ABSTRACT

Chanarin Dorfman syndrome is a multisystem, very rare, autosomal recessive lipid storage disorder, characterized by the accumulation of lipid vacuoles in neutrophils, and was first described by Dorfman in 1974. Due to a mutation in the ABHD5 gene of the short arm of chromosome 3, lipid is stored in the granulocytes at various sites in the human body, such as the muscle, liver, eye, ear, central nervous system, and bone marrow. Clinically, the disease is presented with ichthyosis, hearing loss, hepatomegaly, splenomegaly, cirrhosis, cataract, keratopathy, myopathy, and mental retardation. A 38-year-old male patient was referred to our Internal Medicine Clinic for consultation with laboratory findings as follows: high aspartate aminotransferase (AST; 203 U/L), alanine aminotransferase (ALT; 151 U/L), gamma-glutamyl transferase (GGT; 167 U/L), creatine kinase (CK; 1127 U/L) levels and low platelet levels (108000). After ultrasonography and gastroscopy, the patient was diagnosed with liver cirrhosis. Bilateral mixed-type hearing loss on audial tests and bilateral punctuate keratopathy, ectropion, and cataract in the left eye on ophthalmological tests were found. For the definitive diagnosis of Chanarin Dorfman syndrome, peripheral blood was examined, which revealed lipid accumulation in the neutrophils (Jordan's anomaly). We emphasize that if a patient has unusual findings, such as ichthyosis, hearing loss, hepatomegaly, splenomegaly, cirrhosis, cataract, keratopathy, myopathy, and mental retardation, the possibility of Chanarin Dorfman syndrome should be considered.

Keywords: Ichthyosis, fibrosis, cataract, ectropion, hearing loss, lipid droplets

INTRODUCTION

Chanarin-Dorfman syndrome is a multisystem, autosomal recessive lipid storage disorder, characterized by the accumulation of lipid vacuoles in neutrophils, and was first described by Dorfman in 1974. Due to the mutation in the ABHD5 gene of the short arm of chromosome 3, lipid is stored in granulocytes at various sites, such as the muscle, liver, eye, ear, central nervous system, and bone marrow. Here, a case with ichthyosis, liver cirrhosis, cataract, keratopathy, ectropion, elevated muscle enzyme levels, minimal loss of hearing, and lipid storage in peripheral blood neutrophils is presented (1-4).

CASE PRESENTATION

A 38-year-old male patient who has been followed since childhood due to ichthyosis at a dermatology clinic was sent to the Internal Medicine Clinic for consultation with laboratory findings of elevated aspartate aminotransferase (AST; 203 U/L), alanine aminotransferase (ALT; 151 U/L), gamma-glutamyl transferase (GGT; 167 U/L), and creatine kinase (CK; 1127 U/L) levels (Figures 1-3). Additional test results, including partial thrombo-

plastin time, activated partial thromboplastin time, and International Normalized Ratio, were within normal limits, except low platelet levels (108000). On ultrasound examination, the liver was found atrophic with irregular edges and had high parenchymal echogenicity and coarse granular appearance, and the spleen was 18-cm larger. Gastroscopy revealed esophageal varices, and the case was diagnosed as liver cirrhosis. Results of serological assay for viral hepatitis and autoimmune markers for the etiology of cirrhosis were negative. As the concomitance of ichthyosis, liver cirrhosis, and elevated muscle enzyme levels were suspicious of a syndrome, the patient was referred for eye and ear examinations. In audial tests, bilateral mixed-type hearing loss and in ophthalmological examinations, bilateral punctuate keratopathy, ectropion, and cataract formation in the left eye were found. Keratitis ichthyosis deafness syndrome and Chanarin Dorfman syndrome were considered for differential diagnosis. Keratitis ichthyosis deafness syndrome was excluded after genetic investigation. For the diagnosis of Chanarin Dorfman syndrome, peripheral blood was examined, which revealed lipid accumulation

in the neutrophils, a pathognomonic finding of this syndrome (Jordan's anomaly; Figure 4). As a result, the case was diagnosed as Chanarin Dorfman syndrome. Due to social restrictions, further genetic testing could not be done to verify the diagnosis.

DISCUSSION

Chanarin Dorfman syndrome is a very rare disorder, with a literature search until 2015 including only <100 cases (5). The autosomal recessive syndrome developing due to ABHD5/CGI58 gene mutation is more prevalent in the Mediterranean and Middle East countries (6).

Figure 1. Ichthyosis

Figure 3. Ichthyosis

Figure 2. Keratopathy, ectropion, and cataract

Figure 4. Lipid accumulation in the neutrophils (Jordan's anomaly)

Lipid accumulation in various tissues occurs as a result of abnormal catabolism of triacylglycerols. Normally, CGI58 protein found on the surface of cytoplasmic lipid droplets activates lipase and leads to lipolysis. Mutations in the ABHD5/CGI58 gene prevent lipolysis, consequently leading to lipid accumulation in leucocytes, fibroblasts, liver, and muscle cells. Clinically, the disease is presented with ichthyosis, hearing loss, hepatomegaly, splenomegaly, cirrhosis, cataract, myopathy, and mental retardation. (7-10). Skin findings include dryness, erythema, hyperkeratosis, and ichthyosis. Our patient was under treatment for ichthyosis since early childhood.

Although hearing loss has been generally defined as the bilateral neurosensory type in earlier reports, our patient had a bilateral mixed-type minimal hearing loss.

Liver involvement is mostly seen as hepatomegaly, fatty liver, and elevated liver enzyme levels and is rarely accompanied with splenomegaly. In our case, liver cirrhosis with splenomegaly was detected.

Eye involvement has been found as cataract formation in 46% of reported cases. Besides, nystagmus, strabismus, or ectropion may be present. Our patient had cataract, ectropion, and punctate keratopathy.

Although myopathy can be seen in the form of muscle weakness, cardiomyopathy, or aortic insufficiency, our case showed only elevated creatine kinase levels and no muscle weakness or cardiac pathology.

Regarding central nervous system involvement, ataxia, mental retardation, and microcephaly have been reported; however, our patient had none of these disorders.

Elevated serum lipid levels have been usually detected in some previous reports, however, in our case, total cholesterol and triglyceride levels were found within normal ranges, whereas high-density lipoprotein, low-density lipoprotein, and cholesterol levels were low. In lipid electrophoresis, no abnormality was noted, except low pre-beta lipoprotein level (11).

Additionally, final diagnosis in our case was determined with peripheral blood examination, which revealed lipid vacuoles in neutrophils.

After the diagnosis of Chanarin Dorfman syndrome, a multidisciplinary approach of various specialties, includ-

ing internal medicine, dermatology, ophthalmology, nutrition, and gastroenterology, should contribute to the treatment, similar to that in the prediagnostic phase. Diet is especially one of the most important components of therapy. Under the guidance of a dietician, our patient started to have a diet that lacked long-chain fatty acids and was rich in medium-chain fatty acids. Ursodeoxycholic acid (Ursofalk; Ali Raif, Ursactive; Pharmactive) 250 mg 3×1/day per oral and local therapy for ichthyosis provided additional support. Long-term topical therapy was administered for bilateral punctate keratopathy. Our patient is still under regular follow-up and treatment.

CONCLUSION

We emphasize that in case of different multisystemic findings, such as ichthyosis, hearing loss, hepatomegaly, splenomegaly, cirrhosis, cataract, keratopathy, myopathy, and mental retardation, physicians should suspect Chanarin Dorfman syndrome.
