data

Ying He, Leena Elhussein, Antonella Delmestri, Danielle Robinson, Victoria Y Strauss and Daniel Prieto-Alhambra

Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Background: With an increasing ageing population, the UK NHS is under pressure to provide large amounts of long-term treatments for the prevention of cardiovascular disease and fragility fractures.

Objectives: We aim to characterise the population-level use of key preventative therapies (statins, bisphosphonates and anti-hypertensives) in three cohorts of older patients with complex health needs based on healthcare resource use, frailty (electronic frailty index (eFI) score) and polypharmacy respectively.

Methods: All participants aged 65 or older on 1 Jan 2009, registered to an up-to-standard practice for at least 1 year were identified from a UK primary care database (CPRD GOLD) and linked to Hospital Episode Statistics (HES) and The Office for National Statistics mortality register. Patients were followed up until the earliest of practice last collection date, patient transfer-out date, death date or data download date. Three cohorts were identified based on the top quintile of 1) number of unplanned hospital admissions in HES (cohort1), 2) eFI score (cohort2), and 3) number of different medications prescribed (cohort3), in the previous year. We estimated the point prevalence (PP) at study start date. Incident use was defined as new use after start date without use in the month prior to or on this date. Incidence rates (IR) of each drug group was calculated using Poisson regression model.

Results: A total of 73,724, 100,485 and 100,965 participants were identified in cohorts 1-3 respectively. The PP at start date for statins was 31.7%, 38.7% and 43.6%; for bisphosphates 7.0%, 7.3% and 9.8%; and for anti-hypertensives 50.1%, 59.8% and 66.1% in cohorts 1-3, respectively. The average follow-up time for the three cohort patients was 4.99, 5.06 and 5.18 years respectively. The overall IRs for statins in cohorts 1-3 were 5.31 (95%CI 5.23, 5.38), 5.29 (95%CI 5.23, 5.35) and 5.24 (95%CI 5.18, 5.30) per 100 person-years, respectively. The IRs were lower for bisphosphonates: 2.77 (95%CI 2.71, 2.82), 2.71 (95%CI 2.67, 2.76) and 2.98 (95%CI 2.94, 3.03) in cohorts 1-3 respectively; whereas the IRs of anti-hypertensives were slightly higher or similar compared to the IRs of statins: 6.11 (95%CI 6.03, 6.19), 5.60 (95%CI 5.53, 5.66) and 5.07 (95%CI 5.01, 5.13) in cohorts 1-3.

Conclusions: Statins, bisphosphonates, and anti-hypertensives are commonly prescribed among older patients with complex health needs. Further research is needed on the effectiveness and safety of preventative medications for these patients.

5113 | Predicting fall risks in older adults with atrial fibrillation

Kueiyu Joshua Lin[1,2], Ajinkya Pawar[1], Nileesa Gautam[1] and Dae Hyun Kim[1,3]

[1]*Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA;* [2]*Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA;* [3]*Hebrew Rehabilitation Center, Harvard Medical School, Boston, MA*

Background: High risk of falling is one of the leading reasons for withholding anticoagulation in patients with Atrial fibrillation (AF) when it

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

is recommended by clinical guidelines. However, such risk is often assessed arbitrarily and there is no objective fall assessment developed for this particular population.

Objectives: To externally test the performance of a claims-based fall risk prediction score developed by Homer et al. in the general population and optimize it in older adults taking oral anticoagulant (OAC) for non-valvular AF by incorporating additional relevant predictors.

Methods: We used the US Medicare claims data to identify new initiators aged ≥ 65 years of OAC (warfarin, dabigatran, rivaroxaban, or apixaban) with a diagnosis for non-valvular AF in the preceding 180 days from 2010/10 to 2014/12. We held out patients from the Midwestern US as the validation set and used patients from all other US regions as the training set for the model development. We used Lasso regression with 5-fold cross-validation to select among the component variables in the previously developed 39-variable Homer score (Am J Med 2017) and 174 additional predictors based on literature, predicting 1-year risk of fall requiring hospitalization. We compared Homer score vs. new AF fall risk score in terms of Area under ROC curve (AUC) and reclassification, which measures performance of different scores in classifying patients into multiple risk groups. We defined the risk category as low (less than the average risk), intermediate (1 to <2 times average risk), or high (≥2 times average risk).

Results: Our study cohort included a total of 154,158 (mean age 76.4 years and female 52.8 %) patients (107,924 in training and 46,234 in validation set). Based on 3,332 fall events (3.1%) in the training set, the new AF fall risk score included 19 variables and has an AUC of 0.67 in the training and 0.67 in the validation set (superior to the corresponding Homer's AUC of 0.63 and 0.64, respectively, $p>0.001$). In the validation set, stratifying patients based on the predicted risk of our AF fall risk score, the actual fall risk in patients in the top decile was 8.2 times that in the lowest decile (6.3 vs. 0.8 %). In the validation set, our AF fall risk score reclassified 22.3, 35.8, and 48.6% of low, intermediate, and high-risk patients determined by Homer score with a net reclassification improvement of 5.4% ($P<0.001$).

Conclusions: When comparing effects of oral anticoagulants in patients with non-valvular AF, our claims-based AF fall risk score can be helpful in both clinical (to aid prescribing decisions) and research (to stratify patients for treatment effect heterogeneity assessment) contexts.

5139 | Impact of central nervous system depressant burden on the relationship between new opioid use and fracture risk

Qi Guan[1], David Juurlink[1], Siyu Men[2], Susan Bronskill[2], Hannah Wunsch[1], Pat Messner[3], Marie McMillan[3] and Tara Gomes[1]
[1]*University of Toronto, Toronto, ON, Canada;* [2]*ICES, Toronto, ON, Canada;* [3]*Ontario Drug Policy Research Network, Toronto, ON, Canada*

Background: Central nervous system (CNS) depressants are known to increase the risk of falling. This is particularly dangerous for older adults because falls are a leading cause of injury-related hospitalization and death in this population. However, CNS polypharmacy remains common due to the high prevalence of comorbidities in older adults.

Objectives: This study aims to assess whether additional CNS depressant burden modifies the relationship between new opioid therapy and the risk of falls/fractures.

Methods: Using administrative data from ICES, Canada, we are conducting a cohort study on adults >65 years old who started prescription analgesic therapy (opioid or non-steroidal anti-inflammatory drug [NSAID]) from 2008-2018. Individuals are stratified based on CNS depressant burden (none, low, high), measured by the number of concurrent non-opioid CNS depressant drug classes used (0, 1-2, ≥3). Within each group, opioid and NSAID users are balanced using inverse probability treatment weighting and compared using marginal Cox models to determine risk of wrist/hip fractures in the 14 days following opioid/NSAID therapy. Pairwise comparisons of outcome risk between burden groups are conducted using z-tests.

Results: Of the 1,048,330 individuals included in our study, 884,341 (84.4%) had no CNS depressant burden, 157,441 (15.0%) had low burden, and 6,528 (0.6%) had high burden. Opioid and NSAID use was almost evenly split among those with no CNS burden (N=474,813 [53.7%] for opioids and N=409,528 [46.3%] for NSAIDs) while almost 2/3 of the low and high CNS depressant burden groups consisted of opioid users (N=95,926; 60.9% and N=4,079; 62.5%, respectively). Groups experiencing more CNS depressant burden tended to have more females (range: 65.4%-67.5%) and reside in lower income neighbourhoods. While event rates were low, opioid users experienced fractures more than NSAID users (N=449, 0.09% vs N=140, 0.03% for no burden; N=166, 0.17% vs N=41, 0.07% for low burden; high burden values censored).

Conclusions: Based on crude values, opioids had more effect on falling than NSAIDs when individuals were free of CNS depressant burden. This may be attributed to lack of tolerance to CNS depressants or increased mobility due to fewer comorbidities but will be explored further with statistical modelling.

Health Economics/Outcomes Research

60 | Trial participants vs real-world users of medicines: How different are they really and does it matter?

Anton Pottegård[1], Olaf Klungel[2], Daniel Morales[3], Mehdi Najafzadeh[4]
[1]*University of Southern Denmark, Odense, Denmark;* [2]*Utrecth University, Utrecth, Denmark;* [3]*University of Dundee, Dundee, United Kingdom;* [4]*Harvard University, Boston, MA*

Background: Differences between trial participants and real-world users of medicines are often considered one of the main reasons for generating 'real-world evidence'. However, few studies have systematically explored these potential differences and their impact on study results.

Objectives: This symposium will address the following issues:

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(i) Does current evidence suggest a systematic difference between trial participants and real-world users?
(ii) To what extent are real-world users different from trial participants when considering patient characteristics and trial eligibility?
(iii) How do differences between real-world users and trial participants affect estimates of treatment effectiveness and safety?
(iv) How do differences in measurement of risk factors and outcomes affect perceived differences between trial evidence and real-world evidence?
The symposium will target any pharmacoepidemiologist working within the 'real-world evidence' space.

Description: The symposium will be initiated by prof. Anton Pottegård. The common perception that the difference between trial participants and real-world users is a well-documented fact will be challenged, followed by selected examples of real-world efficacy estimates (compared to trial findings) to set the scene for the subsequent presentations.
Prof. Olaf Klungel will review the extent of exclusion of elderly from pivotal trials on therapeutic indications typically present among elderly. Further, examples of the impact of differences in patient characteristics between trial participants and real-world users on effectiveness and safety of medicines (direct oral anticoagulants for atrial fibrillation and chemotherapy for non-small cell lung cancer) will be discussed. Daniel Morales, will review how exclusion rates vary by trial setting, funding source and over time. Examples demonstrating how differences between trial participants and real-world users impact how we quantify the safety and effectiveness of medicines (ACE inhibitors for renal disease and antiplatelets for stroke) will be discussed. Mehdi Najafzadeh, will review the difference in how outcomes and risk factors are captured in trials versus in databases. He will discuss how this impact on findings from different studies and propose potential solutions for addressing such differences in the future. The symposium will end with a panel discussion. Selected literature references will be prepared in advance for participants to easily access them.

100 | Readmissions and postoperative mortality of coronary artery revascularization in people with and without Alzheimer's disease: A nationwide cohort study

Mai Vu[1,2], Marjaana Koponen[1,3,2], Heidi Taipale[1,4,5,2], Raimo Kettunen[6], Sirpa Hartikainen[1,2] and Anna-Maija Tolppanen[1,2]
[1]University of Eastern Finland, Kuopio, Finland; [2]University of Eastern Finland, Kuopio, Finland; [3]Monash University, Parkville, Australia; [4]Karolinska Institutet, Stockholm, Sweden; [5]Niuvanniemi Hospital, Kuopio, Finland; [6]University of Eastern Finland, Kuopio, Finland

Background: Coronary artery disease is common in older persons, and one of the management strategies is revascularization procedure (coronary artery bypass grafting and percutaneous coronary intervention). However, effectiveness as well as survival rate in persons with Alzheimer's disease (AD) after these procedures have not been investigated before.

Objectives: To compare the incidence of coronary artery revascularization, readmission, and mortality after procedure among persons with and without AD.

Methods: Our study is based on a retrospective register-based Medication Use and Alzheimer's disease (MEDALZ) cohort which includes all community dwellers with a clinically verified AD diagnosis during 2005 - 2011 in Finland (N=70 719). For each incident revascularized persons with AD, four comparison persons without AD were was matched by age, sex, and hospital district. The follow-up for this study began on the date of AD diagnosis (matching date for comparison persons). Altogether 448 persons with AD and 5999 without AD underwent revascularization during the follow-up. The outcomes were 30-day and 90-day re-admission rate after discharge, and all-cause 1-year and 3-year mortality. Analyses were conducted with Cox proportional hazard models adjusted with age, sex, comorbidities, and statin use.

Results: Revascularization were less often performed in persons with AD (adjusted hazard ratio HR = 0.23, 95% CI 0.21 - 0.26). Persons with AD tended to have lower risk of 30-day readmission (adjusted HR: 0.77, 95% CI 0.57 - 1.03), and 90-days readmissions (adjusted HR: 0.87, 95% CI 0.70 - 1.08). Higher proportion of persons with AD (7.4%) died in the operative unit compared with persons without AD (4.8%) There was no difference in 1-year mortality (adjusted HR:1.20, 95%CI 0.89 - 1.62) but people with AD had higher 3-year mortality (adjusted HR: 1.73, 95%CI 1.48 - 2.01).

Conclusions: The higher three-year mortality in people with AD after revascularization is in line with the overall increase in risk of death in persons with AD. Persons with AD had higher in-hospital mortality but there were no differences in the short-term outcomes regarding rehospitalizations or death. Lower rate of revascularization, especially given the higher prevalence of ischaemic heart disease in people with AD raises questions about possible undertreatment as this group also needs these operations to improve functioning and quality of life.

2457 | Drug use variability by community sampling place and setting for rural women

Carl Leukefeld, Megan Dickson, Christopher J. McLouth, Matt Webster and Michele Staton
University of Kentucky, Lexington, KY

Background: Rural drug use across the US has increased, as has the number of studies examining those increases. However, there is a paucity of studies focused specifically on rural women.

Objectives: This study examines self-reported drug use in two rural county settings among women on public assistance (Welfare to Work) and in community confinement (jails) to: 1) determine how drug use

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patterns compare across sampling place, and 2) describe how county setting relates to self-reported drug use. It was hypothesized that rural women in jails would report more drug-involvement than those in Welfare to Work settings, but that there would also be differences related to county of recruitment.

Methods: The current study design includes data from two datasets of drug-using rural women who were consented during the same time period (between December 2012 and August 2015), in the same two rural Appalachian Kentucky counties. The first dataset includes random selection and interviews with 279 women recruited from two county jails. The second dataset is 254 low-income women on Welfare to Work (public assistance). The current study includes baseline measures from both datasets such as self-reported lifetime drug use from the Addiction Severity Index. Participation rates exceeded 80% in the both samples. Logistic regressions controlling for demographic differences and county were used to compare drug use patterns across samples.

Results: Women recruited from jail were significantly older ($p<.001$), more likely to be white ($p=.022$), married ($p=.010$), and have less than a high school education ($p=.011$). When controlling for recruitment county and demographic differences, women recruited from jail were more likely to self-report having used of 8 of the 9 drugs examined, as well as injecting (AOR=12.66; $p<.001$) and multiple drug use (AOR=14.31; $p<.001$). Examining individual samples across county sites found similarities in drug use patterns by county of recruitment. Specifically the prevalence of methamphetamine use was significantly higher ($p<.001$) in both samples from the same site, while illicit methadone use was significantly lower ($p<.05$).

Conclusions: Results support study hypotheses, suggesting that although jail participants are more drug-involved, drug use patterns may also be associated with county of recruitment. Implications include the need to: 1) consider both the community sampling place and setting when selecting subjects, 2) screen rural women for treatment needs and refer to interventions or treatment, as appropriate, and 3) improve service availability for rural women to reduce the likelihood of future drug use and related behaviors.

2461 | Real-world outcomes of patients with locally advanced or metastatic epithelioid sarcoma

Mrinal M Gounder[1], Priscilla Merriam[2], Ravin Ratan[3], Shreyaskumar R Patel[3], Rashmi Chugh[4], Victor M Villalobos[5], Mark Thornton[6], Brian A Van Tine[7], Amr H Abdelhamid[2], Preeti Joshi[8], Jennifer Whalen[8], Jay Yang[8], Anand Rajarethinam[8], Mei Sheng Duh[9], Priyanka J Bobbili[9], Lynn Huynh[9], Todor I Totev[9], Angela K Lax[9] and George D Demetri[2,10]

[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Dana Farber Cancer Institute and Harvard Medical School, Boston, MA; [3]The University of Texas M.D. Anderson Cancer Center, Houston, TX; [4]University of Michigan Comprehensive Cancer Center, Ann Arbor, MI; [5]University of Colorado Cancer Center, University of Colorado, Aurora, CO; [6]Sarcoma Foundation of America, Damascus, MD; [7] Washington University School of Medicine, St. Louis, MO; [8]Epizyme, Inc., Cambridge, MA; [9]Analysis Group, Inc., Boston, MA; [10]Ludwig Center at Harvard, Boston, MA

Background: Epithelioid sarcoma (ES) is an ultra-rare and aggressive subtype of sarcoma that typically affects young adults. Limited data are available on effectiveness and safety of conventional systemic therapies for treatment of advanced (unresectable and/or metastatic) ES.

Objectives: This study aimed to collect real-world (rw) data on outcomes of ES patients receiving at least first-line (1L) or 2 or more lines (2L+) of systemic therapies.

Methods: Retrospective chart review was conducted in patients with advanced ES who initiated systemic therapy between 2000-2017 at 5 US cancer centers. RECIST assessment was not performed in clinical practice, thus rw overall response rate (rwORR), duration of response (rwDOR), disease control rate (rwDCR; stable disease ≥32 weeks or response of any duration) and progression-free survival (rwPFS) were assessed by review of radiology reports. Overall survival (OS), rwDOR and rwPFS were estimated from start of therapy by Kaplan-Meier method. Endpoints were compared among patients treated with monotherapy vs combination therapy. Adverse events (AEs) resulting in treatment modification, discontinuation, hospitalization, permanent sequelae or death, were abstracted from medical records.

Results: Of 74 eligible patients, 53 (72%) were male, and 63 (85%) had metastatic ES. INI-1/BAF47 was undetectable in 90% of 41 tumors tested. Median (range) age at diagnosis was 33 years (11-76), and number of lines of therapy received was 2 (1-7). Anthracycline-based (54%) and gemcitabine-based (24%) regimens were used most often in 1L. 1L rwORR was 15%, rwDCR was 20%, median rwDOR was 3.3 months, median rwPFS was 2.5 months, and median OS was 15.2 months. Among 46 (62%) patients with evaluable data in 2L+, rwORR was 9%, rwDCR, was 20%, median rwDOR was 4.5 months, median rwPFS was 6.0 months, and median OS was 10.0 months. In 1L, the 20 (27%) patients who received monotherapy had a lower rwORR (5% vs 19%) and rwDCR (16% vs 22%) compared with patients who received combination therapy; a similar trend was observed in 2L+. Over 50% of patients had at least one AE; most frequently febrile neutropenia (14%), pain (9%), anemia, dyspnea, fever, thrombocytopenia and transaminitis (5% each).

Conclusions: Cytotoxic chemotherapies and tyrosine kinase inhibitors have limited efficacy in advanced ES and are associated with standard toxicities. This US-based rw study provides benchmarking treatment efficacy and safety data to understand the medical need of patients with advanced ES.

2476 | High pollen levels increase the likelihood of asthma-related inpatient admissions and emergency department visits in children with asthma: A matched case control study using patient-level claims and linked weather data

Elizabeth R. Packnett, Nicole M. Zimmerman, Caroline Hendriques and Debra E. Irwin

IBM Watson Health, Bethesda, MD

Background: Asthma is a common, chronic respiratory condition that affects about 6 million children in the United States. Previous ecologic studies showed increased asthma-related healthcare use when pollen levels are high.

Objectives: This study's objective was to describe the association between pollen levels and likelihood of asthma-related inpatient (IP) admissions or emergency department (ED) visits in children with asthma.

Methods: Children with asthma were identified from the MarketScan Commercial Database linked to pollen data in the IBM MarketScan Weather Database between March and October 2016. Those with an asthma-related IP admission or ED visit were cases; date of the IP/ED visit was the index date. Controls had no asthma-related IP/ED utilization during 2016 and the index date was the date of first asthma-related outpatient encounter in 2016. Cases were matched to controls at a 1:1 ratio on index month. Pollen levels (none, low, moderate, high) were assigned using the maximum pollen value in the five days before the index date. Adjusted odds ratios (OR) and 95% confidence intervals (CI) were calculated using conditional logistic regression to describe the likelihood of asthma-related IP/ED visits while controlling for baseline patient demographic and clinical characteristics related to asthma severity.

Results: 11,502 cases and controls were matched at 1:1 ratio; 63% were male. Likelihood of asthma-related IP/ED use was significantly higher when the maximum pollen level was high for both grass pollen (OR: 1.25; 95% CI: 1.09,1.43) and ragweed pollen (OR: 1.18; 95% CI: 1.02,1.38) vs. none. Moderate grass pollen levels were also associated with higher likelihood of asthma-related IP/ER visits (OR: 1.17; 95% CI: 1.09, 1.43).

Conclusions: Probability of an asthma-related IP/ER visit in children with asthma was significantly increased when grass or ragweed pollen levels were high after controlling for patient baseline demographic characteristics and clinical characteristics related to asthma severity. Further research is necessary to evaluate the role of seasonal variation in pollen type on the effectiveness of asthma medications and asthma-related healthcare utilization.

2478 | Clinical outcomes in the first year of life among infants of mothers with preeclampsia or gestational diabetes: An analysis of linked maternal and infant claims

Elizabeth R. Packnett, Helen V. Varker, Kristin A. Evans and Debra. E Irwin
IBM Watson Health, Bethesda, MD

Background: Preeclampsia and gestational diabetes mellitus (GDM) are common complications of pregnancy and are associated with infant morbidity. Rates of both conditions have increased in incidence in the US over the past two decades.

Objectives: This study's objective was to compare infant outcomes by maternal preeclampsia and GDM status in a cohort of infants linked to their mothers using claims data.

Methods: Women aged 15-50 with a singleton delivery between 1/1/2010 and 9/30/2015 and at least 12 months of continuous enrollment before and after the delivery date were identified in the MarketScan Commercial Database. Infants were linked to their mothers and required to be continuously enrolled for at least 12 months following their birthdate. Maternal preeclampsia and GDM were identified if a diagnosis of preeclampsia or GDM was present prior to delivery. Infant outcomes were assessed in 12 months following birth and stratified based on presence of maternal preeclampsia or GDM.

Results: 557,481 mother:infant pairs were identified (10,371 with maternal preeclampsia and 547,110 without preeclampsia; 49,202 with maternal GDM and 508,279 without GDM). Rates of cesarean section (Preeclampsia vs. no preeclampsia: 55.9% vs. 36.6%; GDM vs. no GDM: 47.1% vs. 36.0%), preterm delivery (Preeclampsia: 15.3% vs. 5.4%; GDM: 7.6% vs. 5.4%), low birthweight (Preeclampsia: 18.9% vs. 5.0%; GDM: 7.1% vs 5.1%), feeding problems (Preeclampsia: 38.3% vs. 32.3%; GDM: 33.9% vs. 32.3%), and delayed developmental milestones (Preeclampsia 1.3% vs. 0.6%; GDM: 1.4% vs. 1.2%) were significantly higher among infants with vs. without preeclampsia or GDM ($p<0.001$ for all). The proportion of infants with at least one inpatient admission (Preeclampsia: 42.5% vs. 26.5%; GDM: 29.6% vs. 26.9%) or emergency room visit (Preeclampsia: 29.9% vs. 23.8%; GDM: 25.9% vs. 23.7%) during follow-up were also significantly higher in infants with maternal preeclampsia or GDM ($p<0.001$ for all).

Conclusions: It is feasible to link mothers with their newborns to evaluate infant health outcomes based on maternal comorbidities. Infants with maternal preeclampsia or GDM have higher rates of events indicative of worse outcomes during their first year of life which were more pronounced among infants with maternal preeclampsia than infants with maternal GDM.

2515 | Using electronic data to validate acute pancreatitis diagnoses

Gregory A. Nichols[1], Anouk Deruaz-Luyet[2], Hristo Iliev[2] and Kimberly G. Brodovicz[3]
[1]Kaiser Permanente Northwest, Portland, OR; [2]Boehrniger Ingelheim GmbH, Ingelheim am Rheim, Germany; [3]Boehrniger Ingelheim Pharmaceuticals, Ridgefield, CT

Background: Recorded diagnoses of acute pancreatitis (AP) using ICD9/ICD10 codes only are often inaccurate in the United States resulting in limited utility for case identification.

Objectives: To validate ICD9/ICD10 diagnoses of AP recorded in the electronic medical record (EMR) of an integrated health system and to determine whether other recorded data could be included as covariates in an algorithm to more accurately identify cases of AP in common US EMR and claims data.

Methods: We identified random samples of potential cases of AP from inpatient diagnoses (any position) and from outpatient or emergency department diagnoses immediately preceding a hospitalization for any reason, and from hospitalizations for differential diagnoses (cholangitis and cholecystitis) in 2012-2018. We conducted an EMR

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

review to confirm cases meeting the Atlanta Classification or cases with a clinician recorded note of AP. Using confirmed cases as the "gold standard", we used logistic regression to develop EMR-based and claims-based algorithms using variables typically available in these data sources for identifying cases of acute pancreatitis. Algorithm performance was assessed with the C statistic, sensitivity, specificity, and positive and negative predictive value.

Results: Of the 550 patients with an AP diagnosis from any source, 467 (84.9%) met the gold standard as did 5 of 150 patients (3.3%) with a differential diagnosis. An AP diagnosis from any source had high sensitivity (98.9%), modest specificity (63.6%), and a reasonably good C statistic (0.813). A simple EMR-based model attained a C-statistic of 0.913 using an AP diagnosis (from any source), body mass index > 30 kg/m^2, serum lipase > 3 times upper limit of normal (ULN), and presence of diabetes. A simple claims-based model attained a C-statistic of 0.892 using an AP diagnosis (from any source) and dichotomous variables for whether a serum lipase test was performed and whether an abdominal ultrasound was performed; sensitivity was 89.8%, specificity 79.4%, and positive and negative predictive values of 90% and 79%, respectively. Use of ICD10 vs. ICD9 diagnoses appeared to only slightly improve case identification.

Conclusions: Consistent with available studies, we found diagnoses of AP do not accurately identify confirmed cases in US data sources. Our results suggest that the addition of a few variables typically available in existing data sources can increase accurate identification of AP cases, producing an area-under-the-curve (C statistic) of approximately 0.90 with high levels of sensitivity and specificity, and positive and negative predictive value.

2589 | Scale-up of amoxicillin dispersible tablet in the management of uncomplicated childhood pneumonia in Nigeria: A cost-benefit analysis

Charles E. Okafor[1], Obinna I. Ekwunife[2] and Sabina O. Nduaguba[3]
[1]*Griffith University, Nathan, Brisbane, Australia;* [2]*Nnamdi Azikiwe University, Awka, Nigeria;* [3]*University of Florida, Gainesville, FL*

Background: In Nigeria, about 19% of children under five die of pneumonia every year. The World Health Organisation (WHO) recommends the use of oral amoxicillin dispersible tablet (DT) as the first-line agent in its management. Some parents may be unable to procure the medication for a full treatment course due to other competing needs. In pursuant of SDG-3 and the African Union Agenda, 2063, there is need for external support.

Objectives: The principal objective of this study is to evaluate the cost and benefit of implementing amoxicillin DT in management of childhood pneumonia in Nigeria and to determine if scale-up of treatment will be worthwhile.

Methods: The study was a cost-benefit analysis using simulation-based decision-analytic Markov model for the Nigerian setting and a sample size of 34.6 million children at risk of having pneumonia. The study used retrospective data and cost analysis was from the payer's perspective. Amoxicillin DT was the intervention used in the study. Health outcome was expressed in terms of disability adjusted life years (DALY) averted and converted to monetary terms (benefits). Both cost and benefit were expressed in US dollars. Data was analysed using Microsoft excel 2007. Distribution appropriate to each parameter was used in the analysis.

Results: The mean cost of management of pneumonia was $0.47 while the mean DALYs averted was 0.006. With a 2018 GNI per capita of $1960, the Benefit-cost ratio (BCR) obtained is 31. The annual benefit of scale-up of amoxicillin DT will be $153 million per annum.

Conclusions: There is a significant benefit with amoxicillin DT in the management of pneumonia in a high prevalent country like Nigeria. Scale-up of treatment has the potential to generate high returns on investment and should be considered especially in far-to-reach areas in Nigeria.

2668 | Cost of illness studies using the clinical practice research datalink: A review of costing methodologies

Preveina Mahadevan[1], Elaine Stamp[1], Cormac Sammon[1] and Robert Carroll[2]
[1]*PHMR, London, United Kingdom;* [2]*BMS, London, United Kingdom*

Background: The linked Clinical Practice Research Datalink (CPRD)-Hospital Episode Statistics (HES) dataset is increasingly being used to investigate resource utilisation and costs associated with specific patient groups. In order to ensure this work produces reliable and comparable findings it is important that they use appropriate and consistent methods.

Objectives: To review methodologies used to estimate costs of resource utilisation from the CPRD.

Methods: The Ovid MEDLINE(R) database was searched for keywords relating to studies that investigated cost of illness (COI) using CPRD data. All COI studies published between 2017 to 2019 were identified and screened. Information on the source of cost data and the methodology used to attribute costs to episodes of healthcare resource use were extracted and reviewed. All data extraction was performed by two independent reviewers and all decisions were reached by consensus with an additional third reviewer.

Results: A total of 30 COI studies were identified. Of the 27 studies that costed GP visits, 26 (96%) used *Personalised Social Services Resources Unit (PSSRU)*. Of 25 studies that included GP prescription costs, 10 studies (40%) used the *Prescription Cost Analysis (PCA)*, 11 (44%) used the *British National Formulary (BNF)*, 3 (12%) used *NHS Drug Tariff*, one study used the *RESIP Gem- script Code Dictionary* and one study used the *Dictionary of Medicines and Devices browser*. One study used *PCA* and *BNF data* and one used *PCA* and *NHS Drug Tariff data*. Studies which were non-specific regarding the source of cost data included one for GP data and two for prescriptions. Of 26 studies that costed inpatient admissions, 17 (65%) used *NHS reference costs*,

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

7 (27%) used the *National Tariff* and 2 (8%) used both these sources. Amongst these, 20 (77%) stated they additionally used the *Healthcare Resource Grouper (HRG) software*. Of only 18 studies that costed outpatient visits, 16 (89%) used *NHS reference costs* where 9 studies (56%) defined the cost by speciality, 2 (11%) used *National tariff* and one study used *PSSRU*.

Conclusions: While there is some consistency in the methodologies used to attach costs to resource utilisation data from the CPRD, variation in the choice of sources of unit cost data and their application was observed. Incomplete reporting of methodologies also limited the extent to which the consistency of approaches could be determined. A more standardised and transparent approach to calculating total and relative costs using the CPRD-HES database is needed, this will allow for comparison of results and effective evaluation of methodologies.

3765 | Psychometric assessment of Urdu version of WHOQOL HIV BREF among Pakistani HIV infected patients

Ali Ahmed and Juman Dujaili
Monash University Malaysia, Jalan Lagoon Selatan, Malaysia

Background: The assessment of the health-related quality of life (HRQoL) in people living with HIV (PLHIV) has become crucial to evidence-based practice

Objectives: The current analysis was aimed to translate and examine the psychometric properties of the Urdu version of WHOQOL HIV BREF among HIV patients in Pakistan.

Methods: The standard forward-backward translation technique was used for Urdu translation of the WHOQOL HIV BREF. Based on the principle of 5 subjects minimally for each item, a sample of 182 patients were recruited by employing a universal random sampling technique. Data were analyzed to measure reliability, internal consistency, known-group, and multiple linear regression.

Results: High internal consistency was found for all WHOQOL HIV BREF facets scales as demonstrated by higher reliability coefficients (Sum scale: α = 0.93, Physical Health: 0.931; Psychological Health: 0.93; Level of Independence: 0.93; Social Relationships: 0.93; Environment Health: 0.93; Spiritual Health: 0.93). The test-retest reliability revealed a statistically significant interclass correlation coefficient ranged from 0.88-0.98 ($p<0.001$). In known group validity, subjects with lower CD4 counts had lower scores for all six domains ($p<0.001$). In similar, symptomatic participants had significantly lower scores than asymptomatic participants on the physical, psychological, social relationship and independence domains ($p<0.05$). Spearman's correlation tests indicated a significant inverse correlation ($P<0.001$) between HIV stages and all six domains of HIV-BREF scale, explaining higher stages associated with poor quality of life. Results also revealed a statistically significant positive correlation of all six domains with CD4 count ($P<0.001$), exhibiting patients with higher CD4 count will have higher mean scores of all six domains. When all domains were assessed together via Multiple linear regression analysis; only physical, psychological health and environment health domains were found significantly associated with higher CD4 count (Beta= 0.121, $P<0.001$, Beta=0.103, $P=0.002$, and Beta= 0.032, $P=0.032$).

Conclusions: The findings offer promising support for the use of the Urdu version of the WHOQOL HIV Bref among Pakistani HIV patients as a reliable and valid instrument.

3783 | Policy options for improving insulin affordability

Stacie B Dusetzina[1], Laura Keohane[1], Haiden Huskamp[2] and Nancy Keating[2]
[1]*Vanderbilt University School of Medicine, Nashville, TN;*[2]*Harvard Medical School, Boston, MA*

Background: Insulin affordability is a major concern in the United States. Several policy options are currently being debated to reduce out-of-pocket spending by older adults on the Medicare Part D program.

Objectives: We sought to summarize Medicare Part D plan design for insulin in 2019 and estimate expected Medicare beneficiary out-of-pocket spending on long-acting insulin under Part D's current benefit and under a proposed Part D redesign that eliminates the coverage gap and extends the initial coverage phase to an out-of-pocket spending limit of $2,000.

Methods: We used formulary files for all Medicare Part D plans available in 2019. We calculated expected out-of-pocket spending for 12 fills of long-acting insulin using median point-of-sale prices and cost-sharing arrangements used by Part D plans in 2019. We applied the 2020 Part D spending limits to determine when beneficiaries would move from the initial coverage phase to the coverage gap, where out-of-pocket spending changed from flat copayments to coinsurance (paying a percentage of the drug's price). We re-estimated out-of-pocket spending on insulin under two simplified designs: copayment only and coinsurance only.

Results: In 2019, most plans offered insulin using flat copayments for beneficiary cost sharing in the initial coverage phase, switching to coinsurance in the coverage gap. Based on an average per-fill point-of-sale price of $615 (across all long-acting insulin products), beneficiaries would expect to spend $1,115 out-of-pocket in 2020 for 12 fills of long-acting insulin based on the most common plan cost-sharing structure in 2019. With no coverage gap and an extension of the initial coverage phase to an out-of-pocket limit of $2,000, beneficiaries needing insulin would save $611 per year relative to the status quo if plans elected to use a flat copayment for cost-sharing. However, beneficiaries would pay $730 more under these proposed reforms if plans switch to coinsurance for the initial coverage phase.

Conclusions: Recent federal proposals to modify Medicare Part D could result in higher out-of-pocket spending for beneficiaries

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

needing insulin if plans elect to use coinsurance instead of flat-fee copayments in the revised benefit. This could have a negative impact on insulin access and adherence. As policymakers Medicare Part D, they should aim to provide affordable cost sharing for high-value, chronic use medications such as insulin.

3785 | Medicare part D plan coverage of brand-name drugs when generics are available

Stacie B Dusetzina[1], Juliette Cubanski[2], Leonce Nshuti[1], Sarah True[2], Jack Hoadley[3], Andrew Roberts[4] and Tricia Neuman[2]
[1]*Vanderbilt University School of Medicine, Nashville, TN;* [2]*KFF, Washington, DC;* [3]*Georgetown, Washington, DC;*[4]*Kansas University Medical Center, Kansas City, KS*

Background: Medicare Part D provides prescription drug coverage for older adults in the United States. There have been recent concerns that Part D plans might prefer branded drugs over generics, driving up spending for beneficiaries and taxpayers.
Objectives: To quantify how often Medicare Part D plans offer preferred formulary placement of brand drugs over their generic equivalents. We also evaluate cost implications for Medicare and beneficiaries when plans favor brand drugs to generics.
Methods: We evaluated Medicare Part D formulary coverage of generic and brand-name drugs from 2012 to 2019. We identified exact brand-generic pairs based on the RxNorm product description in each year. We determined the relative frequency of formulary coverage patterns of the brand-generic pairs: only brand covered, only generic covered, and both covered. The unit of analysis is "plan-product combination," where each observation represents the coverage status of one product for one plan. We also estimated differences in product prices and out-of-pocket costs when both brands and generics were offered on a formulary.
Results: Only 0.9% of observations (of 4,176,772 plan-product observations) correspond to brands covered and generics excluded. Conversely, 84% of observations correspond to generics included and brands excluded, while 15% of observations correspond to both generics and brands covered by the same plan. For the 15% of product-plan combinations where both branded and generic versions of the same drug product were covered on the same plan formulary, we found that 1% of brands were placed in lower cost-sharing tiers than their generic equivalents; 40% of generics were placed on a lower cost-sharing tier than brands; and 59% of brands and generics were placed on the same tier. When brands and generics were on the same tier, mean list prices were $349 (SD:1,350) for brands and $197 (SD:$666) for generics. In such settings, beneficiary cost sharing took the form of copayments instead of coinsurance in 80 percent of observations resulting in no difference in out-of-pocket costs for consumers.
Conclusions: Despite recent reports, we find little evidence of Part D plan preference for brands over generics. While preferential formulary placement of brands and/or exclusion of generic drugs was not common, we found that a small number of brand drugs were indeed subject to higher rates of preferential treatment on Part D plan formularies. Better inclusion and coverage of these generic drugs, and all excluded or non-preferred generic drugs on Part D formularies, could present an opportunity for cost savings to the Medicare program as well as its beneficiaries.

3836 | Disease severity, comorbid conditions, treatment patterns, and flares in adults with systemic lupus erythematosus in the United Kingdom: A real-world observational retrospective cohort analysis

Julia Langham[1], Volkan Barut[2], Mihail Samnaliev[1], Sue Langham[1], Sharada Weir[1], Xia Wang[3], Barnabas Desta[3] and Edward R Hammond[3]
[1]*Maverex Limited, Manchester, United Kingdom;* [2]*BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom;* [3]*BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD*

Background: There is limited real-world evidence describing the presentation and treatment patterns of systemic lupus erythematosus (SLE) in the United Kingdom (UK).
Objectives: To characterize disease severity, comorbid conditions, treatment patterns, and flares in a longitudinal cohort of adults with SLE in the UK.
Methods: Patients aged ≥18 years with SLE were identified in the Clinical Practice Research Datalink - Hospital Episode Statistics database from January 1, 2005, to December 31, 2017. Patients were required to have ≥12 months of data before and after index date (date of earliest SLE diagnosis available). SLE disease severity and flares were classified as mild, moderate, or severe using adapted claims-based algorithms that use SLE-related conditions (eg, end-stage renal disease), medications (eg, antimalarials, immunosuppressants, and corticosteroids), and health service use (eg, hospitalizations and emergency department visits).
Results: Of 802 patients with SLE, 369 (46.0%) had mild, 345 (43.0%) had moderate, and 88 (11.0%) had severe SLE at baseline. In total, 692 (86.3%) patients were treated with SLE medications in the first year after SLE diagnosis. Among the total population (802), 557 (69.5%) patients received antimalarials, 203 (25.3%) received immunosuppressants, and 416 (51.9%) received corticosteroids (prednisolone); patients may have received ≥1 type of drug. Information on biologic use in hospitals is unavailable in these data. The mean (standard deviation [SD]) time to initiating any medication from index date was 177 (385.3) days. The median time to first flare from index date was 63 days (95% confidence interval 57-71). A majority of patients (750/802, 93.5%) experienced ≥1 flare during follow-up; the first flare was mild for 73.2% of patients (549/750), moderate for 15.5% (116/750), and severe for 11.3% (85/750). The mean (SD) annual overall flare rate in the first year after index date was 3.5 (2.5) (mild flares: 2.6 [2.5]; moderate flares: 0.7 [1.5]; severe flares: 0.2 [0.6]). A shorter median

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

time to first flare was significantly associated with moderate or severe disease (P<0.001) and the presence of comorbid conditions (P<0.001).

Conclusions: Our findings suggest some delay in SLE treatment initiation in the UK. Most patients with SLE experience flares within 2 months from diagnosis. Early treatment may delay or reduce the severity of the first SLE flare after diagnosis and may translate to slower disease progression, lower organ damage accrual, and better outcomes.

3860 | Health care utilization and costs in adults with systemic lupus erythematosus in the United Kingdom: A real-world observational retrospective cohort study

Mihail Samnaliev[1], Volkan Barut[2], Sharada Weir[1], Julia Langham[1], Sue Langham[1], Xia Wang[3], Barnabas Desta[3] and Edward R. Hammond[3]
[1]Maverex Limited, Manchester, United Kingdom; [2]BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; [3]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD

Background: There is limited real-world evidence demonstrating the long-term direct costs associated with systemic lupus erythematosus (SLE) in the United Kingdom (UK).

Objectives: To describe health care resource utilization and costs in adults with SLE in the UK over time and document costs by disease severity and type of encounter, including primary care, hospitalizations, outpatient visits, and prescription drugs.

Methods: Patients aged ≥18 years with SLE were identified in the linked Clinical Practice Research Datalink - Hospital Episode Statistics database from January 1, 2005, to December 31, 2017. Patients were required to have data from ≥12 months before and after the index date, defined as the date of earliest diagnosis available in the data set. Patients were classified as having mild, moderate, or severe disease using an adapted claims-based algorithm. Costs were calculated in 2017 UK pounds from the UK national health care system perspective. We estimated all-cause health care costs and incremental costs associated with each year of follow-up compared with a baseline year (3 years before index) using each patient as his or her own control and adjusting for age, sex, disease severity, and comorbid conditions.

Results: Of the 802 patients identified, 369 (46.0%) had mild SLE, 345 (43.0%) had moderate SLE, and 88 (11.0%) had severe SLE. The mean all-cause cost increased in the 3 years before diagnosis and, in the first year after diagnosis, amounted to £7532 (standard deviation [SD] £9634). This cost varied by disease severity: mild SLE, £5221 (£8064); moderate SLE, £8323 (£9846); and severe SLE, £14,125 (£11,267). Adjusted total mean annual increase in costs per patient in the overall study population was £4476 (95% confidence interval £3809-5143) greater in the year of diagnosis compared with the baseline year (P<0.0001), adjusted for age, sex, disease severity, and comorbid conditions. Primary care utilization was the leading component of costs during the first year after diagnosis, followed by prescriptions, outpatient care, and inpatient care. Information on biologic use in hospitals is unavailable in these data.

Conclusions: The direct costs of health care for patients with SLE in the UK are substantial and persist over the years after diagnosis. Patients with moderate or severe SLE have higher all-cause costs over time compared with patients with mild SLE. Earlier diagnosis and treatment may reduce disease severity and occurrence of comorbidities, and the associated high health care costs.

3863 | Direct medical burden of antimicrobial resistant healthcare associated infections: An analysis with propensity score matching method

Xinliang Liu[1], Dan Cui[2], Hao Li[2], Quan Wang[2], Zongfu Mao[2], Liang Fang[3], Nili Ren[4] and Jing Sun[5]
[1]The University of Manchester, Manchester, United Kingdom; [2]Wuhan University, Wuhan, China; [3]The Third People's Hospital of Hubei Province, Wuhan, China; [4]Hubei University of Medicine, Wuhan University, China; [5]CAMS & PUMC, Beijing, China

Background: Antimicrobial resistance (AMR) and healthcare-associated infection (HAI) are among the biggest global public health challenges, and overlap widely. These infections cause significant morbidity and mortality, put pressure on health systems, and incur rising direct and indirect costs.

Objectives: To analyze the direct medical burden attributable to antimicrobial-resistant healthcare-associated infections in Chinese public tertiary hospitals, and aimed to inform both the medical regulators and hospital managers for better control of HAI and containment of AMR.

Methods: The propensity score matching method (γ=0.25σ, nearest neighbor 1:1 matching) was applied to conduct a retrospective cohort study in five public tertiary hospitals in the Hubei province of China during 2013-2015. Descriptive analysis, Pearson Chi-Square test, Mann-Whitney U test, Wilcoxon signed-rank test and paired/independent Z/T test were conducted. The statistically significant level was set at P < 0.05.

Results: From 2013 to 2015 in overall, the additional total medical expenditure per HAI-AMR inpatient was US$ 15 557.25 compared with that of the non-HAIs, and the additional length of per hospital stay of the HAI-AMR inpatient was 41 days compared with that of the non-HAIs (P<0.001).

Conclusions: In combination with AMR, HAI caused significant additional medical expenses and affected the turnover rate of hospital beds. Most of the increased medical costs fell to patients and their families. These findings call for more effective control of HAI and containment of AMR. A national study is needed to estimate the medical, social and economic burden of HAI in combination with AMR.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 3910 | The use of real-world evidence in economic assessments of pharmaceuticals in the United States

Woojung Lee, Victoria Dayer, Boshen Jiao, Josh Carlson, Beth Devine and David Veenstra
University of Washington, Seattle, WA

Background: There is increasing interest in expanding the use of real-world evidence (RWE) for pharmaceuticals with the recent FDA guidance on how drug companies may communicate health care economic information with payers. Health care decision makers and producers of RWE are still faced with uncertainty, however, about how much and what type of RWE should be used in technology assessment. A clearer understanding of recent trends in RWE use can provide insight to this issue.

Objectives: To assess the use of real-world evidence (RWE) in economic assessment of drugs by the Institute for Clinical and Economic Review (ICER).

Methods: We retrieved final evidence reports of pharmaceuticals published by ICER between 2014 and 2019 and reviewed the cost-effectiveness and budget impact analysis in the reports. We calculated the total number of RWE uses and the proportion of model parameters informed by RWE per report to estimate the absolute and relative frequency of RWE use, respectively. We classified model parameters into 15 categories based on their attributes and then examined which parameter category was informed by each RWE to classify the reason for RWE use. Finally, we characterized RWE by study design, data source, and sponsor type using frequency distribution.

Results: We identified 33 final evidence reports, all of which used RWE; the mean RWE use per-report was 12 (range: 4 - 26). The average proportion of model inputs informed by RWE per-report was 32.7% (range: 4.1% - 76.9%). Real-world evidence was most commonly used for disease progression parameters (28.7%) and healthcare resource utilization and costs (21.1%), but rarely used for drug-specific clinical outcomes such as effectiveness (1.5%), adverse drug event rates (0.5%), and discontinuation rates (1.2%). The most frequently used study design and data source were retrospective cohort (56.6%) and registry data (41.4%). About a third (30.2%) of RWE was industry-sponsored.

Conclusions: Real-world evidence has been commonly used to inform pharmaceutical economic analyses by ICER, but there has been relatively limited use to inform comparative drug effectiveness.

3917 | Time in therapeutic range (TTR) values among incident warfarin users and predictors of TTR

Kebede Beyene, Patricia Näslund, Amy Hai Yan Chan and Jeff Harrison
School of Pharmacy, the University of Auckland, Auckland, New Zealand

Background: Time in the therapeutic range (TTR) of international normalised ratio (INR) 2.0-3.0 is a common measure of warfarin anticoagulation quality. TTR value above 60% indicates optimal anticoagulation control, and adverse outcomes increase when TTR ≤ 60%. The quality of long-term anticoagulation and factors affecting anticoagulant control in patients taking warfarin have not been fully explored in New Zealand (NZ).

Objectives: The aim of this study was to determine TTR values in patients who newly initiated warfarin therapy between January 2006 and December 2011 in Auckland, NZ, and to identify the factors affecting TTR in these patients.

Methods: This was a population-based, retrospective cohort study. Information on demographics, warfarin use, and INR values were obtained from national healthcare databases for each patient. Adults (age ≥18 years) who newly initiated warfarin treatment between January 2006 and December 2011 and had more than five INR tests during this time period were included. TTR was computed using the Rosendaal method. Patients were classified into two groups according to their TTR values (>60% vs. ≤60%) and the characteristics of these groups were compared. Multivariable logistic regression was used to examine the association between patient characteristics (gender, age, ethnicity, deprivation index) and TTR.

Results: A total of 4280 patients were included in this study. The mean age of patients was 65±12 years, and 60.3% of them were male. The mean and median follow-up time were 2.76±1.7 and 2.73 years, respectively. The mean TTR was 55.3±17%, and 58.1% of patients had sub-optimal TTR (≤60%). Some patient characteristics were significantly associated with TTR. Age 65-74 years (Adjusted odds ratio (AOR)=1.198, 95% CI 1.027-1.396, p=0.021) was predictive of optimal TTR. Māori (AOR=0.491, 95% CI 0.403-0.597, p<0.001)), Pasifika (AOR=0.516, 95% CI 0.390-0.682, p<0.001), or Asian ethnicity (AOR=0.715, 95% CI 0.547-0.936, p=0.014), and living in the most deprived area of Auckland (AOR=0.716, 95% CI 0.581-0.884, p=0.002) were predictive of sub-optimal TTR (≤60%).

Conclusions: Our study demonstrated that a significantly large proportion of patients on warfarin had sub-optimal TTR. Age, ethnicity and deprivation index were significant predictors of TTR. Identifying these risk factors for suboptimal INR control can help clinicians focus their INR monitoring on those who are most at risk.

3946 | The prevalence of sun protective behaviors across different age groups in the US population: Findings from the 2015 US Health Interview Survey

Ching-Yuan Chang, Haesuk Park and Jenny Lo-Ciganic
University of Florida, College of Pharmacy, Gainesville, FL

Background: The goal stated in the US Healthy People is that third-quarters of adults will use sun protection by 2020 in order to reduce the risk of skin cancer. Prior studies largely focused on examining sun protective behaviors across gender and race. However, little is known about whether/how sun protective behaviors differ by age.

Objectives: We examined the association between age and sun protective behaviors, adjusting for potential confounders.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This cross-sectional study included a nationally representative of US adults without any skin cancer from the 2015 National Health Interview Survey. Age was categorized into 18-29, 30-49, 50-69, and ≥70 years old. Sun protective behaviors included: 1)wearing sun-protective clothing, 2)shade use, 3)hat use, 4)sunscreen use, and 5)infrequent indoor tanning device use. We estimated the national prevalence for having sun protective behaviors (and any individual behavior) by age group. We used a weighted multivariable logistic regression model to examine the association between age and sun protective behavior adjusting for sociodemographic and health status factors (e.g., smoking). Adjusted odds ratios(aORs)with 95% confidence interval(95%CI)were reported.

Results: Among eligible 236,234,809 participants in 2015, 21.6% aged 18-29, 34.6% aged 30-49, 31.8% aged 50-69, and 12.0% aged ≥70. When compared with participants aged 18-29, participants aged 50-69 (aOR=1.83, 95%CI=1.49-2.25) and aged ≥70 (aOR=6.24, 95% CI =4.07-9.58) were associated with having more sun protective behaviors. Findings were consistent for wearing sun-protective clothing (age 50-69:OR=1.61, 95%CI=1.45-1.79;aged ≥70:OR=3.64, 95% CI=3.21-4.12), shade use (age 50-69:OR=1.41, 95%CI=1.27-1.56;aged ≥70:OR=2.14, 95%CI=1.88-2.43), and using indoor tanning device(age 50-69: OR=0.64, 95%CI=0.54-0.74; aged ≥70: OR=0.22, 95% CI=0.17-0.28).

Conclusions: Younger Americans were less likely to have sun protective behaviors compared to older adults. The findings suggest that healthcare providers may encourage younger individuals wearing sun-protective clothing and shade protection, and reducing indoor tanning exposure. Environmental and policy strategies can focus on provision of shade in school and recreational settings.

4009 | Pharmaceutical care in Chinese public tertiary hospitals: Findings from the 4th National Healthcare Improvement Initiative Survey

Mingshuang Li
School of Public Health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Pharmaceutical care has been playing an increasingly critical role in Chinese hospitals. However, evidence about the most recent development of pharmaceutical care in China is limited.

Objectives: To analyze the current situation of pharmaceutical care and the capacities of the pharmacists in Chinese public tertiary hospitals.

Methods: All on-duty pharmacists of 143 public tertiary hospitals responded to the Likert-5 pre-set online questionnaire about their pharmaceutical care capacities, and their respective hospitals valued pharmaceutical care in clinical practice from March 18 to 31,2019. The study measured the appraisals of the responding pharmacists as positive ("strongly agree" and "agree") or negative ("neither agree nor disagree", "strongly disagree" and "disagree") results, and performed a descriptive analysis of the responding pharmacists and un-conditional multivariate binary logistic regression analysis to predict the influencing factors of the pharmacists' appraisals of pharmaceutical care. The dependent variable was transformed into binary categories and assigned 1 = positive response,0 =negative response. The independent variables included the characteristics of sample hospitals and the responding pharmacists.

Results: The survey retrieved 10 815 valid responded questionnaires.74.5%, 67.5% and 65.0% of the responding pharmacists made a positive self-appraisal of their abilities of communication with patients and doctors, reviewing prescriptions and communication with particular patients.65.5% had a positive appraisal of their respective hospitals to conduct active monitoring of the clinical use of new medicines, and 68.9% admitted that their respective hospitals value the clinical pharmaceutical care. The doctor degree and senior academic rank of the responding pharmacists, as well as maternal and child hospitals were predictors of higher appraisals of the responding pharmacists about their pharmaceutical care capacities, and their respective hospitals valued pharmaceutical care (all *ORs*>1.5, *P*<0.05).

Conclusions: The study suggested that there is a need to strengthen the pharmacy education, training and staffing of pharmacists with improved professional skills to offer value-added specialized pharmaceutical care in Chinese public hospitals. Patient-centred and interdisciplinary interactions in medical practice should be promoted. There is also a need for public hospitals to provide a platform for the achievement of the professional values of high-quality pharmacists at different carrier development stages.

4119 | Patient, provider and formulary characteristics associated with initiation of a SGLT2i or GLP-1RA among medicare beneficiaries with type 2 diabetes: A retrospective cohort study

Jing Luo, Inmaculada Hernandez, Joseph Gabriel and Walid Gellad
University of Pittsburgh, Pittsburgh, PA

Background: Factors predicting intensification to an SGLT2 inhibitor (SGLT2i) or GLP-1 receptor agonist (GLP-1RA) have not been previously described.

Objectives: To determine factors associated with initiation of a SGLT2i or GLP-1RA among Medicare beneficiaries with type 2 diabetes on prior oral therapy

Methods: Using prescription claims and formulary data from a random 5% sample of all Medicare beneficiaries, we sought to assess the association between plan generosity and risk of initiating a SLT2i or GLP1-RA. Our cohort included patients with diagnosed type 2 diabetes who had at least 1 prescription claim for any oral diabetes medication (excluding SGLT2i) in the 180 days before the start of follow-up (1/1/2015). Patients were excluded if they died before 12/31/16 or if they filled any insulin, SGLT2i or GLP-1RA before 1/1/2015. We developed multivariable logistic regression models controlling for age, race, region, prior medication use, claims-based measures of diabetes severity and clinical comorbidities, provider specialty and 2 measures of formulary restrictiveness.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of 103,112 eligible patients, 5,076 (4.9%) initiated a SGLT2i or GLP-1RA between 1/1/15 - 12/31/16. After adjusting for baseline demographic, geographic, provider and clinical characteristics; patients enrolled in plans covering 2 or more drugs in tiers 1-3 were more likely (adjusted odds ratio [aOR] 1.18 [95% CI, 1.05 to 1.32] to initiate one of these target medications than patients enrolled in plans covering 0 drugs in preferred tiers. There was no significant differences in use of SGLT2i or GLP-1RA comparing patients with 0 versus 2 or more drugs covered without prior authorization or step therapy requirements.

Conclusions: After controlling for a large number of clinical and other factors, patients with type 2 diabetes on prior first or second-line therapy with more generous prescription drug coverage were more likely to initiate a SGLT2i or GLP-1RA.

4121 | Coverage, formulary restrictions and average retail prices of SGLT2 inhibitors and GLP-1 receptor agonists across medicare part D plans in 2019

Jing Luo, Robert Feldman, Scott Rothenberger and Walid Gellad
University of Pittsburgh, Pittsburgh, PA

Background: Access to SGLT2 inhibitors (SGLT2i) and GLP-1 receptor agonists (GLP-1RA) may be limited by high drug prices and insurance related barriers including prior authorization or step therapy requirements. These barriers are particularly challenging for seniors covered under Medicare's prescription drug benefit (Part D).

Objectives: To determine coverage, formulary restrictions and average retail prices of SGLT2i and GLP-1RA across Medicare Part D Plans in 2019

Methods: We used Q1 2019 national Part D Formulary files to examine: 1) the proportion of plans (weighted by enrollment) that cover a SGLT2i or GLP-1RA without prior authorization or step therapy and 2) the average retail price [IQR] for a 30-day supply of each medication.

Results: Among 3,992 plans, the weighted percent of plans that covered canagliflozin, dapagliflozin and empagliflozin without prior authorization or step therapy was 53.2% (95% CI: 49.1 to 57.4), 63.7% (95% CI: 60.1 to 67.3) and 95.4% (95% CI: 94.3 to 96.4), respectively. Coverage without prior authorization or step therapy for GLP-1RA of ranged from 3.2% (95% CI: 1.8 to 4.6) for lixisenatide to a high of 87.4% (95% CI: 85.5 to 89.3) for dulaglutide. The mean retail price for a 30-day supply of a SGLT2i or a GLP-1RA ranged from $295 [285-303] (ertugliflozin) to $512 [501-527] (canagliflozin) and $641.38 [629-657] (lixisenatide) to $946.17 [930-968] (liraglutide), respectively.

Conclusions: In 2019, coverage without prior authorization and step therapy for SGLT2i and GLP-1RA were mixed across Part D plans, with most plans covering at least one drug in each class without either type of restriction. Cost sharing (i.e. high out-of-pocket payments) may be more problematic for patients than either prior authorization or step therapy.

4146 | Cost-effectiveness of Taxane/platinum and doxorubicin/platinum combination therapies in adjuvant treatment of endometrial cancer

Swetha Srinivasan, Joehl T Nguyen and Megan C Roberts
University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Surgical procedures (e.g. total hysterectomy) are used for treatment of endometrial cancer, and postoperative adjuvant chemotherapy is recommended to reduce recurrence in this context. Recent clinical trial data has shown that (i) docetaxel/cisplatin (DOC/CIS), and (ii) doxorubicin/cisplatin (DOX/CIS) regimens are non-inferior compared to the standard adjuvant treatment in endometrial cancer, paclitaxel/carboplatin (PAC/CAR) in terms of overall survival (OS) and progression-free survival (PFS); however, these therapies differ in costs and safety profile which may affect patient quality of life.

Objectives: To evaluate the cost-effectiveness of DOC/CIS and DOX/CIS combination therapies compared to standard PAC/CAR therapy in adjuvant treatment of endometrial cancer to guide decision-making on which combination therapy should be preferred for postoperative adjunct therapy to reduce recurrence.

Methods: We constructed a three-state Markov decision analytic model for progression in endometrial cancer to estimate the cost-effectiveness of three combination therapies (DOC/CIS, DOX/CIS, PAC/CAR) over a 5-year time horizon from a third-party payer perspective. The cohort consisted of 62,000 women presenting the prevalence of those receiving standard surgical treatment for endometrial cancer in the United States per year. Input parameters (transition probabilities and health utilities) and costs were derived from published literature and Medicare Average Selling Price (ASP) data. Outcomes evaluated included mean costs (2019 USD), quality-adjusted life years (QALYs), and incremental cost-effectiveness ratios (ICERs). All outcomes were discounted at 3% annually, and deterministic one-way sensitivity analysis was conducted to assess robustness of the model.

Results: The model produced mean costs of $65,221, $91,829 and $76,563, and yielded 3.40, 3.08 and 3.18 QALYs per person for the DOC/CIS, DOX/CIS and PAC/CAR strategies, respectively. The ICER for DOC/CIS dominated the PAC/CAR strategy, due to lower costs and better outcomes, whereas the ICER for DOX/CIS was dominated by the PAC/CAR strategy, due to higher costs and poorer outcomes. Deterministic one-way analysis confirmed that the base-case results were robust to model assumptions on costs and health utilities.

Conclusions: DOC/CIS is cost-effective for postoperative adjuvant treatment of endometrial cancer and may be an alternative to the standard PAC/CAR therapy.

4158 | Cost-related nonadherence for prescription medications: A cross-sectional study in Jordan

Abdallah Y. Naser
Isra University, Amman, Jordan

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background: Cost-related nonadherence (CRN) to medications is a commonly encountered problem by many patients and specifically among elderly patients who use different multiple medications. Despite that there are many factors that have influence patients' adherence to their therapy, cost of medications is considered as one of the most important contributor to this problem.

Objectives: To explore the prevalence of medications cost-related nonadherence in Jordan and its associated individual characteristics.

Methods: A cross-sectional study was conducted between February 2019 and May 2019 in Jordan to explore the prevalence of medications cost-related nonadherence in Jordan and its associated individual characteristics. Prevalence of medications cost-related nonadherence was estimated by dividing the number of respondents who confirmed that their adherence to their medications was affected by their cost on the total number of the study participants. Logistic regression was used to determine factors that are associated with medications cost-related nonadherence.

Results: A total of 1,129 participants were involved in this study from different governorates in Jordan. The prevalence rate of cost-related nonadherence is around 29.6%. Participants who are married or widowed found to have higher odds of being no adherent due to medications cost with odds ratio of 1.55 (1.19 - 2.00) and 1.95 (1.20 - 3.15) respectively. Having lower educational level was associated with medications cost-related nonadherence, and having college, bachelor degree or higher studies qualification were important protective variable and reduced the odds of nonadherence with around 42% (odd ratio of 0.58 (0.45 - 0.75)). Being retired was associated with higher odds of being non-adherent (2.20 (1.49 - 3.27)). Having higher income was another protective variable from being non-adherent due to medications cost and decrease the probability of this problem by 55% (0.45 (0.21 - 0.97)). In addition, patients' evaluation of their health status was another important variable that influenced patients' adherence positively, as patients who reported that their health status is very good or excellent have 62% of being more adherent compared to other patients (0.38 (0.28 - 0.52)).

Conclusions: The prevalence of cost-related nonadherence is high in Jordan. Married, widowed, retired patients and patients with low educational level were the most commons categories that affected by cost of medications. Higher focus should be directed towards these categories to improve their adherence towards their therapy as it is connected to better health outcomes.

4177 | Comparison of symptoms, treatments and healthcare resource utilization in patients with multiple sclerosis by sex in a real world cohort in the United States

Ia Topuria, Cristi Cavanaugh, Greg Donadio, Kathryn Starzyk and Rich Gliklich

OM1, Inc., Boston, MA

Background: Autoimmune diseases like multiple sclerosis (MS) disproportionately impact women. Research suggests MS susceptibility and relapses may differ due to mechanisms underlying sex differences in disability progression. Such differences may impact disease phenotypes, which in turn, increase need for clinical care and healthcare resource utilization (HRU).

Objectives: To compare symptoms and HRU of MS patients identified from a large, representative database of linked EMR-claims data by sex.

Methods: The OM1 Real World Data Cloud (OM1, Boston, MA) collects and links structured and unstructured data including extensive clinical and administrative claims data on patients from a variety of practice types across the US starting in 2013. This study included MS patients ages ≥18 on the index date defined as the earliest of first observed MS diagnosis or disease-modifying therapy (DMT) initiation who had 12 months of data available after the index date (observation period). MS symptoms (by diagnosis codes), treatments and HRU were assessed during the observation period and stratified by sex with significant differences defined as $p<0.05$ from chi-square tests.

Results: As of November 2019, 306,607 MS patients met inclusion criteria. Mean age was 50.6 years (SD: 13.1), 76.6% were female and 85.8% of patients with known race were white. A higher proportion of males vs females had evidence of the following signs and symptoms during the observation period (all $p<0.001$): gait abnormality (13.8% vs 11.7%), muscle weakness (10.5% vs 9.0%), ataxia (4.7% vs 3.6%), sexual dysfunction (6.1% vs 0.04%) and urinary retention (6.9% vs 3.8%). In contrast, a higher proportion of females vs males experienced the following (all $p<0.001$): depressive disorder (21.7% vs 16.5%), burning, numbness, or tingling (13.1% vs 11.1%), fibromyalgia/myalgia and myositis (7.9% vs 3.4%) and malaise and fatigue (20.9% vs 18.5%). Males were more likely to have a hospitalization (20.4% vs 18.4%, $p<0.001$) and females were more likely to have an emergency room or urgent care visit (21.9% vs 20.6%, $p<0.001$). More females used steroids (12.0% vs 10.0%, $p<0.001$), while more males used a DMT (22.2% vs 21.8%, $p=0.014$).

Conclusions: Depression and sensory-related symptoms were more common in women, while men were more likely to have symptoms related to impaired coordination and urinary and sexual dysfunction. Both groups experienced muscle-related symptoms. While initial analyses indicate differences in HRU by sex, research is needed to characterize the impact on the clinical and economic burden of MS.

4242 | Effect modifications on risk of hospitalization due to heart failure in type 2 diabetes patients receiving dapagliflozin versus empagliflozin

Shih-Chieh Shao[1,2], Kai-Cheng Chang[3,2], Hui-Yu Chen[3], Yuk-Ying Chan[4], Yea-Huei Kao Yang[2] and Edward Chia-Cheng Lai[2]

[1]Keelung Chang Gung Memorial Hospital, Keelung, Taiwan; [2]National Cheng Kung University, Tainan, Taiwan; [3]Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; [4]Chang Gung Medical Foundation, Taoyuan, Taiwan

Background: A recent study indicated the risk of incident heart failure may vary with different sodium glucose co-transporter 2 inhibitors (SGLT2i). However, nothing is known about the effect modifiers, e.g., patients' baseline renal functions and the history of atherosclerotic

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cardiovascular diseases (ASCVD), on the risk of hospitalization due to heart failure (hHF) in type 2 diabetes patients with different SGLT2i.

Objectives: To evaluate effect modifications from patients' renal functions and ASCVD history on the hHF risks between dapagliflozin and empagliflozin.

Methods: We conducted a retrospective cohort study by analyzing a multi-institutional electronic medical records database, Chang Gung Research Database, containing approximately 1.3 million patients (6% of the Taiwan population). We included type 2 diabetes patients newly receiving dapagliflozin or empagliflozin during 2016-2017. We followed patients from the initiation of SGLT2i to September 31, 2019. We censored patients at the date of hHF, death or last clinical visit. We performed multivariable logistic regression models to compare the hHF risks between dapagliflozin and empagliflozin. Specifically, we used the interaction terms in the regression models to examine possible effect modifications from patients' baseline renal functions (eGFR≥90 vs. eGFR<90 ml/min/1.73m^2) and the history of ASCVD (with vs. without).

Results: We included 6,518 dapagliflozin and 7,940 empagliflozin new users in the analysis. The mean age was 58.6 (SD 11.7) and 59.9 (SD 11.9) years old among dapagliflozin and empagliflozin new users, respectively. Compared to empagliflozin, the adjusted hazard ratio (HR) of hHF was 0.71 (95% CI 0.55-0.92) for dapagliflozin. We found patients' renal functions modified the hHF risks between dapagliflozin and empagliflozin (p value for interaction was 0.01). Specifically, compared to empagliflozin, the adjusted HR was 0.42 (95% CI: 0.25-0.68) and 0.89 (95% CI: 0.66-1.20) for dapagliflozin new users with eGFR≥90 and eGFR<90 ml/min/1.73m^2, respectively. However, we did not observe any interaction of the history of ASCVD with the hHF risks between dapagliflozin and empagliflozin (p value for interaction was 0.24).

Conclusions: patients' baseline renal functions may modify the hHF risks between SGLT2 inhibitors, while the ASCVD history does not. Taking patients' renal functions into account before selecting dapagliflozin or empagliflozin may be important to better reduce hHF risks in type 2 diabetes patients in clinical practice.

4245 | Risk of breastfeeding newborns by hepatitis B surface antigen and hepatitis B E antigen positive mothers

Zhe Chen and Lingli Zhang

West China Second University Hospital, Sichuan University, Chengdu, China

Background: Nowadays the vertical transmission rate of hepatitis B virus (HBV) decreases significantly in HBsAg positive mothers after newborns receive immunization. But vertical transmission of HBV may still occur in 5-10% in HBsAg and HBeAg positive mothers.

Objectives: This study aims at evaluating the risk of breastfeeding newborns by HBsAg and HBeAg positive mothers in mother-to-child transmission (MTCT).

Methods: Seven electronic databases and three clinical trial registry platforms were searched and the deadline was December 2019. Cohort studies evaluating the risk of breastfeeding in HBsAg and HBeAg positive mothers were included by two reviewers. The Newcastle-Ottawa was applied to assessing the risk of bias. The outcomes were analyzed by Review Manager 5.3 software and expressed as relative risk (RR) or mean difference (MD) with 95% confidence interval (CI). Heterogeneity was assessed with I-squared (I^2) statistics.

Results: 17 cohort studies involving 2256 newborns were included in the meta-analysis. Compared to formula milk group, the number of HBsAg positive newborns increased significantly in breast milk group [RR=1.46, 95%CI (1.11, 1.92), P=0.007]. When the HBV-DNA<10^3 in breast milk, there was no difference in the number of HBsAg positive newborns between formula milk group and breast milk group [RR=3.62, 95%CI (1.00, 13.07), P=0.05]. When the HBV-DNA>10^3 in breast milk, the number of HBsAg positive newborns increased significantly in breast milk group compared to formula milk group [RR=2.69, 95%CI (1.09, 6.61), P=0.003]. Meanwhile, there was no difference in the number of anti-HBs positive newborns between formula milk group and breast milk group [RR=0.93, 95%CI (0.86, 1.01), P=0.10].

Conclusions: From the extrapolation of the existing literature, despite newborns received immunoprophylaxis, the risk of breastfeeding newborns by HBsAg and HBeAg positive mothers was still higher than formula feeding.

4286 | Societal impact for patients with psoriasis: A nationwide Swedish register study

Marie Linder

Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

Background: Psoriasis is a common immune-mediated chronic inflammatory disease with worldwide impact on men and women of all ages, affecting 2-4% of the Nordic population. Psoriasis has a significant negative impact on health status, increases community resource use and health care consumption.

Objectives: To observe differences in education, income, employment status, marital status, healthcare consumption and drug utilization between psoriasis patients and a matched reference cohort.

Methods: Cohort study following socioeconomic status and healthcare consumption for patients with psoriasis in the Swedish national patient register. All individuals with a first diagnosis of psoriasis, including psoriatic arthritis (2002 to 2013) were followed until death, emigration or end of study (31/12-2016). Outcomes: time to first increase in education, income, employment status, marital status, health care consumption and drug utilization. Models were adjusted for matching (age, sex, county) and a simple comorbidity index (count of relevant comorbidities at baseline). Models for socioeconomic variables also included baseline education. Time to first increase in education was analyzed by Cox regression. All other outcome variables were compared over time (years) from 1 year before index date until end of follow-up. The corresponding generalized linear regression

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

models were further adjusted for calendar year and follow-up time. An interaction term for follow-up time*cohort was included for differences between cases and controls over time. Normal regression (log link function) was used to model mean income. Proportions of employed and married were compared by logistic regression. Mean number of outpatient visits, hospitalizations and prescriptions were modeled by negative binomial regression.

Results: 109803 patients were included, mean age 51.2 years, 53% women, 36% using topical corticosteroids, matched to 1.08 million controls. The greatest difference ($p<0.0001$) was employment at 2 to 10 years after index with 10% less patients being employed. For marital status, we found a statistically significant difference (1.4%, $p<0.01$) after 4 years, for the remaining time. Incidence rate ratios for outpatient visits stabilized between year 3 and 4 (1.75 to 0.96), whereas hospitalizations increased at year 5 (0.99 to 1.04).

Conclusions: Understanding of socioeconomic impact of psoriasis is extended by showing reductions in employment proportion. Patients treated before diagnosis implies diagnostic delay, so there is room for improvement in management. It is important to monitor healthcare utilization through at least 5 years.

4292 | The practice of early conversion from intravenous to oral antibiotic therapy in uncomplicated urinary and respiratory tract infections: Assessment and evaluation of clinical and economic outcomes in hospitalized patients

Anusha Bellapu[1], Preethi Shanmugam[1], Subeesh K Viswam[2], Vasista Sharma[1] and Stephy T Chacko[1]

[1]M.S.Ramaiah University of Applied Sciences, Bangalore, India; [2]M.S. Ramaiah University of Applied Sciences, Bangalore, India

Background: This study was conducted to evaluate the impact of intravenous (IV) to oral conversion of antibiotic therapy w.r.t clinical and economic outcomes.

Objectives: To identify potential study subjects eligible for early conversion of antibiotics and recommend timely conversion from IV to oral therapy. To compare the clinical and economic outcomes between the retrospective and prospective phases.

Methods: An ambispective study was carried out in department of General Medicine at a tertiary care hospital. This study constitutes two phases, Phase I (retrospective phase) where IV to oral conversion was done before active involvement of the clinical pharmacist. Phase II (prospective interventional phase) consists of active involvement of the clinical pharmacist with recommendations for early conversion of IV to oral. The two phases were compared for statistically significant differences using unpaired t-test for and chi-square test. The economic outcomes were compared between the two phases using cost-minimization analysis, cost burden analysis.

Results: In this study, 83 were in phase I and 88 in phase II. As per criteria for IV to oral switch71 (86%) of phase I and 84 (95%) in phase II were eligible for conversion. Out of which 13 (18%) of phase I and 66 (79%) of phase II were switched. The average length of hospital stay(LOHS) was found to be 4.4±0.7 compared to phase I ($p<0.005$). The duration of IV therapy was 2.7±1.5 and 5.2±1.8 days in phase II and phase I respectively. Most common type of conversion was step down therapy (77%) phase I and (73%) phase II followed by sequential and switch therapy. The reinfection rate and readmission was similar among both the phases ($p>0.05$). The mean cost of hospital stay was analyzed in both phases and was observed that there was a cost reduction of ₹2,118.51 (30.55 USD) in phase II when compared to Phase I. The cost incurred to patients was calculated using cost burden analysis and it was found to be decreased from ₹1,42,622 (2056.75 USD) in phase I to ₹32,333 (466.27 USD) in phase II. The extra number of IV therapy days decreased from 112 (phase I) to 35 days in (phase II).

Conclusions: This study emphasizes that the practice of conversion from IV to oral antibiotic therapy has a considerable impact on clinical and economic outcomes amongst hospitalized inpatients. This study demonstrates a decrease in LOHS and economic burden if predefined switch criteria of IV to oral conversion are practiced meticulously.

4313 | Pharmaceutical health outcomes and policy curricula among Arab countries: An evaluation of 191 academic institutions

Eman Alghamdi[1], Thamer Alshammary[1,2] and Omar Albalawi[1]

[1]Saudi Food and Drug Authority, Riyadh, Saudi Arabia; [2]King Saud University, Riyadh, Saudi Arabia

Background: Pharmaceutical health outcomes and policy is a very fast growing area that is needed in the healthcare culture and has a positive impact on healthcare systems

Objectives: To examine the availability of teaching curricula, type and extent of pharmaceutical health outcomes and policy subjects (i.e. pharmacoepidemiology (PEPI), pharmacovigilance (PV), and Pharmacoeconomics (PE)) in the academic institutions among the 22 Arab countries

Methods: A cross sectional study conducted in the period from 2019-2020. The majority of the institutions among Arab countries were reviewed to list all pharmacy colleges. Then, the colleges' websites were reviewed to examine the study plan, type and extent of these subjects. Five criteria were utilized to assess these subjects; 1) full time mandatory, 2) full time elective, 3) partial mandatory, 4) partial elective, and 5) not offered. Full time means the subject is given as sole course while the partial time means it is part of another main course. The descriptive analyses were conducted using statistical analysis software (SAS®)

Results: About 191 colleges were screened during the study period. Of those, 150 (78.5%) institutions were included in the study and their curriculum was extracted, while, 41 (21.5%) institutions excluded due to the unavailability of their website. The teaching type and extent of the three subjects varied widely among different colleges. Eighty-eight (58.7%) colleges offered PE course, which was the highest offered subjects. Of these, 73 (83 %) colleges have the subject either

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

as full mandatory 40 (54.7%) or as partial mandatory 33 (45.3%). While, 15 (17%) colleges have the PE as elective, in either full or partial elective in 73% and 27%, respectively. On the other hand, PEPI was offered in 50 (33%) colleges, 43 (86%) colleges offered the subject as a mandatory course. It was taught as an elective subject in 7 (14%) colleges, of these 3 (43%) as full elective and 4 (47%) as a partial elective. Lastly, only 22 (15%) colleges provided PV course. The majority were having the subject as partial mandatory 12 (54.5%), followed by full elective 6 (27%), full mandatory 2 (9%), and partially elective 2 (9%). All colleges teach the three courses in the final two years

Conclusions: Pharmaceutical health outcomes and policy specialties were taught in a few colleges among the Arabic countries and still considered in the infancy stage. Providing a well-structured program to pharmacy students can help countries to establish an integrated scientific community that can enhance the safe use of medicine and starts applying PE evidence to healthcare decision making

4315 | Impact of the ICD-10-CM transition on claims-based severe sepsis events among US medicare enrollees

Tiffany S. Woodworth, Kerrin Gallagher, Erik Gunnarsson and Joseph Menzin

Boston Health Economics, Boston, MA

Background: Severe sepsis algorithms using administrative claims encoded in International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) have high positive predictive value, but low sensitivity, resulting in use of clinical data to better assess true cases. Availability of clinical data may be limited. ICD-10-CM transition provides an opportunity to characterize the impact of coding changes on claims-defined events.

Objectives: To characterize trends of severe sepsis events using administrative claims data over the ICD-9/10-CM transition period.

Methods: A trend analysis was conducted using a 5% sample of Medicare Fee-for-Service claims data to examine severe sepsis events during 783,184 hospitalizations from January 2014 - March 2016 among Medicare-enrolled patients ≥65 years with no evidence of commercial coverage. Six algorithms were used to examine severe sepsis trends over each ICD era: 2 well-known validated ICD-9-CM-based algorithms (Angus-9, Martin-9); each algorithm forward-backward mapped to ICD-10-CM codes (Angus-10, Martin-10); and use of only explicit ICD-9-CM or ICD-10-CM codes for *severe sepsis* and *septic shock* (Explicit-9, Explicit-10). We calculated the monthly proportion of severe sepsis among all hospitalizations during the study period and visually compared trends. We also calculated severe sepsis prevalence and confidence intervals for the first 6-month period of ICD-10 transition (October 2015 to March 2016) and compared ICD-9-defined prevalence during the same months in 2015.

Results: Consistent with published studies, ICD-9-defined severe sepsis over 6 months was highest for Angus-9 definition (25.9 [25.7, 26.2] per 100 hospitalizations). Prevalence for Martin-9 and Explicit-9 were 10.7 [10.5, 10.8] and 5.0 [4.9, 5.1], respectively. ICD-10-defined conversions over the 1st 6 months of transition yielded slightly higher results for Explicit-10 (5.2 [5.1,5.3]) and Martin-10 (11.0 [10.9,11.2]). Angus-10 was slightly less than Angus-9 (25.3 [25.1,25.6]). For all algorithms, monthly capture of severe sepsis during hospitalizations appeared stable between January 2014 through March 2016.

Conclusions: Though a slight increase in explicit sepsis coding was observed, trends of claims-defined severe sepsis remained stable over the ICD-10-CM transition. These preliminary findings suggest that the transition had minimal impact on identification of severe sepsis. ICD-10-based algorithms may be reasonably used to define cohorts, but clinical data may be required for sepsis surveillance.

4354 | A Bayesian analysis of observational studies: Theoretical and practical considerations

Gisèle Nakhlé[1,2], James Brophy[3,4], Paul Khairy[5,6,7], Jacques LeLorier[8,2,7], Christel Renoux[9,10,2] and Patrick Bélisle[5]

[1]CHUM Research Center, Montreal, QC, Canada; [2]the Canadian Network for Observational Drug Effect Studies (CNODES), Montreal, QC, Canada; [3]Centre for Health Outcomes Research, McGill University, Montreal, QC, Canada; [4]Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, QC, Canada; [5]Montreal Heart Institute, Montreal, QC, Canada; [6]Clinical Epidemiology and Outcomes Research, Montreal Health Innovations Coordinating Center, Montreal, QC, Canada; [7]Université de Montréal, Montreal, QC, Canada; [8]Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, QC, Canada; [9]Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, Canada; [10]Department of Epidemiology and Biostatistics, McGill University, Montreal, QC, Canada

Background: Bayesian analysis offers the ability to integrate previous evidence with current data to construct new knowledge in a given therapeutic field. Defining a "prior" can depend on the analyst's subjective beliefs and presents multiple challenges. As a case-study, a Bayesian analysis of a published trial was undertaken to illustrate considerations behind the choice of a prior and the methodology using different levels of skepticism in prior beliefs.

Objectives: Conduct a Bayesian meta-analysis (MA) using published data on the risk of ventricular tachycardia (VT) and sudden cardiac death (SCD) with use of domperidone in patients with Parkinson's disease (PD) to demonstrate: 1) a Bayesian approach to integrating prior data and 2) the use of probabilities rather than p-values for quantifying uncertainty in statistical inferences.

Methods: In assessing the association between domperidone and VT/SCD in patients with PD, we used the result (RR and CI) from a CNODES database analysis (7 Canadian provinces; 1 UK) as the observed data and combined it with either an uninformative (uniform) or informative prior (Bayesian RR (CI) from observational studies) to calculate the posterior probabilities (PP). We employed a Bayesian hierarchical approach using normal distributions to model the prior and observed data probabilities. Sensitivity analyses were conducted

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

using different weights of the prior data. We defined 4 thresholds of harm (>0%, >20%, >30%, >40%) and estimated the corresponding PP conditional on prior beliefs.

Results: The Bayesian approach with an uninformative prior yielded a RR of 1.28 (95% credible interval (CrI): 0.94 - 1.88) in comparison to the published frequentist RR of 1.22 (95% CI.: 0.99 - 1.50). With an informative prior, the RR was 1.51 (95% CrI: 1.19-2.0) when a weight of 100% was assigned, 1.41 (95% CrI: 1.10 - 1.98) with a weight of 50%, and 1.31 (95% CrI: 1.01 - 1.93) with a weight of 10%. When harm was defined as >30% increased risk, the PPs were 89%, 72%, and 51% with priors weighed at 100%, 50%, and 10%. When harm was defined as >40% increased risk, corresponding PPs were 72%, 51%, and 33%, respectively.

Conclusions: While both frequentist and Bayesian approaches found that domperidone is associated with an increased risk of VT/SCD in patients with PD, only the Bayesian approach directly quantified the probability of various magnitudes of harm, conditional on prior beliefs. Two main advantages of the Bayesian approach are the ability to combine prior knowledge with new data and to report inferences in a probabilistic manner that may be of additional benefit to patients, providers and regulators.

4358 | Association of industry payments to physicians with pimavanserin prescribing and medicare expenditures

Hemalkumar B. Mehta[1], Thomas J. Moore[2] and G. Caleb Alexander[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;*
[2]*Institute for Safe Medication Practices, Alexandria, VA*

Background: Pharmaceutical industry payments to physicians can influence physician's prescribing behavior. Pimavanserin was approved for Parkinson's disease psychosis. Product approval was based on a single trial suggesting a small treatment effect and occurred after three prior trials failed to meet prespecified endpoints. Post-marketing surveillance has also raised concerns regarding pimavanserin's safety.

Objectives: To quantify the association between industry payments to physicians for pimavanserin, pimavanserin prescribing and Medicare expenditures for its use.

Methods: This retrospective cross-sectional study linked Centers for Medicare and Medicaid Services (CMS) Open Payments and CMS Part D Prescriber Data from 2016 and 2017. We used Open Payments to extract pimavanserin-related payments to physicians for food, travel and lodging, speaking, consulting and education. Part D Prescriber Data was used to quantify pimavanserin prescription volume and pimavanserin Medicare expenditures. We constructed Poisson regression models to quantify the association between physician payments and pimavanserin prescribing. We modeled the association of physician payments with Medicare expenditures for pimavanserin using linear regression.

Results: In 2016 and 2017, 1,609 physicians ordered 43,165 pimavanserin prescriptions incurring $82,376,713 in Medicare expenditures. Overall, 45% of these physicians received $6,369,922 in payments - $5,615,470 for speaking, consulting and education, and $754,452 for food, travel and lodging. Physicians receiving payments wrote 47% more prescriptions (32 vs. 22 mean scripts, p<0.001), and 17% more expensive prescriptions ($2,041 vs. $1,749 mean Medicare expenditure, p<0.001) than those who did not receive payments. Physicians receiving no payments prescribed a median of 16 prescriptions, whereas those receiving $100,000 or more in payments prescribed a median of 96 prescriptions. Each $10,000 of physician payments was associated with increased pimavanserin prescribing by 14% (incident rate ratio 1.14, 95% confidence interval [CI] 1.13-1.14). Each $1 spent on physician payment by the manufacturer was associated with a $1.76 (95% CI $1.62-$1.90) increase in Medicare pimavanserin expenditures. Food, travel and lodging payments had a greater association with pimavanserin prescribing and Medicare expenditures than speaking, consulting and education payments.

Conclusions: Our study shows extensive payments to physicians that were associated with increased number and costs of pimavanserin prescriptions.

4466 | Real-world treatment patterns and adherence of first-line anti-diabetic treatments among T2dm patients using Japanese claims data

Jocelyn Ruoyi Wang, Amanda Patrick, Pattra Mattox and Ashley Jaksa
Aetion Inc., Boston, MA

Background: Global regulatory agencies traditionally use randomized-controlled trials (RCT) to inform decisions. However, a discrepancy often exists between pre-marketing RCT efficacy data and the effectiveness data from real-world evidence (RWE). The Japan Clinical Practice Guideline for Diabetes recommends individualizing first-line treatment with an oral hypoglycemic agent based on patient conditions and safety profiles. Furthermore, medication adherence is critical to ensuring long-term glycemic control.

Objectives: To understand the treatment pathways and real-world adherence to anti-glycemic agents among type-2 diabetic (T2D) patients using a Japanese administrative database.

Methods: We identified newly-diagnosed T2D patients initiating first-line treatment using the Japanese Medical Data Center (JMDC) claims database (2014-2018). JMDC includes inpatient, outpatient, pharmacy claims and Diagnosis Procedure Combination (DPC) codes. Patients <18 years and those with prior anti-diabetic treatment were excluded. Patients were assessed for adherence (proportion of days covered [PDC]>80%) and persistence (i.e., probability of persistency during the assessment period) of first-line treatment during a one-year follow-up. Treatment change (addition, switching, and/or discontinuation) was also evaluated.

Results: Among 5,583 patients, the mean age was 55 years; 71.1% were male. Transition-based treatment pathway showed that dipeptidyl peptidase 4 inhibitors (DPP4i 49.5%) was the most

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

common first-line treatment, followed by metformin (26.6%), and SGLT2-i (10.1%). Nine different treatment pathways were observed for second-line therapy intensification. One-year persistence ranged from 29%-62%; SLGT2-i (62%) and DPP4-i (53%) users had the highest persistence. PDC at one year ranged from 60%-84%, with the highest values in SGLT2-i (84%) and metformin (81%) users.

Conclusions: While most newly-diagnosed T2D patients in Japan received DPP4i as first-line treatment, DPP-4i adherence was suboptimal. New users of SGLT2i, the third most common first-line antiglycemic, demonstrated higher adherence and persistence after one year of follow-up compared to the other antidiabetics. Complex treatment patterns of type-2 diabetic patients -- with frequent switching and less-than-optimal persistence -- highlights the utility of generating RWE from real-world data (RWD) sources to provide contextual information on routine clinical practice.

4492 | Multi-state Markov modelling of long-term outcomes using machine-learned dynamic Bayesian networks

Alind Gupta[1], Darren Brenner[2] and Paul Arora[1]
[1]*Cytel Inc, Toronto, ON, Canada;* [2]*University of Calgary, Calgary, AB, Canada*

Background: Patient-level heterogeneity in response to treatment remains a major challenge in cancer immunotherapy. Long-term individual-level modelling of survival, tumour response and safety outcomes jointly can help improve efficacy and durable clinical benefits.

Objectives: To develop a dynamic Bayesian network model for multivariate risk prediction, survival modelling and long-term simulations of immunotherapy patients using a simulated trial dataset.

Methods: A simulated randomized clinical trial dataset for immunotherapy of patients with renal cell carcinoma was used for analysis. We machine learned a dynamic Bayesian network from censored data with incorporation of prior knowledge. Classification performance, probability calibration, goodness-of-fit metrics and prognostic variables were calculated.

Results: The machine-learned graphical model encoded expected relationships between variables. Visual and numerical goodness-of-fit checks for survival extrapolations showed that the model fitted data well and was appropriate. Probability calibration was <10% from ideal. Classification performance for overall survival was high (c-statistic ~0.85) soon after treatment initiation and gradually plateaued over time. Prognostic variables were calculated by treatment arm for overall survival and severe adverse events.

Conclusions: Dynamic Bayesian network model was useful for transparently representing joint relationships between variables, for multivariate risk prediction and long-term extrapolations that can be used in economic evaluations for health technology assessments.

4520 | Real-world cost-effectiveness of direct oral anticoagulants in the Quebec setting

Philippe Lachapelle[1], Anne Holbrook[2], Mireille Mireille Schnitzer[3], Jean-Éric Tarride[4], Christel Renoux[5], Brian J. Potter[3], Alexis Matteau[3], Denis Talbot[1], Madeleine Durand[3] and Jason Guertin[1]
[1]*Université Laval, Québec City, QC, Canada;* [2]*McMaster University, Hamilton, ON, Canada;* [3]*Université de Montréal, Montréal, QC, Canada;* [4]*McMaster University, Hamilton, QC, Canada;* [5]*McGill University, Montréal, QC, Canada*

Background: Atrial fibrillation (AF) is the most common cardiac arrhythmia, affecting approximately 350,000 Canadians. AF increases the risk of stroke and systemic embolism, a risk substantially lowered by oral anticoagulants (OACs). Direct oral anticoagulants (DOACs) have been rapidly replacing warfarin as the preferred treatment in clinical practice. Previous economic evaluations comparing DOACs and warfarin were all based on RCT data. A full economic analysis based in clinical practice, has yet to be published.

Objectives: To conduct a patient level real-world economic evaluation of warfarin versus DOACs.

Methods: We conducted a cost-effectiveness analysis based on data from the Régie d'assurance maladie du Québec (RAMQ) and the Ministère de la Santé et des Services Sociaux (MSSS), using a MSSS perspective. The study population included all adults aged 18 years and older newly initiated on an OAC for non-valvular atrial fibrillation in the Province of Québec between April 1st 2011 and March 31st 2017. The incremental cost-effectiveness ratio (ICER) of warfarin versus DOAC was measured as the incremental cost per incremental life-year gained. The exposure classification was based on an intention to treat approach. Costs included all medical fee-for-service or medication claims, hospitalizations and emergency room visits. The follow-up period was censored at five years and served as the time horizon of the analysis. The adjusted ICER will be obtained using inverse probability of treatment weighting combined with the high dimensional propensity score (hdPS) algorithm and will account for data censoring. To measure uncertainty on cost and effectiveness parameters, nonparametric bootstrap with replacement was applied. Cost-effectiveness acceptability curves (CEAC) were used to summarize the uncertainty at different willingness to pay ratios.

Results: 60,093 patients were included in the base case analysis (38,579 for DOACs and 21,514 for warfarin). Preliminary results in the unadjusted cohort suggest that the ICER of warfarin versus DOACs was $23,051 per life year gained, warfarin being both more effective (.81 year) and more costly ($18,749) than DOACs. At a willingness to pay threshold of $50,000 per life year gained, the probability that the anticoagulation therapy initiated on DOACs was cost-effective is 0%.

Conclusions: Preliminary results favor the use of warfarin over DOACs. However, further analyses (e.g., adjustment for confounding bias and accounting for data censoring) are required before concluding on the true value of DOACs versus warfarin.

10991557, 2020, S3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pds.5114 by Marmara University, Wiley Online Library on [17/03/2023]. 4538 | Selection bias associated with lab records in administrative claims from the United States

Kathleen M. Andersen[1,2], Derek K. Ng[1], Michael J. Blaha[1,3], G. Caleb Alexander[1,2,4] and Jodi B. Segal[1,2,4,5]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Center for Drug Safety & Effectiveness, Baltimore, MD;* [3]*The Ciccarone Center for the Prevention of Cardiovascular Disease, Baltimore, MD;* [4]*Division of General Internal Medicine, Johns Hopkins School of Medicine, Baltimore, MD;* [5]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Administrative claims are used in the United States for population-level analyses of drug utilization, safety and effectiveness. While clinical encounters and prescription dispensations are well captured, data have limited coverage of laboratory test results. Ongoing monoclonal antibody PCSK9 inhibitor (PCSK9i) treatment requires LDL cholesterol monitoring, therefore PCSK9i users represent a study population in which we can evaluate the generalizability of lab result availability.

Objectives: To evaluate whether the subset of PCSK9i users with available LDL values in IBM MarketScan® Commercial Claims and Encounters Database represents the larger pool of PCSK9i users without available lab data.

Methods: Persons with at least one dispensation for alirocumab or evolocumab were extracted between July 2015 (month of FDA approval) and December 2017. Persons were classified as having at least one LDL result pre- or post-initiation, or no lab result data. We used standardized mean differences (SMD) >10% to define significant differences between groups in a sample size independent manner.
